1 Probability and Distributions	1
1.1 Introduction	1
1.2 Sets	3
1.2.1 Review of Set Theory	4
1.2.2 Set Functions	7
1.3 The Probability Set Function	12
1.3.1 Counting Rules	16
1.3.2 Additional Properties of Probability	18
1.4 Conditional Probability and Independence	23
1.4.1 Independence	28
1.4.2 Simulations	31
1.5 Random Variables	37
1.6 Discrete Random Variables	45
1.6.1 Transformations	47
1.7 Continuous Random Variables	49
1.7.1 Quantiles	51
1.7.2 Transformations	53
1.7.3 Mixtures of Discrete and Continuous Type Distributions	56
1.8 Expectation of a Random Variable	60
1.8.1 R Computation for an Estimation of the Expected Gain	65
1.9 Some Special Expectations	68
1.10 Important Inequalities	78
2 Multivariate Distributions	85
2.1 Distributions of Two Random Variables	85
2.1.1 Marginal Distributions	89
2.1.2 Expectation	93
2.2 Transformations: Bivariate Random Variables	100
2.3 Conditional Distributions and Expectations	109
2.4 Independent Random Variables	117
2.5 The Correlation Coefficient	125
2.6 Extension to Several Random Variables	134

2.6.1	*Multivariate Variance-Covariance Matrix	140
2.7	Transformations for Several Random Variables	143
2.8	Linear Combinations of Random Variables	151
3	Some Special Distributions	155
3.1	The Binomial and Related Distributions	155
3.1.1	Negative Binomial and Geometric Distributions	159
3.1.2	Multinomial Distribution	160
3.1.3	Hypergeometric Distribution	162
3.2	The Poisson Distribution	167
3.3	The Γ , χ^2 , and β Distributions	173
3.3.1	The χ^2 -Distribution	178
3.3.2	The β -Distribution	180
3.4	The Normal Distribution	186
3.4.1	*Contaminated Normals	193
3.5	The Multivariate Normal Distribution	198
3.5.1	Bivariate Normal Distribution	198
3.5.2	*Multivariate Normal Distribution, General Case	199
3.5.3	*Applications	206
3.6	t - and F -Distributions	210
3.6.1	The t -distribution	210
3.6.2	The F -distribution	212
3.6.3	Student's Theorem	214
3.7	*Mixture Distributions	218
4	Some Elementary Statistical Inferences	225
4.1	Sampling and Statistics	225
4.1.1	Point Estimators	226
4.1.2	Histogram Estimates of pmfs and pdfs	230
4.2	Confidence Intervals	238
4.2.1	Confidence Intervals for Difference in Means	241
4.2.2	Confidence Interval for Difference in Proportions	243
4.3	*Confidence Intervals for Parameters of Discrete Distributions	248
4.4	Order Statistics	253
4.4.1	Quantiles	257
4.4.2	Confidence Intervals for Quantiles	261
4.5	Introduction to Hypothesis Testing	267
4.6	Additional Comments About Statistical Tests	275
4.6.1	Observed Significance Level, p -value	279
4.7	Chi-Square Tests	283
4.8	The Method of Monte Carlo	292
4.8.1	Accept–Reject Generation Algorithm	298
4.9	Bootstrap Procedures	303
4.9.1	Percentile Bootstrap Confidence Intervals	303
4.9.2	Bootstrap Testing Procedures	308
4.10	*Tolerance Limits for Distributions	315

5 Consistency and Limiting Distributions	321
5.1 Convergence in Probability	321
5.1.1 Sampling and Statistics	324
5.2 Convergence in Distribution	327
5.2.1 Bounded in Probability	333
5.2.2 Δ -Method	334
5.2.3 Moment Generating Function Technique	336
5.3 Central Limit Theorem	341
5.4 *Extensions to Multivariate Distributions	348
6 Maximum Likelihood Methods	355
6.1 Maximum Likelihood Estimation	355
6.2 Rao–Cramér Lower Bound and Efficiency	362
6.3 Maximum Likelihood Tests	376
6.4 Multiparameter Case: Estimation	386
6.5 Multiparameter Case: Testing	395
6.6 The EM Algorithm	404

7.1 Measures of Quality of Estimators	413
7.2 A Sufficient Statistic for a Parameter	419
7.3 Properties of a Sufficient Statistic	426
7.4 Completeness and Uniqueness	430
7.5 The Exponential Class of Distributions	435
7.6 Functions of a Parameter	440
7.6.1 Bootstrap Standard Errors	444
7.7 The Case of Several Parameters	447
7.8 Minimal Sufficiency and Ancillary Statistics	454
7.9 Sufficiency, Completeness, and Independence	461
8 Optimal Tests of Hypotheses	469
8.1 Most Powerful Tests	469
8.2 Uniformly Most Powerful Tests	479
8.3 Likelihood Ratio Tests	487
8.3.1 Likelihood Ratio Tests for Testing Means of Normal Distributions	488
8.3.2 Likelihood Ratio Tests for Testing Variances of Normal Distributions	495
8.4 *The Sequential Probability Ratio Test	500
8.5 *Minimax and Classification Procedures	507
8.5.1 Minimax Procedures	507
8.5.2 Classification	510

9 Inferences About Normal Linear Models	515
9.1 Introduction	515
9.2 One-Way ANOVA	516
9.3 Noncentral χ^2 and F -Distributions	522
9.4 Multiple Comparisons	525
9.5 Two-Way ANOVA	531
9.5.1 Interaction between Factors	534
9.6 A Regression Problem	539
9.6.1 Maximum Likelihood Estimates	540
9.6.2 *Geometry of the Least Squares Fit	546
9.7 A Test of Independence	551
9.8 The Distributions of Certain Quadratic Forms	555
9.9 The Independence of Certain Quadratic Forms	562
10 Nonparametric and Robust Statistics	569
10.1 Location Models	569
10.2 Sample Median and the Sign Test	572
10.2.1 Asymptotic Relative Efficiency	577
10.2.2 Estimating Equations Based on the Sign Test	582
10.2.3 Confidence Interval for the Median	584
10.3 Signed-Rank Wilcoxon	586
10.3.1 Asymptotic Relative Efficiency	591
10.3.2 Estimating Equations Based on Signed-Rank Wilcoxon	593
10.3.3 Confidence Interval for the Median	594
10.3.4 Monte Carlo Investigation	595
10.4 Mann–Whitney–Wilcoxon Procedure	598
10.4.1 Asymptotic Relative Efficiency	602
10.4.2 Estimating Equations Based on the Mann–Whitney–Wilcoxon	604
10.4.3 Confidence Interval for the Shift Parameter Δ	604
10.4.4 Monte Carlo Investigation of Power	605
10.5 *General Rank Scores	607
10.5.1 Efficacy	610
10.5.2 Estimating Equations Based on General Scores	612
10.5.3 Optimization: Best Estimates	612
10.6 *Adaptive Procedures	619
10.7 Simple Linear Model	625
10.8 Measures of Association	631
10.8.1 Kendall's τ	631
10.8.2 Spearman's Rho	634
10.9 Robust Concepts	638
10.9.1 Location Model	638
10.9.2 Linear Model	645

11 Bayesian Statistics	655
11.1 Bayesian Procedures	655
11.1.1 Prior and Posterior Distributions	656
11.1.2 Bayesian Point Estimation	658
11.1.3 Bayesian Interval Estimation	662
11.1.4 Bayesian Testing Procedures	663
11.1.5 Bayesian Sequential Procedures	664

Preface

We have made substantial changes in this edition of *Introduction to Mathematical Statistics*. Some of these changes help students appreciate the connection between statistical theory and statistical practice while other changes enhance the development and discussion of the statistical theory presented in this book.

Many of the changes in this edition reflect comments made by our readers. One of these comments concerned the small number of real data sets in the previous editions. In this edition, we have included more real data sets, using them to illustrate statistical methods or to compare methods. Further, we have made these data sets accessible to students by including them in the free R package `hmcpkg`. They can also be individually downloaded in an R session at the url listed below. In general, the R code for the analyses on these data sets is given in the text.

We have also expanded the use of the statistical software R. We selected R because it is a powerful statistical language that is free and runs on all three main platforms (Windows, Mac, and Linux). Instructors, though, can select another statistical package. We have also expanded our use of R functions to compute analyses and simulation studies, including several games. We have kept the level of coding for these functions straightforward. Our goal is to show students that with a few simple lines of code they can perform significant computations. Appendix B contains a brief R primer, which suffices for the understanding of the R used in the text. As with the data sets, these R functions can be sourced individually at the cited url; however, they are also included in the package `hmcpkg`.

We have supplemented the mathematical review material in Appendix A, placing it in the document *Mathematical Primer for Introduction to Mathematical Statistics*. It is freely available for students to download at the listed url. Besides sequences, this supplement reviews the topics of infinite series, differentiation, and integration (univariate and bivariate). We have also expanded the discussion of iterated integrals in the text. We have added figures to clarify discussion.

We have retained the order of elementary statistical inferences (Chapter 4) and asymptotic theory (Chapter 5). In Chapters 5 and 6, we have written brief reviews of the material in Chapter 4, so that Chapters 4 and 5 are essentially independent of one another and, hence, can be interchanged. In Chapter 3, we now begin the section on the multivariate normal distribution with a subsection on the bivariate normal distribution. Several important topics have been added. This includes Tukey's multiple comparison procedure in Chapter 9 and confidence intervals for the correlation coefficients found in Chapters 9 and 10. Chapter 7 now contains a

discussion on standard errors for estimates obtained by bootstrapping the sample. Several topics that were discussed in the Exercises are now discussed in the text. Examples include quantiles, Section 1.7.1, and hazard functions, Section 3.3. In general, we have made more use of subsections to break up some of the discussion. Also, several more sections are now indicated by * as being optional.

Content and Course Planning

Chapters 1 and 2 develop probability models for univariate and multivariate variables while Chapter 3 discusses many of the most widely used probability models. Chapter 4 discusses statistical theory for much of the inference found in a standard statistical methods course. Chapter 5 presents asymptotic theory, concluding with the Central Limit Theorem. Chapter 6 provides a complete inference (estimation and testing) based on maximum likelihood theory. The EM algorithm is also discussed. Chapters 7–8 contain optimal estimation procedures and tests of statistical hypotheses. The final three chapters provide theory for three important topics in statistics. Chapter 9 contains inference for normal theory methods for basic analysis of variance, univariate regression, and correlation models. Chapter 10 presents nonparametric methods (estimation and testing) for location and univariate regression models. It also includes discussion on the robust concepts of efficiency, influence, and breakdown. Chapter 11 offers an introduction to Bayesian methods. This includes traditional Bayesian procedures as well as Markov Chain Monte Carlo techniques.

Several courses can be designed using our book. The basic two-semester course in mathematical statistics covers most of the material in Chapters 1–8 with topics selected from the remaining chapters. For such a course, the instructor would have the option of interchanging the order of Chapters 4 and 5, thus beginning the second semester with an introduction to statistical theory (Chapter 4). A one-semester course could consist of Chapters 1–4 with a selection of topics from Chapter 5. Under this option, the student sees much of the statistical theory for the methods discussed in a non-theoretical course in methods. On the other hand, as with the two-semester sequence, after covering Chapters 1–3, the instructor can elect to cover Chapter 5 and finish the course with a selection of topics from Chapter 4.

The data sets and R functions used in this book and the R package `hmcpkg` can be downloaded at the site:

Acknowledgements

Bob Hogg passed away in 2014, so he did not work on this edition of the book. Often, though, when I was trying to decide whether or not to make a change in the manuscript, I found myself thinking of what Bob would do. In his memory, I have retained the order of the authors for this edition.

As with earlier editions, comments from readers are always welcomed and appreciated. We would like to thank these reviewers of the previous edition: James Baldone, Virginia College; Steven Culpepper, University of Illinois at Urbana-Champaign; Yuichiro Kakihara, California State University; Jaechoul Lee, Boise State University; Michael Levine, Purdue University; Tingni Sun, University of Maryland, College Park; and Daniel Weiner, Boston University. We appreciated and took into consideration their comments for this revision. We appreciate the helpful comments of Thomas Hettmansperger of Penn State University, Ash Abebe of Auburn University, and Professor Ioannis Kalogridis of the University of Leuven. A special thanks to Patrick Barbera (Portfolio Manager, Statistics), Lauren Morse (Content Producer, Math/Stats), Yvonne Vannatta (Product Marketing Manager), and the rest of the staff at Pearson for their help in putting this edition together. Thanks also to Richard Ponticelli, North Shore Community College, who accuracy checked the page proofs. Also, a special thanks to my wife Marge for her unwavering support and encouragement of my efforts in writing this edition.

Chapter 1

Probability and Distributions

1.1 Introduction

In this section, we intuitively discuss the concepts of a probability model which we formalize in Section 1.3. Many kinds of investigations may be characterized in part by the fact that repeated experimentation, under essentially the same conditions, is more or less standard procedure. For instance, in medical research, interest may center on the effect of a drug that is to be administered; or an economist may be concerned with the prices of three specified commodities at various time intervals; or an agronomist may wish to study the effect that a chemical fertilizer has on the yield of a cereal grain. The only way in which an investigator can elicit information about any such phenomenon is to perform the experiment. Each experiment terminates with an *outcome*. But it is characteristic of these experiments that the outcome cannot be predicted with certainty prior to the experiment.

Suppose that we have such an experiment, but the experiment is of such a nature that a collection of every possible outcome can be described prior to its performance. If this kind of experiment can be repeated under the same conditions, it is called a **random experiment**, and the collection of every possible outcome is called the experimental space or the **sample space**. We denote the sample space by \mathcal{C} .

Example 1.1.1. In the toss of a coin, let the outcome tails be denoted by T and let the outcome heads be denoted by H . If we assume that the coin may be repeatedly tossed under the same conditions, then the toss of this coin is an example of a random experiment in which the outcome is one of the two symbols T or H ; that is, the sample space is the collection of these two symbols. For this example, then, $\mathcal{C} = \{H, T\}$. ■

Example 1.1.2. In the cast of one red die and one white die, let the outcome be the ordered pair (number of spots up on the red die, number of spots up on the white die). If we assume that these two dice may be repeatedly cast under the same conditions, then the cast of this pair of dice is a random experiment. The sample space consists of the 36 ordered pairs: $\mathcal{C} = \{(1, 1), \dots, (1, 6), (2, 1), \dots, (2, 6), \dots, (6, 6)\}$. ■

We generally use small Roman letters for the elements of \mathcal{C} such as a, b , or c . Often for an experiment, we are interested in the chances of certain subsets of elements of the sample space occurring. Subsets of \mathcal{C} are often called **events** and are generally denoted by capitol Roman letters such as A, B , or C . If the experiment results in an element in an event A , we say the event A has occurred. We are interested in the chances that an event occurs. For instance, in Example 1.1.1 we may be interested in the chances of getting heads; i.e., the chances of the event $A = \{H\}$ occurring. In the second example, we may be interested in the occurrence of the sum of the upfaces of the dice being “7” or “11;” that is, in the occurrence of the event $A = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1), (5, 6), (6, 5)\}$.

Now conceive of our having made N repeated performances of the random experiment. Then we can count the number f of times (the **frequency**) that the event A actually occurred throughout the N performances. The ratio f/N is called the **relative frequency** of the event A in these N experiments. A relative frequency is usually quite erratic for small values of N , as you can discover by tossing a coin. But as N increases, experience indicates that we associate with the event A a number, say p , that is equal or approximately equal to that number about which the relative frequency seems to stabilize. If we do this, then the number p can be interpreted as that number which, in future performances of the experiment, the relative frequency of the event A will either equal or approximate. Thus, although we *cannot* predict the outcome of a random experiment, we *can*, for a large value of N , predict approximately the relative frequency with which the outcome will be in A . The number p associated with the event A is given various names. Sometimes it is called the *probability* that the outcome of the random experiment is in A ; sometimes it is called the *probability* of the event A ; and sometimes it is called the *probability measure* of A . The context usually suggests an appropriate choice of terminology.

Example 1.1.3. Let \mathcal{C} denote the sample space of Example 1.1.2 and let B be the collection of every ordered pair of \mathcal{C} for which the sum of the pair is equal to seven. Thus $B = \{(1, 6), (2, 5), (3, 4), (4, 3), (5, 2)(6, 1)\}$. Suppose that the dice are cast $N = 400$ times and let f denote the frequency of a sum of seven. Suppose that 400 casts result in $f = 60$. Then the relative frequency with which the outcome was in B is $f/N = \frac{60}{400} = 0.15$. Thus we might associate with B a number p that is close to 0.15, and p would be called the probability of the event B . ■

Remark 1.1.1. The preceding interpretation of probability is sometimes referred to as the *relative frequency approach*, and it obviously depends upon the fact that an experiment can be repeated under essentially identical conditions. However, many persons extend probability to other situations by treating it as a rational measure of belief. For example, the statement $p = \frac{2}{5}$ for an event A would mean to them that their *personal* or *subjective* probability of the event A is equal to $\frac{2}{5}$. Hence, if they are not opposed to gambling, this could be interpreted as a willingness on their part to bet on the outcome of A so that the two possible payoffs are in the ratio $p/(1-p) = \frac{2}{5}/\frac{3}{5} = \frac{2}{3}$. Moreover, if they truly believe that $p = \frac{2}{5}$ is correct, they would be willing to accept either side of the bet: (a) win 3 units if A occurs and lose 2 if it does not occur, or (b) win 2 units if A does not occur and lose 3 if

it does. However, since the mathematical properties of probability given in Section 1.3 are consistent with either of these interpretations, the subsequent mathematical development does not depend upon which approach is used. ■

The primary purpose of having a mathematical theory of statistics is to provide mathematical models for random experiments. Once a model for such an experiment has been provided and the theory worked out in detail, the statistician may, within this framework, make inferences (that is, draw conclusions) about the random experiment. The construction of such a model requires a theory of probability. One of the more logically satisfying theories of probability is that based on the concepts of sets and functions of sets. These concepts are introduced in Section 1.2.

1.2 Sets

The concept of a *set* or a *collection* of objects is usually left undefined. However, a particular set can be described so that there is no misunderstanding as to what collection of objects is under consideration. For example, the set of the first 10 positive integers is sufficiently well described to make clear that the numbers $\frac{3}{4}$ and 14 are not in the set, while the number 3 is in the set. If an object belongs to a set, it is said to be an *element* of the set. For example, if C denotes the set of real numbers x for which $0 \leq x \leq 1$, then $\frac{3}{4}$ is an element of the set C . The fact that $\frac{3}{4}$ is an element of the set C is indicated by writing $\frac{3}{4} \in C$. More generally, $c \in C$ means that c is an element of the set C .

The sets that concern us are frequently *sets of numbers*. However, the language of sets of *points* proves somewhat more convenient than that of sets of numbers. Accordingly, we briefly indicate how we use this terminology. In analytic geometry considerable emphasis is placed on the fact that to each point on a line (on which an origin and a unit point have been selected) there corresponds one and only one number, say x ; and that to each number x there corresponds one and only one point on the line. This one-to-one correspondence between the numbers and points on a line enables us to speak, without misunderstanding, of the “point x ” instead of the “number x .” Furthermore, with a plane rectangular coordinate system and with x and y numbers, to each symbol (x, y) there corresponds one and only one point in the plane; and to each point in the plane there corresponds but one such symbol. Here again, we may speak of the “point (x, y) ,” meaning the “ordered number pair x and y .” This convenient language can be used when we have a rectangular coordinate system in a space of three or more dimensions. Thus the “point (x_1, x_2, \dots, x_n) ” means the numbers x_1, x_2, \dots, x_n in the order stated. Accordingly, in describing our sets, we frequently speak of a set of points (a set whose elements are points), being careful, of course, to describe the set so as to avoid any ambiguity. The notation $C = \{x : 0 \leq x \leq 1\}$ is read “ C is the one-dimensional set of points x for which $0 \leq x \leq 1$.” Similarly, $C = \{(x, y) : 0 \leq x \leq 1, 0 \leq y \leq 1\}$ can be read “ C is the two-dimensional set of points (x, y) that are interior to, or on the boundary of, a square with opposite vertices at $(0, 0)$ and $(1, 1)$.”

We say a set C is **countable** if C is finite or has as many elements as there are positive integers. For example, the sets $C_1 = \{1, 2, \dots, 100\}$ and $C_2 = \{1, 3, 5, 7, \dots\}$

are countable sets. The interval of real numbers $(0, 1]$, though, is not countable.

1.2.1 Review of Set Theory

As in Section 1.1, let \mathcal{C} denote the sample space for the experiment. Recall that events are subsets of \mathcal{C} . We use the words event and subset interchangeably in this section. An elementary algebra of sets will prove quite useful for our purposes. We now review this algebra below along with illustrative examples. For illustration, we also make use of **Venn diagrams**. Consider the collection of Venn diagrams in Figure 1.2.1. The interior of the rectangle in each plot represents the sample space \mathcal{C} . The shaded region in Panel (a) represents the event A .

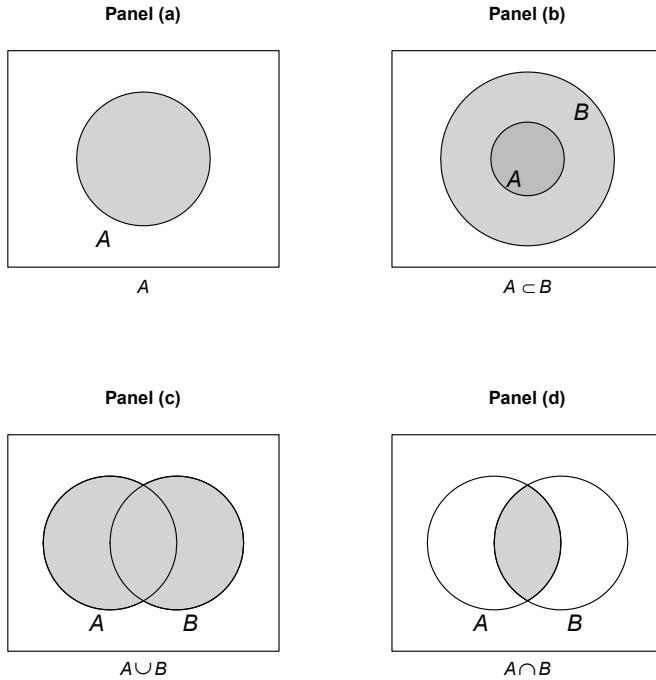

Figure 1.2.1: A series of Venn diagrams. The sample space \mathcal{C} is represented by the interior of the rectangle in each plot. Panel (a) depicts the event A ; Panel (b) depicts $A \subset B$; Panel (c) depicts $A \cup B$; and Panel (d) depicts $A \cap B$.

We first define the complement of an event A .

Definition 1.2.1. *The complement of an event A is the set of all elements in \mathcal{C} which are not in A . We denote the complement of A by A^c . That is, $A^c = \{x \in \mathcal{C} : x \notin A\}$.*

The complement of A is represented by the white space in the Venn diagram in Panel (a) of Figure 1.2.1.

The empty set is the event with no elements in it. It is denoted by ϕ . Note that $C^c = \phi$ and $\phi^c = C$. The next definition defines when one event is a subset of another.

Definition 1.2.2. *If each element of a set A is also an element of set B , the set A is called a **subset** of the set B . This is indicated by writing $A \subset B$. If $A \subset B$ and also $B \subset A$, the two sets have the same elements, and this is indicated by writing $A = B$.*

Panel (b) of Figure 1.2.1 depicts $A \subset B$.

The event A or B is defined as follows:

Definition 1.2.3. *Let A and B be events. Then the **union** of A and B is the set of all elements that are in A or in B or in both A and B . The union of A and B is denoted by $A \cup B$*

Panel (c) of Figure 1.2.1 shows $A \cup B$.

The event that both A and B occur is defined by,

Definition 1.2.4. *Let A and B be events. Then the **intersection** of A and B is the set of all elements that are in both A and B . The intersection of A and B is denoted by $A \cap B$*

Panel (d) of Figure 1.2.1 illustrates $A \cap B$.

Two events are **disjoint** if they have no elements in common. More formally we define

Definition 1.2.5. *Let A and B be events. Then A and B are **disjoint** if $A \cap B = \phi$*

If A and B are disjoint, then we say $A \cup B$ forms a **disjoint union**. The next two examples illustrate these concepts.

Example 1.2.1. Suppose we have a spinner with the numbers 1 through 10 on it. The experiment is to spin the spinner and record the number spun. Then $C = \{1, 2, \dots, 10\}$. Define the events A , B , and C by $A = \{1, 2\}$, $B = \{2, 3, 4\}$, and $C = \{3, 4, 5, 6\}$, respectively.

$$\begin{aligned} A^c &= \{3, 4, \dots, 10\}; & A \cup B &= \{1, 2, 3, 4\}; & A \cap B &= \{2\} \\ A \cap C &= \phi; & B \cap C &= \{3, 4\}; & B \cap C &\subset B; & B \cap C &\subset C \\ A \cup (B \cap C) &= \{1, 2\} \cup \{3, 4\} = \{1, 2, 3, 4\} & (1.2.1) \\ (A \cup B) \cap (A \cup C) &= \{1, 2, 3, 4\} \cap \{1, 2, 3, 4, 5, 6\} = \{1, 2, 3, 4\} & (1.2.2) \end{aligned}$$

The reader should verify these results. ■

Example 1.2.2. For this example, suppose the experiment is to select a real number in the open interval $(0, 5)$; hence, the sample space is $C = (0, 5)$. Let $A = (1, 3)$,

$B = (2, 4)$, and $C = [3, 4.5)$.

$$A \cup B = (1, 4); \quad A \cap B = (2, 3); \quad B \cap C = [3, 4) \quad (1.2.3)$$

$$A \cap (B \cup C) = (1, 3) \cap (2, 4.5) = (2, 3) \quad (1.2.4)$$

$$(A \cap B) \cup (A \cap C) = (2, 3) \cup \emptyset = (2, 3) \quad (1.2.4)$$

A sketch of the real number line between 0 and 5 helps to verify these results. ■

Expressions (1.2.1)–(1.2.2) and (1.2.3)–(1.2.4) are illustrations of general **distributive laws**. For any sets A , B , and C ,

$$\begin{aligned} A \cap (B \cup C) &= (A \cap B) \cup (A \cap C) \\ A \cup (B \cap C) &= (A \cup B) \cap (A \cup C). \end{aligned} \quad (1.2.5)$$

These follow directly from set theory. To verify each identity, sketch Venn diagrams of both sides.

The next two identities are collectively known as **DeMorgan's Laws**. For any sets A and B ,

$$(A \cap B)^c = A^c \cup B^c \quad (1.2.6)$$

$$(A \cup B)^c = A^c \cap B^c. \quad (1.2.7)$$

For instance, in Example 1.2.1,

$$(A \cup B)^c = \{1, 2, 3, 4\}^c = \{5, 6, \dots, 10\} = \{3, 4, \dots, 10\} \cap \{1, 5, 6, \dots, 10\} = A^c \cap B^c;$$

while, from Example 1.2.2,

$$(A \cap B)^c = (2, 3)^c = (0, 2] \cup [3, 5) = [(0, 1] \cup [3, 5)] \cup [(0, 2] \cup [4, 5)] = A^c \cup B^c.$$

As the last expression suggests, it is easy to extend unions and intersections to more than two sets. If A_1, A_2, \dots, A_n are any sets, we define

$$A_1 \cup A_2 \cup \dots \cup A_n = \{x : x \in A_i, \text{ for some } i = 1, 2, \dots, n\} \quad (1.2.8)$$

$$A_1 \cap A_2 \cap \dots \cap A_n = \{x : x \in A_i, \text{ for all } i = 1, 2, \dots, n\}. \quad (1.2.9)$$

We often abbreviate these by $\cup_{i=1}^n A_i$ and $\cap_{i=1}^n A_i$, respectively. Expressions for countable unions and intersections follow directly; that is, if $A_1, A_2, \dots, A_n \dots$ is a sequence of sets then

$$A_1 \cup A_2 \cup \dots = \{x : x \in A_n, \text{ for some } n = 1, 2, \dots\} = \cup_{n=1}^{\infty} A_n \quad (1.2.10)$$

$$A_1 \cap A_2 \cap \dots = \{x : x \in A_n, \text{ for all } n = 1, 2, \dots\} = \cap_{n=1}^{\infty} A_n. \quad (1.2.11)$$

The next two examples illustrate these ideas.

Example 1.2.3. Suppose $\mathcal{C} = \{1, 2, 3, \dots\}$. If $A_n = \{1, 3, \dots, 2n - 1\}$ and $B_n = \{n, n + 1, \dots\}$, for $n = 1, 2, 3, \dots$, then

$$\cup_{n=1}^{\infty} A_n = \{1, 3, 5, \dots\}; \quad \cap_{n=1}^{\infty} A_n = \{1\}; \quad (1.2.12)$$

$$\cup_{n=1}^{\infty} B_n = \mathcal{C}; \quad \cap_{n=1}^{\infty} B_n = \emptyset. \quad \blacksquare \quad (1.2.13)$$

Example 1.2.4. Suppose \mathcal{C} is the interval of real numbers $(0, 5)$. Suppose $C_n = (1 - n^{-1}, 2 + n^{-1})$ and $D_n = (n^{-1}, 3 - n^{-1})$, for $n = 1, 2, 3, \dots$. Then

$$\cup_{n=1}^{\infty} C_n = (0, 3); \quad \cap_{n=1}^{\infty} C_n = [1, 2] \quad (1.2.14)$$

$$\cup_{n=1}^{\infty} D_n = (0, 3); \quad \cap_{n=1}^{\infty} D_n = (1, 2). \blacksquare \quad (1.2.15)$$

We occasionally have sequences of sets that are **monotone**. They are of two types. We say a sequence of sets $\{A_n\}$ is **nondecreasing**, (**nested upward**), if $A_n \subset A_{n+1}$ for $n = 1, 2, 3, \dots$. For such a sequence, we define

$$\lim_{n \rightarrow \infty} A_n = \cup_{n=1}^{\infty} A_n. \quad (1.2.16)$$

The sequence of sets $A_n = \{1, 3, \dots, 2n - 1\}$ of Example 1.2.3 is such a sequence. So in this case, we write $\lim_{n \rightarrow \infty} A_n = \{1, 3, 5, \dots\}$. The sequence of sets $\{D_n\}$ of Example 1.2.4 is also a nondecreasing sequence of sets.

The second type of monotone sets consists of the **nonincreasing**, (**nested downward**) sequences. A sequence of sets $\{A_n\}$ is **nonincreasing**, if $A_n \supset A_{n+1}$ for $n = 1, 2, 3, \dots$. In this case, we define

$$\lim_{n \rightarrow \infty} A_n = \cap_{n=1}^{\infty} A_n. \quad (1.2.17)$$

The sequences of sets $\{B_n\}$ and $\{C_n\}$ of Examples 1.2.3 and 1.2.4, respectively, are examples of nonincreasing sequences of sets.

1.2.2 Set Functions

Many of the functions used in calculus and in this book are functions that map real numbers into real numbers. We are concerned also with functions that map sets into real numbers. Such functions are naturally called functions of a set or, more simply, **set functions**. Next we give some examples of set functions and evaluate them for certain simple sets.

Example 1.2.5. Let $\mathcal{C} = R$, the set of real numbers. For a subset A in \mathcal{C} , let $Q(A)$ be equal to the number of points in A that correspond to positive integers. Then $Q(A)$ is a set function of the set A . Thus, if $A = \{x : 0 < x < 5\}$, then $Q(A) = 4$; if $A = \{-2, -1\}$, then $Q(A) = 0$; and if $A = \{x : -\infty < x < 6\}$, then $Q(A) = 5$. ■

Example 1.2.6. Let $\mathcal{C} = R^2$. For a subset A of \mathcal{C} , let $Q(A)$ be the area of A if A has a finite area; otherwise, let $Q(A)$ be undefined. Thus, if $A = \{(x, y) : x^2 + y^2 \leq 1\}$, then $Q(A) = \pi$; if $A = \{(0, 0), (1, 1), (0, 1)\}$, then $Q(A) = 0$; and if $A = \{(x, y) : 0 \leq x, 0 \leq y, x + y \leq 1\}$, then $Q(A) = \frac{1}{2}$. ■

Often our set functions are defined in terms of sums or integrals.¹ With this in mind, we introduce the following notation. The symbol

$$\int_A f(x) dx$$

¹Please see Chapters 2 and 3 of *Mathematical Comments*, at site noted in the Preface, for a review of sums and integrals

means the ordinary (Riemann) integral of $f(x)$ over a prescribed one-dimensional set A and the symbol

$$\iint_A g(x, y) dx dy$$

means the Riemann integral of $g(x, y)$ over a prescribed two-dimensional set A . This notation can be extended to integrals over n dimensions. To be sure, unless these sets A and these functions $f(x)$ and $g(x, y)$ are chosen with care, the integrals frequently fail to exist. Similarly, the symbol

$$\sum_A f(x)$$

means the sum extended over all $x \in A$ and the symbol

$$\sum_A \sum g(x, y)$$

means the sum extended over all $(x, y) \in A$. As with integration, this notation extends to sums over n dimensions.

The first example is for a set function defined on sums involving a **geometric series**. As pointed out in Example 2.3.1 of *Mathematical Comments*,² if $|a| < 1$, then the following series converges to $1/(1 - a)$:

$$\sum_{n=0}^{\infty} a^n = \frac{1}{1-a}, \quad \text{if } |a| < 1. \quad (1.2.18)$$

Example 1.2.7. Let \mathcal{C} be the set of all nonnegative integers and let A be a subset of \mathcal{C} . Define the set function Q by

$$Q(A) = \sum_{n \in A} \left(\frac{2}{3}\right)^n. \quad (1.2.19)$$

It follows from (1.2.18) that $Q(\mathcal{C}) = 3$. If $A = \{1, 2, 3\}$ then $Q(A) = 38/27$. Suppose $B = \{1, 3, 5, \dots\}$ is the set of all odd positive integers. The computation of $Q(B)$ is given next. This derivation consists of rewriting the series so that (1.2.18) can be applied. Frequently, we perform such derivations in this book.

$$\begin{aligned} Q(B) &= \sum_{n \in B} \left(\frac{2}{3}\right)^n = \sum_{n=0}^{\infty} \left(\frac{2}{3}\right)^{2n+1} \\ &= \frac{2}{3} \sum_{n=0}^{\infty} \left[\left(\frac{2}{3}\right)^2\right]^n = \frac{2}{3} \frac{1}{1 - (4/9)} = \frac{6}{5} \blacksquare \end{aligned}$$

In the next example, the set function is defined in terms of an integral involving the exponential function $f(x) = e^{-x}$.

²Downloadable at site noted in the Preface

Example 1.2.8. Let \mathcal{C} be the interval of positive real numbers, i.e., $\mathcal{C} = (0, \infty)$. Let A be a subset of \mathcal{C} . Define the set function Q by

$$Q(A) = \int_A e^{-x} dx, \quad (1.2.20)$$

provided the integral exists. The reader should work through the following integrations:

$$\begin{aligned} Q[(1, 3)] &= \int_1^3 e^{-x} dx = -e^{-x} \Big|_1^3 = e^{-1} - e^{-3} \doteq 0.318 \\ Q[(5, \infty)] &= \int_1^3 e^{-x} dx = -e^{-x} \Big|_5^\infty = e^{-5} \doteq 0.007 \\ Q[(1, 3) \cup [3, 5]] &= \int_1^5 e^{-x} dx = \int_1^3 e^{-x} dx + \int_3^5 e^{-x} dx = Q[(1, 3)] + Q([3, 5]) \\ Q(\mathcal{C}) &= \int_0^\infty e^{-x} dx = 1. \quad \blacksquare \end{aligned}$$

Our final example, involves an n dimensional integral.

Example 1.2.9. Let $\mathcal{C} = R^n$. For A in \mathcal{C} define the set function

$$Q(A) = \int_A \cdots \int dx_1 dx_2 \cdots dx_n,$$

provided the integral exists. For example, if $A = \{(x_1, x_2, \dots, x_n) : 0 \leq x_1 \leq x_2, 0 \leq x_i \leq 1, \text{ for } i = 3, 4, \dots, n\}$, then upon expressing the multiple integral as an iterated integral³ we obtain

$$\begin{aligned} Q(A) &= \int_0^1 \left[\int_0^{x_2} dx_1 \right] dx_2 \bullet \prod_{i=3}^n \left[\int_0^1 dx_i \right] \\ &= \frac{x_2^2}{2} \Big|_0^1 \bullet 1 = \frac{1}{2}. \end{aligned}$$

If $B = \{(x_1, x_2, \dots, x_n) : 0 \leq x_1 \leq x_2 \leq \cdots \leq x_n \leq 1\}$, then

$$\begin{aligned} Q(B) &= \int_0^1 \left[\int_0^{x_n} \cdots \left[\int_0^{x_3} \left[\int_0^{x_2} dx_1 \right] dx_2 \right] \cdots dx_{n-1} \right] dx_n \\ &= \frac{1}{n!}, \end{aligned}$$

where $n! = n(n-1) \cdots 3 \cdot 2 \cdot 1$. \blacksquare

³For a discussion of multiple integrals in terms of iterated integrals, see Chapter 3 of *Mathematical Comments*.

EXERCISES

1.2.1. Find the union $C_1 \cup C_2$ and the intersection $C_1 \cap C_2$ of the two sets C_1 and C_2 , where

- (a) $C_1 = \{0, 1, 2\}$, $C_2 = \{2, 3, 4\}$.
- (b) $C_1 = \{x : 0 < x < 2\}$, $C_2 = \{x : 1 \leq x < 3\}$.
- (c) $C_1 = \{(x, y) : 0 < x < 2, 1 < y < 2\}$, $C_2 = \{(x, y) : 1 < x < 3, 1 < y < 3\}$.

1.2.2. Find the complement C^c of the set C with respect to the space \mathcal{C} if

- (a) $\mathcal{C} = \{x : 0 < x < 1\}$, $C = \{x : \frac{5}{8} < x < 1\}$.
- (b) $\mathcal{C} = \{(x, y, z) : x^2 + y^2 + z^2 \leq 1\}$, $C = \{(x, y, z) : x^2 + y^2 + z^2 = 1\}$.
- (c) $\mathcal{C} = \{(x, y) : |x| + |y| \leq 2\}$, $C = \{(x, y) : x^2 + y^2 < 2\}$.

1.2.3. List all possible arrangements of the four letters m, a, r , and y . Let C_1 be the collection of the arrangements in which y is in the last position. Let C_2 be the collection of the arrangements in which m is in the first position. Find the union and the intersection of C_1 and C_2 .

1.2.4. Concerning DeMorgan's Laws (1.2.6) and (1.2.7):

- (a) Use Venn diagrams to verify the laws.
- (b) Show that the laws are true.
- (c) Generalize the laws to countable unions and intersections.

1.2.5. By the use of Venn diagrams, in which the space \mathcal{C} is the set of points enclosed by a rectangle containing the circles C_1, C_2 , and C_3 , compare the following sets. These laws are called the **distributive laws**.

- (a) $C_1 \cap (C_2 \cup C_3)$ and $(C_1 \cap C_2) \cup (C_1 \cap C_3)$.
- (b) $C_1 \cup (C_2 \cap C_3)$ and $(C_1 \cup C_2) \cap (C_1 \cup C_3)$.

1.2.6. Show that the following sequences of sets, $\{C_k\}$, are nondecreasing, (1.2.16), then find $\lim_{k \rightarrow \infty} C_k$.

- (a) $C_k = \{x : 1/k \leq x \leq 3 - 1/k\}$, $k = 1, 2, 3, \dots$
- (b) $C_k = \{(x, y) : 1/k \leq x^2 + y^2 \leq 4 - 1/k\}$, $k = 1, 2, 3, \dots$

1.2.7. Show that the following sequences of sets, $\{C_k\}$, are nonincreasing, (1.2.17), then find $\lim_{k \rightarrow \infty} C_k$.

- (a) $C_k = \{x : 2 - 1/k < x \leq 2\}$, $k = 1, 2, 3, \dots$
- (b) $C_k = \{x : 2 < x \leq 2 + 1/k\}$, $k = 1, 2, 3, \dots$

- (c) $C_k = \{(x, y) : 0 \leq x^2 + y^2 \leq 1/k\}$, $k = 1, 2, 3, \dots$

1.2.8. For every one-dimensional set C , define the function $Q(C) = \sum_C f(x)$, where $f(x) = (\frac{2}{3})(\frac{1}{3})^x$, $x = 0, 1, 2, \dots$, zero elsewhere. If $C_1 = \{x : x = 0, 1, 2, 3\}$ and $C_2 = \{x : x = 0, 1, 2, \dots\}$, find $Q(C_1)$ and $Q(C_2)$.

Hint: Recall that $S_n = a + ar + \dots + ar^{n-1} = a(1 - r^n)/(1 - r)$ and, hence, it follows that $\lim_{n \rightarrow \infty} S_n = a/(1 - r)$ provided that $|r| < 1$.

1.2.9. For every one-dimensional set C for which the integral exists, let $Q(C) = \int_C f(x) dx$, where $f(x) = 6x(1 - x)$, $0 < x < 1$, zero elsewhere; otherwise, let $Q(C)$ be undefined. If $C_1 = \{x : \frac{1}{4} < x < \frac{3}{4}\}$, $C_2 = \{\frac{1}{2}\}$, and $C_3 = \{x : 0 < x < 10\}$, find $Q(C_1)$, $Q(C_2)$, and $Q(C_3)$.

1.2.10. For every two-dimensional set C contained in R^2 for which the integral exists, let $Q(C) = \int \int_C (x^2 + y^2) dxdy$. If $C_1 = \{(x, y) : -1 \leq x \leq 1, -1 \leq y \leq 1\}$, $C_2 = \{(x, y) : -1 \leq x = y \leq 1\}$, and $C_3 = \{(x, y) : x^2 + y^2 \leq 1\}$, find $Q(C_1)$, $Q(C_2)$, and $Q(C_3)$.

1.2.11. Let \mathcal{C} denote the set of points that are interior to, or on the boundary of, a square with opposite vertices at the points $(0, 0)$ and $(1, 1)$. Let $Q(C) = \int \int_C dy dx$.

- (a) If $C \subset \mathcal{C}$ is the set $\{(x, y) : 0 < x < y < 1\}$, compute $Q(C)$.
- (b) If $C \subset \mathcal{C}$ is the set $\{(x, y) : 0 < x = y < 1\}$, compute $Q(C)$.
- (c) If $C \subset \mathcal{C}$ is the set $\{(x, y) : 0 < x/2 \leq y \leq 3x/2 < 1\}$, compute $Q(C)$.

1.2.12. Let \mathcal{C} be the set of points interior to or on the boundary of a cube with edge of length 1. Moreover, say that the cube is in the first octant with one vertex at the point $(0, 0, 0)$ and an opposite vertex at the point $(1, 1, 1)$. Let $Q(C) = \int \int \int_C dxdydz$.

- (a) If $C \subset \mathcal{C}$ is the set $\{(x, y, z) : 0 < x < y < z < 1\}$, compute $Q(C)$.
- (b) If C is the subset $\{(x, y, z) : 0 < x = y = z < 1\}$, compute $Q(C)$.

1.2.13. Let C denote the set $\{(x, y, z) : x^2 + y^2 + z^2 \leq 1\}$. Using spherical coordinates, evaluate

$$Q(C) = \int \int \int_C \sqrt{x^2 + y^2 + z^2} dxdydz.$$

1.2.14. To join a certain club, a person must be either a statistician or a mathematician or both. Of the 25 members in this club, 19 are statisticians and 16 are mathematicians. How many persons in the club are both a statistician and a mathematician?

1.2.15. After a hard-fought football game, it was reported that, of the 11 starting players, 8 hurt a hip, 6 hurt an arm, 5 hurt a knee, 3 hurt both a hip and an arm, 2 hurt both a hip and a knee, 1 hurt both an arm and a knee, and no one hurt all three. Comment on the accuracy of the report.

1.3 The Probability Set Function

Given an experiment, let \mathcal{C} denote the sample space of all possible outcomes. As discussed in Section 1.1, we are interested in assigning probabilities to events, i.e., subsets of \mathcal{C} . What should be our collection of events? If \mathcal{C} is a finite set, then we could take the set of all subsets as this collection. For infinite sample spaces, though, with assignment of probabilities in mind, this poses mathematical technicalities that are better left to a course in probability theory. We assume that in all cases, the collection of events is sufficiently rich to include all possible events of interest and is closed under complements and countable unions of these events. Using DeMorgan's Laws, (1.2.6)–(1.2.7), the collection is then also closed under countable intersections. We denote this collection of events by \mathcal{B} . Technically, such a collection of events is called a **σ -field** of subsets.

Now that we have a sample space, \mathcal{C} , and our collection of events, \mathcal{B} , we can define the third component in our probability space, namely a probability set function. In order to motivate its definition, we consider the relative frequency approach to probability.

Remark 1.3.1. The definition of probability consists of three axioms which we motivate by the following three intuitive properties of relative frequency. Let \mathcal{C} be a sample space and let $A \subset \mathcal{C}$. Suppose we repeat the experiment N times. Then the relative frequency of A is $f_A = \#\{A\}/N$, where $\#\{A\}$ denotes the number of times A occurred in the N repetitions. Note that $f_A \geq 0$ and $f_{\mathcal{C}} = 1$. These are the first two properties. For the third, suppose that A_1 and A_2 are disjoint events. Then $f_{A_1 \cup A_2} = f_{A_1} + f_{A_2}$. These three properties of relative frequencies form the axioms of a probability, except that the third axiom is in terms of countable unions. As with the axioms of probability, the readers should check that the theorems we prove below about probabilities agree with their intuition of relative frequency. ■

Definition 1.3.1 (Probability). Let \mathcal{C} be a sample space and let \mathcal{B} be the set of events. Let P be a real-valued function defined on \mathcal{B} . Then P is a **probability set function** if P satisfies the following three conditions:

1. $P(A) \geq 0$, for all $A \in \mathcal{B}$.
2. $P(\mathcal{C}) = 1$.
3. If $\{A_n\}$ is a sequence of events in \mathcal{B} and $A_m \cap A_n = \emptyset$ for all $m \neq n$, then

$$P\left(\bigcup_{n=1}^{\infty} A_n\right) = \sum_{n=1}^{\infty} P(A_n).$$

A collection of events whose members are pairwise disjoint, as in (3), is said to be a **mutually exclusive** collection and its union is often referred to as a **disjoint union**. The collection is further said to be **exhaustive** if the union of its events is the sample space, in which case $\sum_{n=1}^{\infty} P(A_n) = 1$. We often say that a mutually exclusive and exhaustive collection of events forms a **partition** of \mathcal{C} .

A probability set function tells us how the probability is distributed over the set of events, \mathcal{B} . In this sense we speak of a distribution of probability. We often drop the word “set” and refer to P as a probability function.

The following theorems give us some other properties of a probability set function. In the statement of each of these theorems, $P(A)$ is taken, tacitly, to be a probability set function defined on the collection of events \mathcal{B} of a sample space \mathcal{C} .

Theorem 1.3.1. *For each event $A \in \mathcal{B}$, $P(A) = 1 - P(A^c)$.*

Proof: We have $\mathcal{C} = A \cup A^c$ and $A \cap A^c = \phi$. Thus, from (2) and (3) of Definition 1.3.1, it follows that

$$1 = P(\mathcal{C}) = P(A) + P(A^c),$$

which is the desired result. ■

Theorem 1.3.2. *The probability of the null set is zero; that is, $P(\phi) = 0$.*

Proof: In Theorem 1.3.1, take $A = \phi$ so that $A^c = \mathcal{C}$. Accordingly, we have

$$P(\phi) = 1 - P(\mathcal{C}) = 1 - 1 = 0$$

and the theorem is proved. ■

Theorem 1.3.3. *If A and B are events such that $A \subset B$, then $P(A) \leq P(B)$.*

Proof: Now $B = A \cup (A^c \cap B)$ and $A \cap (A^c \cap B) = \phi$. Hence, from (3) of Definition 1.3.1,

$$P(B) = P(A) + P(A^c \cap B).$$

From (1) of Definition 1.3.1, $P(A^c \cap B) \geq 0$. Hence, $P(B) \geq P(A)$. ■

Theorem 1.3.4. *For each $A \in \mathcal{B}$, $0 \leq P(A) \leq 1$.*

Proof: Since $\phi \subset A \subset \mathcal{C}$, we have by Theorem 1.3.3 that

$$P(\phi) \leq P(A) \leq P(\mathcal{C}) \quad \text{or} \quad 0 \leq P(A) \leq 1,$$

the desired result. ■

Part (3) of the definition of probability says that $P(A \cup B) = P(A) + P(B)$ if A and B are disjoint, i.e., $A \cap B = \phi$. The next theorem gives the rule for any two events regardless if they are disjoint or not.

Theorem 1.3.5. *If A and B are events in \mathcal{C} , then*

$$P(A \cup B) = P(A) + P(B) - P(A \cap B).$$

Proof: Each of the sets $A \cup B$ and B can be represented, respectively, as a union of nonintersecting sets as follows:

$$A \cup B = A \cup (A^c \cap B) \quad \text{and} \quad B = (A \cap B) \cup (A^c \cap B). \quad (1.3.1)$$

That these identities hold for all sets A and B follows from set theory. Also, the Venn diagrams of Figure 1.3.1 offer a verification of them.

Thus, from (3) of Definition 1.3.1,

$$P(A \cup B) = P(A) + P(A^c \cap B)$$

and

$$P(B) = P(A \cap B) + P(A^c \cap B).$$

If the second of these equations is solved for $P(A^c \cap B)$ and this result is substituted in the first equation, we obtain

$$P(A \cup B) = P(A) + P(B) - P(A \cap B).$$

This completes the proof. ■

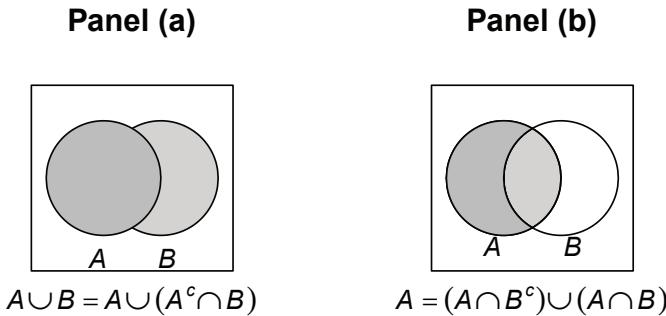

Figure 1.3.1: Venn diagrams depicting the two disjoint unions given in expression (1.3.1). Panel (a) depicts the first disjoint union while Panel (b) shows the second disjoint union.

Example 1.3.1. Let \mathcal{C} denote the sample space of Example 1.1.2. Let the probability set function assign a probability of $\frac{1}{36}$ to each of the 36 points in \mathcal{C} ; that is, the dice are fair. If $C_1 = \{(1, 1), (2, 1), (3, 1), (4, 1), (5, 1)\}$ and $C_2 = \{(1, 2), (2, 2), (3, 2)\}$, then $P(C_1) = \frac{5}{36}$, $P(C_2) = \frac{3}{36}$, $P(C_1 \cup C_2) = \frac{8}{36}$, and $P(C_1 \cap C_2) = 0$. ■

Example 1.3.2. Two coins are to be tossed and the outcome is the ordered pair (face on the first coin, face on the second coin). Thus the sample space may be represented as $\mathcal{C} = \{(H, H), (H, T), (T, H), (T, T)\}$. Let the probability set function assign a probability of $\frac{1}{4}$ to each element of \mathcal{C} . Let $C_1 = \{(H, H), (H, T)\}$ and $C_2 = \{(H, H), (T, H)\}$. Then $P(C_1) = P(C_2) = \frac{1}{2}$, $P(C_1 \cap C_2) = \frac{1}{4}$, and, in accordance with Theorem 1.3.5, $P(C_1 \cup C_2) = \frac{1}{2} + \frac{1}{2} - \frac{1}{4} = \frac{3}{4}$. ■

For a finite sample space, we can generate probabilities as follows. Let $\mathcal{C} = \{x_1, x_2, \dots, x_m\}$ be a finite set of m elements. Let p_1, p_2, \dots, p_m be fractions such that

$$0 \leq p_i \leq 1 \text{ for } i = 1, 2, \dots, m \text{ and } \sum_{i=1}^m p_i = 1. \quad (1.3.2)$$

Suppose we define P by

$$P(A) = \sum_{x_i \in A} p_i, \quad \text{for all subsets } A \text{ of } \mathcal{C}. \quad (1.3.3)$$

Then $P(A) \geq 0$ and $P(\mathcal{C}) = 1$. Further, it follows that $P(A \cup B) = P(A) + P(B)$ when $A \cap B = \emptyset$. Therefore, P is a probability on \mathcal{C} . For illustration, each of the following four assignments forms a probability on $\mathcal{C} = \{1, 2, \dots, 6\}$. For each, we also compute $P(A)$ for the event $A = \{1, 6\}$.

$$p_1 = p_2 = \dots = p_6 = \frac{1}{6}; \quad P(A) = \frac{1}{3}. \quad (1.3.4)$$

$$p_1 = p_2 = 0.1, p_3 = p_4 = p_5 = p_6 = 0.2; \quad P(A) = 0.3.$$

$$p_i = \frac{i}{21}, \quad i = 1, 2, \dots, 6; \quad P(A) = \frac{7}{21}.$$

$$p_1 = \frac{3}{\pi}, p_2 = 1 - \frac{3}{\pi}, p_3 = p_4 = p_5 = p_6 = 0.0; \quad P(A) = \frac{3}{\pi}.$$

Note that the individual probabilities for the first probability set function, (1.3.4), are the same. This is an example of the equilikely case which we now formally define.

Definition 1.3.2 (Equilikely Case). *Let $\mathcal{C} = \{x_1, x_2, \dots, x_m\}$ be a finite sample space. Let $p_i = 1/m$ for all $i = 1, 2, \dots, m$ and for all subsets A of \mathcal{C} define*

$$P(A) = \sum_{x_i \in A} \frac{1}{m} = \frac{\#(A)}{m},$$

where $\#(A)$ denotes the number of elements in A . Then P is a probability on \mathcal{C} and it is referred to as the **equilikely case**. ■

Equilikely cases are frequently probability models of interest. Examples include: the flip of a fair coin; five cards drawn from a well shuffled deck of 52 cards; a spin of a fair spinner with the numbers 1 through 36 on it; and the upfaces of the roll of a pair of balanced dice. For each of these experiments, as stated in the definition, we only need to know the number of elements in an event to compute the probability of that event. For example, a card player may be interested in the probability of getting a pair (two of a kind) in a hand of five cards dealt from a well shuffled deck of 52 cards. To compute this probability, we need to know the number of five card hands and the number of such hands which contain a pair. Because the equilikely case is often of interest, we next develop some counting rules which can be used to compute the probabilities of events of interest.

1.3.1 Counting Rules

We discuss three counting rules that are usually discussed in an elementary algebra course.

The first rule is called the **mn -rule** (m times n -rule), which is also called the **multiplication rule**. Let $A = \{x_1, x_2, \dots, x_m\}$ be a set of m elements and let $B = \{y_1, y_2, \dots, y_n\}$ be a set of n elements. Then there are mn ordered pairs, (x_i, y_j) , $i = 1, 2, \dots, m$ and $j = 1, 2, \dots, n$, of elements, the first from A and the second from B . Informally, we often speak of ways, here. For example there are five roads (ways) between cities I and II and there are ten roads (ways) between cities II and III. Hence, there are $5 * 10 = 50$ ways to get from city I to city III by going from city I to city II and then from city II to city III. This rule extends immediately to more than two sets. For instance, suppose in a certain state that driver license plates have the pattern of three letters followed by three numbers. Then there are $26^3 * 10^3$ possible license plates in this state.

Next, let A be a set with n elements. Suppose we are interested in k -tuples whose components are elements of A . Then by the extended mn rule, there are $n \cdot n \cdots n = n^k$ such k -tuples whose components are elements of A . Next, suppose $k \leq n$ and we are interested in k -tuples whose components are distinct (no repeats) elements of A . There are n elements from which to choose for the first component, $n - 1$ for the second component, \dots , $n - (k - 1)$ for the k th. Hence, by the mn rule, there are $n(n - 1) \cdots (n - (k - 1))$ such k -tuples with distinct elements. We call each such k -tuple a **permutation** and use the symbol P_k^n to denote the number of k permutations taken from a set of n elements. This number of permutations, P_k^n is our second counting rule. We can rewrite it as

$$P_k^n = n(n - 1) \cdots (n - (k - 1)) = \frac{n!}{(n - k)!}. \quad (1.3.5)$$

Example 1.3.3 (Birthday Problem). Suppose there are n people in a room. Assume that $n < 365$ and that the people are unrelated in any way. Find the probability of the event A that at least 2 people have the same birthday. For convenience, assign the numbers 1 through n to the people in the room. Then use n -tuples to denote the birthdays of the first person through the n th person in the room. Using the mn -rule, there are 365^n possible birthday n -tuples for these n people. This is the number of elements in the sample space. Now assume that birthdays are equilike to occur on any of the 365 days. Hence, each of these n -tuples has probability 365^{-n} . Notice that the complement of A is the event that all the birthdays in the room are distinct; that is, the number of n -tuples in A^c is P_n^{365} . Thus, the probability of A is

$$P(A) = 1 - \frac{P_n^{365}}{365^n}.$$

For instance, if $n = 2$ then $P(A) = 1 - (365 * 364)/(365^2) = 0.0027$. This formula is not easy to compute by hand. The following R function⁴ computes the $P(A)$ for the input n and it can be downloaded at the sites mentioned in the Preface.

⁴An R primer for the course is found in Appendix B.

```
bday = function(n){ bday = 1; nm1 = n - 1
  for(j in 1:nm1){bday = bday*((365-j)/365)}
  bday <- 1 - bday; return(bday)}
```

Assuming that the file `bday.R` contains this function, here is the R segment computing $P(A)$ for $n = 10$:

```
> source("bday.R")
> bday(10)
[1] 0.1169482
```

■ For our last counting rule, as with permutations, we are drawing from a set A of n elements. Now, suppose order is not important, so instead of counting the number of permutations we want to count the number of subsets of k elements taken from A . We use the symbol $\binom{n}{k}$ to denote the total number of these subsets. Consider a subset of k elements from A . By the permutation rule it generates $P_k^k = k(k-1)\cdots 1 = k!$ permutations. Furthermore, all these permutations are distinct from the permutations generated by other subsets of k elements from A . Finally, each permutation of k distinct elements drawn from A must be generated by one of these subsets. Hence, we have shown that $P_k^n = \binom{n}{k}k!$; that is,

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}. \quad (1.3.6)$$

We often use the terminology combinations instead of subsets. So we say that there are $\binom{n}{k}$ **combinations** of k things taken from a set of n things. Another common symbol for $\binom{n}{k}$ is C_k^n .

It is interesting to note that if we expand the binomial series,

$$(a+b)^n = (a+b)(a+b)\cdots(a+b),$$

we get

$$(a+b)^n = \sum_{k=0}^n \binom{n}{k} a^k b^{n-k}, \quad (1.3.7)$$

because we can select the k factors from which to take a in $\binom{n}{k}$ ways. So $\binom{n}{k}$ is also referred to as a **binomial coefficient**.

Example 1.3.4 (Poker Hands). Let a card be drawn at random from an ordinary deck of 52 playing cards that has been well shuffled. The sample space \mathcal{C} consists of 52 elements, each element represents one and only one of the 52 cards. Because the deck has been well shuffled, it is reasonable to assume that each of these outcomes has the same probability $\frac{1}{52}$. Accordingly, if E_1 is the set of outcomes that are spades, $P(E_1) = \frac{13}{52} = \frac{1}{4}$ because there are 13 spades in the deck; that is, $\frac{1}{4}$ is the probability of drawing a card that is a spade. If E_2 is the set of outcomes that are kings, $P(E_2) = \frac{4}{52} = \frac{1}{13}$ because there are 4 kings in the deck; that is, $\frac{1}{13}$ is the probability of drawing a card that is a king. These computations are very easy

because there are no difficulties in the determination of the number of elements in each event.

However, instead of drawing only one card, suppose that five cards are taken, at random and without replacement, from this deck; i.e., a five card poker hand. In this instance, order is not important. So a hand is a subset of five elements drawn from a set of 52 elements. Hence, by (1.3.6) there are $\binom{52}{5}$ poker hands. If the deck is well shuffled, each hand should be equilike; i.e., each hand has probability $1/\binom{52}{5}$. We can now compute the probabilities of some interesting poker hands. Let E_1 be the event of a flush, all five cards of the same suit. There are $\binom{4}{1} = 4$ suits to choose for the flush and in each suit there are $\binom{13}{5}$ possible hands; hence, using the multiplication rule, the probability of getting a flush is

$$P(E_1) = \frac{\binom{4}{1} \binom{13}{5}}{\binom{52}{5}} = \frac{4 \cdot 1287}{2598960} = 0.00198.$$

Real poker players note that this includes the probability of obtaining a straight flush.

Next, consider the probability of the event E_2 of getting exactly three of a kind, (the other two cards are distinct and are of different kinds). Choose the kind for the three, in $\binom{13}{1}$ ways; choose the three, in $\binom{4}{3}$ ways; choose the other two kinds, in $\binom{12}{2}$ ways; and choose one card from each of these last two kinds, in $\binom{4}{1} \binom{4}{1}$ ways. Hence the probability of exactly three of a kind is

$$P(E_2) = \frac{\binom{13}{1} \binom{4}{3} \binom{12}{2} \binom{4}{1}^2}{\binom{52}{5}} = 0.0211.$$

Now suppose that E_3 is the set of outcomes in which exactly three cards are kings and exactly two cards are queens. Select the kings, in $\binom{4}{3}$ ways, and select the queens, in $\binom{4}{2}$ ways. Hence, the probability of E_3 is

$$P(E_3) = \binom{4}{3} \binom{4}{2} / \binom{52}{5} = 0.0000093.$$

The event E_3 is an example of a full house: three of one kind and two of another kind. Exercise 1.3.19 asks for the determination of the probability of a full house.

■

1.3.2 Additional Properties of Probability

We end this section with several additional properties of probability which prove useful in the sequel. Recall in Exercise 1.2.6 we said that a sequence of events $\{C_n\}$ is a nondecreasing sequence if $C_n \subset C_{n+1}$, for all n , in which case we wrote $\lim_{n \rightarrow \infty} C_n = \cup_{n=1}^{\infty} C_n$. Consider $\lim_{n \rightarrow \infty} P(C_n)$. The question is: can we legitimately interchange the limit and P ? As the following theorem shows, the answer is yes. The result also holds for a decreasing sequence of events. Because of this interchange, this theorem is sometimes referred to as the continuity theorem of probability.

Theorem 1.3.6. Let $\{C_n\}$ be a nondecreasing sequence of events. Then

$$\lim_{n \rightarrow \infty} P(C_n) = P\left(\lim_{n \rightarrow \infty} C_n\right) = P\left(\bigcup_{n=1}^{\infty} C_n\right). \quad (1.3.8)$$

Let $\{C_n\}$ be a decreasing sequence of events. Then

$$\lim_{n \rightarrow \infty} P(C_n) = P\left(\lim_{n \rightarrow \infty} C_n\right) = P\left(\bigcap_{n=1}^{\infty} C_n\right). \quad (1.3.9)$$

Proof. We prove the result (1.3.8) and leave the second result as Exercise 1.3.20. Define the sets, called rings, as $R_1 = C_1$ and, for $n > 1$, $R_n = C_n \cap C_{n-1}^c$. It follows that $\bigcup_{n=1}^{\infty} C_n = \bigcup_{n=1}^{\infty} R_n$ and that $R_m \cap R_n = \emptyset$, for $m \neq n$. Also, $P(R_n) = P(C_n) - P(C_{n-1})$. Applying the third axiom of probability yields the following string of equalities:

$$\begin{aligned} P\left[\lim_{n \rightarrow \infty} C_n\right] &= P\left(\bigcup_{n=1}^{\infty} C_n\right) = P\left(\bigcup_{n=1}^{\infty} R_n\right) = \sum_{n=1}^{\infty} P(R_n) = \lim_{n \rightarrow \infty} \sum_{j=1}^n P(R_j) \\ &= \lim_{n \rightarrow \infty} \left\{ P(C_1) + \sum_{j=2}^n [P(C_j) - P(C_{j-1})] \right\} = \lim_{n \rightarrow \infty} P(C_n). \end{aligned} \quad (1.3.10)$$

This is the desired result. ■

Another useful result for arbitrary unions is given by

Theorem 1.3.7 (Boole's Inequality). Let $\{C_n\}$ be an arbitrary sequence of events. Then

$$P\left(\bigcup_{n=1}^{\infty} C_n\right) \leq \sum_{n=1}^{\infty} P(C_n). \quad (1.3.11)$$

Proof: Let $D_n = \bigcup_{i=1}^n C_i$. Then $\{D_n\}$ is an increasing sequence of events that go up to $\bigcup_{n=1}^{\infty} C_n$. Also, for all j , $D_j = D_{j-1} \cup C_j$. Hence, by Theorem 1.3.5,

$$P(D_j) \leq P(D_{j-1}) + P(C_j),$$

that is,

$$P(D_j) - P(D_{j-1}) \leq P(C_j).$$

In this case, the C_i s are replaced by the D_i s in expression (1.3.10). Hence, using the above inequality in this expression and the fact that $P(C_1) = P(D_1)$, we have

$$\begin{aligned} P\left(\bigcup_{n=1}^{\infty} C_n\right) &= P\left(\bigcup_{n=1}^{\infty} D_n\right) = \lim_{n \rightarrow \infty} \left\{ P(D_1) + \sum_{j=2}^n [P(D_j) - P(D_{j-1})] \right\} \\ &\leq \lim_{n \rightarrow \infty} \sum_{j=1}^n P(C_j) = \sum_{n=1}^{\infty} P(C_n). \quad \blacksquare \end{aligned}$$

Theorem 1.3.5 gave a general additive law of probability for the union of two events. As the next remark shows, this can be extended to an additive law for an arbitrary union.

Remark 1.3.2 (Inclusion Exclusion Formula). It is easy to show (Exercise 1.3.9) that

$$P(C_1 \cup C_2 \cup C_3) = p_1 - p_2 + p_3,$$

where

$$\begin{aligned} p_1 &= P(C_1) + P(C_2) + P(C_3) \\ p_2 &= P(C_1 \cap C_2) + P(C_1 \cap C_3) + P(C_2 \cap C_3) \\ p_3 &= P(C_1 \cap C_2 \cap C_3). \end{aligned} \quad (1.3.12)$$

This can be generalized to the **inclusion exclusion formula**:

$$P(C_1 \cup C_2 \cup \dots \cup C_k) = p_1 - p_2 + p_3 - \dots + (-1)^{k+1} p_k, \quad (1.3.13)$$

where p_i equals the sum of the probabilities of all possible intersections involving i sets.

When $k = 3$, it follows that $p_1 \geq p_2 \geq p_3$, but more generally $p_1 \geq p_2 \geq \dots \geq p_k$. As shown in Theorem 1.3.7,

$$p_1 = P(C_1) + P(C_2) + \dots + P(C_k) \geq P(C_1 \cup C_2 \cup \dots \cup C_k).$$

For $k = 2$, we have

$$1 \geq P(C_1 \cup C_2) = P(C_1) + P(C_2) - P(C_1 \cap C_2),$$

which gives **Bonferroni's inequality**,

$$P(C_1 \cap C_2) \geq P(C_1) + P(C_2) - 1, \quad (1.3.14)$$

that is only useful when $P(C_1)$ and $P(C_2)$ are large. The inclusion exclusion formula provides other inequalities that are useful, such as

$$p_1 \geq P(C_1 \cup C_2 \cup \dots \cup C_k) \geq p_1 - p_2$$

and

$$p_1 - p_2 + p_3 \geq P(C_1 \cup C_2 \cup \dots \cup C_k) \geq p_1 - p_2 + p_3 - p_4. \blacksquare$$

EXERCISES

1.3.1. A positive integer from one to six is to be chosen by casting a die. Thus the elements c of the sample space \mathcal{C} are $1, 2, 3, 4, 5, 6$. Suppose $C_1 = \{1, 2, 3, 4\}$ and $C_2 = \{3, 4, 5, 6\}$. If the probability set function P assigns a probability of $\frac{1}{6}$ to each of the elements of \mathcal{C} , compute $P(C_1)$, $P(C_2)$, $P(C_1 \cap C_2)$, and $P(C_1 \cup C_2)$.

1.3.2. A random experiment consists of drawing a card from an ordinary deck of 52 playing cards. Let the probability set function P assign a probability of $\frac{1}{52}$ to each of the 52 possible outcomes. Let C_1 denote the collection of the 13 hearts and let C_2 denote the collection of the 4 kings. Compute $P(C_1)$, $P(C_2)$, $P(C_1 \cap C_2)$, and $P(C_1 \cup C_2)$.

1.3.3. A coin is to be tossed as many times as necessary to turn up one head. Thus the elements c of the sample space \mathcal{C} are H , TH , TTH , TTT , and so forth. Let the probability set function P assign to these elements the respective probabilities $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}$, and so forth. Show that $P(\mathcal{C}) = 1$. Let $C_1 = \{c : c \text{ is } H, TH, TTH, \text{ or } TTT\}$. Compute $P(C_1)$. Next, suppose that $C_2 = \{c : c \text{ is } TTT \text{ or } TTTT\}$. Compute $P(C_2)$, $P(C_1 \cap C_2)$, and $P(C_1 \cup C_2)$.

1.3.4. If the sample space is $\mathcal{C} = C_1 \cup C_2$ and if $P(C_1) = 0.8$ and $P(C_2) = 0.5$, find $P(C_1 \cap C_2)$.

1.3.5. Let the sample space be $\mathcal{C} = \{c : 0 < c < \infty\}$. Let $C \subset \mathcal{C}$ be defined by $C = \{c : 4 < c < \infty\}$ and take $P(C) = \int_C e^{-x} dx$. Show that $P(\mathcal{C}) = 1$. Evaluate $P(C)$, $P(C^c)$, and $P(C \cup C^c)$.

1.3.6. If the sample space is $\mathcal{C} = \{c : -\infty < c < \infty\}$ and if $C \subset \mathcal{C}$ is a set for which the integral $\int_C e^{-|x|} dx$ exists, show that this set function is not a probability set function. What constant do we multiply the integrand by to make it a probability set function?

1.3.7. If C_1 and C_2 are subsets of the sample space \mathcal{C} , show that

$$P(C_1 \cap C_2) \leq P(C_1) \leq P(C_1 \cup C_2) \leq P(C_1) + P(C_2).$$

1.3.8. Let C_1 , C_2 , and C_3 be three mutually disjoint subsets of the sample space \mathcal{C} . Find $P[(C_1 \cup C_2) \cap C_3]$ and $P(C_1^c \cup C_2^c)$.

1.3.9. Consider Remark 1.3.2.

(a) If C_1 , C_2 , and C_3 are subsets of \mathcal{C} , show that

$$\begin{aligned} P(C_1 \cup C_2 \cup C_3) &= P(C_1) + P(C_2) + P(C_3) - P(C_1 \cap C_2) \\ &\quad - P(C_1 \cap C_3) - P(C_2 \cap C_3) + P(C_1 \cap C_2 \cap C_3). \end{aligned}$$

(b) Now prove the general inclusion exclusion formula given by the expression (1.3.13).

Remark 1.3.3. In order to solve Exercises (1.3.10)–(1.3.19), certain reasonable assumptions must be made. ■

1.3.10. A bowl contains 16 chips, of which 6 are red, 7 are white, and 3 are blue. If four chips are taken at random and without replacement, find the probability that: (a) each of the four chips is red; (b) none of the four chips is red; (c) there is at least one chip of each color.

1.3.11. A person has purchased 10 of 1000 tickets sold in a certain raffle. To determine the five prize winners, five tickets are to be drawn at random and without replacement. Compute the probability that this person wins at least one prize.

Hint: First compute the probability that the person does not win a prize.

1.3.12. Compute the probability of being dealt at random and without replacement a 13-card bridge hand consisting of: (a) 6 spades, 4 hearts, 2 diamonds, and 1 club; (b) 13 cards of the same suit.

1.3.13. Three distinct integers are chosen at random from the first 20 positive integers. Compute the probability that: (a) their sum is even; (b) their product is even.

1.3.14. There are five red chips and three blue chips in a bowl. The red chips are numbered 1, 2, 3, 4, 5, respectively, and the blue chips are numbered 1, 2, 3, respectively. If two chips are to be drawn at random and without replacement, find the probability that these chips have either the same number or the same color.

1.3.15. In a lot of 50 light bulbs, there are 2 bad bulbs. An inspector examines five bulbs, which are selected at random and without replacement.

(a) Find the probability of at least one defective bulb among the five.

(b) How many bulbs should be examined so that the probability of finding at least one bad bulb exceeds $\frac{1}{2}$?

1.3.16. For the birthday problem, Example 1.3.3, use the given R function `bday` to determine the value of n so that $p(n) \geq 0.5$ and $p(n-1) < 0.5$, where $p(n)$ is the probability that at least two people in the room of n people have the same birthday.

1.3.17. If C_1, \dots, C_k are k events in the sample space \mathcal{C} , show that the probability that at least one of the events occurs is one minus the probability that none of them occur; i.e.,

$$P(C_1 \cup \dots \cup C_k) = 1 - P(C_1^c \cap \dots \cap C_k^c). \quad (1.3.15)$$

1.3.18. A secretary types three letters and the three corresponding envelopes. In a hurry, he places at random one letter in each envelope. What is the probability that at least one letter is in the correct envelope? *Hint:* Let C_i be the event that the i th letter is in the correct envelope. Expand $P(C_1 \cup C_2 \cup C_3)$ to determine the probability.

1.3.19. Consider poker hands drawn from a well-shuffled deck as described in Example 1.3.4. Determine the probability of a full house, i.e, three of one kind and two of another.

1.3.20. Prove expression (1.3.9).

1.3.21. Suppose the experiment is to choose a real number at random in the interval $(0, 1)$. For any subinterval $(a, b) \subset (0, 1)$, it seems reasonable to assign the probability $P[(a, b)] = b - a$; i.e., the probability of selecting the point from a subinterval is directly proportional to the length of the subinterval. If this is the case, choose an appropriate sequence of subintervals and use expression (1.3.9) to show that $P[\{a\}] = 0$, for all $a \in (0, 1)$.

1.3.22. Consider the events C_1, C_2, C_3 .

- (a) Suppose C_1, C_2, C_3 are mutually exclusive events. If $P(C_i) = p_i$, $i = 1, 2, 3$, what is the restriction on the sum $p_1 + p_2 + p_3$?
- (b) In the notation of part (a), if $p_1 = 4/10$, $p_2 = 3/10$, and $p_3 = 5/10$, are C_1, C_2, C_3 mutually exclusive?

For the last two exercises it is assumed that the reader is familiar with σ -fields.

1.3.23. Suppose \mathcal{D} is a nonempty collection of subsets of \mathcal{C} . Consider the collection of events

$$\mathcal{B} = \cap\{\mathcal{E} : \mathcal{D} \subset \mathcal{E} \text{ and } \mathcal{E} \text{ is a } \sigma\text{-field}\}.$$

Note that $\phi \in \mathcal{B}$ because it is in each σ -field, and, hence, in particular, it is in each σ -field $\mathcal{E} \supset \mathcal{D}$. Continue in this way to show that \mathcal{B} is a σ -field.

1.3.24. Let $\mathcal{C} = R$, where R is the set of all real numbers. Let \mathcal{I} be the set of all open intervals in R . The Borel σ -field on the real line is given by

$$\mathcal{B}_0 = \cap\{\mathcal{E} : \mathcal{I} \subset \mathcal{E} \text{ and } \mathcal{E} \text{ is a } \sigma\text{-field}\}.$$

By definition, \mathcal{B}_0 contains the open intervals. Because $[a, \infty) = (-\infty, a)^c$ and \mathcal{B}_0 is closed under complements, it contains all intervals of the form $[a, \infty)$, for $a \in R$. Continue in this way and show that \mathcal{B}_0 contains all the closed and half-open intervals of real numbers.

1.4 Conditional Probability and Independence

In some random experiments, we are interested only in those outcomes that are elements of a subset A of the sample space \mathcal{C} . This means, for our purposes, that the sample space is effectively the subset A . We are now confronted with the problem of defining a probability set function with A as the “new” sample space.

Let the probability set function $P(A)$ be defined on the sample space \mathcal{C} and let A be a subset of \mathcal{C} such that $P(A) > 0$. We agree to consider only those outcomes of the random experiment that are elements of A ; in essence, then, we take A to be a sample space. Let B be another subset of \mathcal{C} . How, relative to the new sample space A , do we want to define the probability of the event B ? Once defined, this probability is called the *conditional probability* of the event B , relative to the hypothesis of the event A , or, more briefly, the conditional probability of B , given A . Such a conditional probability is denoted by the symbol $P(B|A)$. The “|” in this symbol is usually read as “given.” We now return to the question that was raised about the definition of this symbol. Since A is now the sample space, the only elements of B that concern us are those, if any, that are also elements of A , that is, the elements of $A \cap B$. It seems desirable, then, to define the symbol $P(B|A)$ in such a way that

$$P(A|A) = 1 \quad \text{and} \quad P(B|A) = P(A \cap B|A).$$

Moreover, from a relative frequency point of view, it would seem logically inconsistent if we did not require that the ratio of the probabilities of the events $A \cap B$ and A , relative to the space A , be the same as the ratio of the probabilities of these events relative to the space \mathcal{C} ; that is, we should have

$$\frac{P(A \cap B|A)}{P(A|A)} = \frac{P(A \cap B)}{P(A)}.$$

These three desirable conditions imply that the relation conditional probability is reasonably defined as

Definition 1.4.1 (Conditional Probability). *Let B and A be events with $P(A) > 0$. Then we defined the **conditional probability** of B given A as*

$$P(B|A) = \frac{P(A \cap B)}{P(A)}. \blacksquare \quad (1.4.1)$$

Moreover, we have

1. $P(B|A) \geq 0$.
2. $P(A|A) = 1$.
3. $P(\cup_{n=1}^{\infty} B_n|A) = \sum_{n=1}^{\infty} P(B_n|A)$, provided that B_1, B_2, \dots are mutually exclusive events.

Properties (1) and (2) are evident. For Property (3), suppose the sequence of events B_1, B_2, \dots is mutually exclusive. It follows that also $(B_n \cap A) \cap (B_m \cap A) = \emptyset$, $n \neq m$. Using this and the first of the distributive laws (1.2.5) for countable unions, we have

$$\begin{aligned} P(\cup_{n=1}^{\infty} B_n|A) &= \frac{P[\cup_{n=1}^{\infty} (B_n \cap A)]}{P(A)} \\ &= \sum_{n=1}^{\infty} \frac{P[B_n \cap A]}{P(A)} \\ &= \sum_{n=1}^{\infty} P[B_n|A]. \end{aligned}$$

Properties (1)–(3) are precisely the conditions that a probability set function must satisfy. Accordingly, $P(B|A)$ is a probability set function, defined for subsets of A . It may be called the conditional probability set function, relative to the hypothesis A , or the conditional probability set function, given A . It should be noted that this conditional probability set function, given A , is defined at this time only when $P(A) > 0$.

Example 1.4.1. A hand of five cards is to be dealt at random without replacement from an ordinary deck of 52 playing cards. The conditional probability of an all-spade hand (B), relative to the hypothesis that there are at least four spades in the

hand (A), is, since $A \cap B = B$,

$$\begin{aligned} P(B|A) &= \frac{P(B)}{P(A)} = \frac{\binom{13}{5}/\binom{52}{5}}{\left[\binom{13}{4}\binom{39}{1} + \binom{13}{5}\right]/\binom{52}{5}} \\ &= \frac{\binom{13}{5}}{\binom{13}{4}\binom{39}{1} + \binom{13}{5}} = 0.0441. \end{aligned}$$

Note that this is not the same as drawing for a spade to complete a flush in draw poker; see Exercise 1.4.3. ■

From the definition of the conditional probability set function, we observe that

$$P(A \cap B) = P(A)P(B|A).$$

This relation is frequently called the **multiplication rule** for probabilities. Sometimes, after considering the nature of the random experiment, it is possible to make reasonable assumptions so that both $P(A)$ and $P(B|A)$ can be assigned. Then $P(A \cap B)$ can be computed under these assumptions. This is illustrated in Examples 1.4.2 and 1.4.3.

Example 1.4.2. A bowl contains eight chips. Three of the chips are red and the remaining five are blue. Two chips are to be drawn successively, at random and without replacement. We want to compute the probability that the first draw results in a red chip (A) and that the second draw results in a blue chip (B). It is reasonable to assign the following probabilities:

$$P(A) = \frac{3}{8} \quad \text{and} \quad P(B|A) = \frac{5}{7}.$$

Thus, under these assignments, we have $P(A \cap B) = \left(\frac{3}{8}\right)\left(\frac{5}{7}\right) = \frac{15}{56} = 0.2679$. ■

Example 1.4.3. From an ordinary deck of playing cards, cards are to be drawn successively, at random and without replacement. The probability that the third spade appears on the sixth draw is computed as follows. Let A be the event of two spades in the first five draws and let B be the event of a spade on the sixth draw. Thus the probability that we wish to compute is $P(A \cap B)$. It is reasonable to take

$$P(A) = \frac{\binom{13}{2}\binom{39}{3}}{\binom{52}{5}} = 0.2743 \quad \text{and} \quad P(B|A) = \frac{11}{47} = 0.2340.$$

The desired probability $P(A \cap B)$ is then the product of these two numbers, which to four places is 0.0642. ■

The multiplication rule can be extended to three or more events. In the case of three events, we have, by using the multiplication rule for two events,

$$\begin{aligned} P(A \cap B \cap C) &= P[(A \cap B) \cap C] \\ &= P(A \cap B)P(C|A \cap B). \end{aligned}$$

But $P(A \cap B) = P(A)P(B|A)$. Hence, provided $P(A \cap B) > 0$,

$$P(A \cap B \cap C) = P(A)P(B|A)P(C|A \cap B).$$

This procedure can be used to extend the multiplication rule to four or more events. The general formula for k events can be proved by mathematical induction.

Example 1.4.4. Four cards are to be dealt successively, at random and without replacement, from an ordinary deck of playing cards. The probability of receiving a spade, a heart, a diamond, and a club, in that order, is $(\frac{13}{52})(\frac{13}{51})(\frac{13}{50})(\frac{13}{49}) = 0.0044$. This follows from the extension of the multiplication rule. ■

Consider k mutually exclusive and exhaustive events A_1, A_2, \dots, A_k such that $P(A_i) > 0$, $i = 1, 2, \dots, k$; i.e., A_1, A_2, \dots, A_k form a partition of \mathcal{C} . Here the events A_1, A_2, \dots, A_k do *not* need to be equally likely. Let B be another event such that $P(B) > 0$. Thus B occurs with one and only one of the events A_1, A_2, \dots, A_k ; that is,

$$\begin{aligned} B &= B \cap (A_1 \cup A_2 \cup \dots \cup A_k) \\ &= (B \cap A_1) \cup (B \cap A_2) \cup \dots \cup (B \cap A_k). \end{aligned}$$

Since $B \cap A_i$, $i = 1, 2, \dots, k$, are mutually exclusive, we have

$$P(B) = P(B \cap A_1) + P(B \cap A_2) + \dots + P(B \cap A_k).$$

However, $P(B \cap A_i) = P(A_i)P(B|A_i)$, $i = 1, 2, \dots, k$; so

$$\begin{aligned} P(B) &= P(A_1)P(B|A_1) + P(A_2)P(B|A_2) + \dots + P(A_k)P(B|A_k) \\ &= \sum_{i=1}^k P(A_i)P(B|A_i). \end{aligned} \tag{1.4.2}$$

This result is sometimes called the **law of total probability** and it leads to the following important theorem.

Theorem 1.4.1 (Bayes). *Let A_1, A_2, \dots, A_k be events such that $P(A_i) > 0$, $i = 1, 2, \dots, k$. Assume further that A_1, A_2, \dots, A_k form a partition of the sample space \mathcal{C} . Let B be any event. Then*

$$P(A_j|B) = \frac{P(A_j)P(B|A_j)}{\sum_{i=1}^k P(A_i)P(B|A_i)}, \tag{1.4.3}$$

Proof: Based on the definition of conditional probability, we have

$$P(A_j|B) = \frac{P(B \cap A_j)}{P(B)} = \frac{P(A_j)P(B|A_j)}{P(B)}.$$

The result then follows by the law of total probability, (1.4.2). ■

This theorem is the well-known **Bayes' Theorem**. This permits us to calculate the conditional probability of A_j , given B , from the probabilities of A_1, A_2, \dots, A_k and the conditional probabilities of B , given A_i , $i = 1, 2, \dots, k$. The next three examples illustrate the usefulness of Bayes Theorem to determine probabilities.

Example 1.4.5. Say it is known that bowl A_1 contains three red and seven blue chips and bowl A_2 contains eight red and two blue chips. All chips are identical in size and shape. A die is cast and bowl A_1 is selected if five or six spots show on the side that is up; otherwise, bowl A_2 is selected. For this situation, it seems reasonable to assign $P(A_1) = \frac{2}{6}$ and $P(A_2) = \frac{4}{6}$. The selected bowl is handed to another person and one chip is taken at random. Say that this chip is red, an event which we denote by B . By considering the contents of the bowls, it is reasonable to assign the conditional probabilities $P(B|A_1) = \frac{3}{10}$ and $P(B|A_2) = \frac{8}{10}$. Thus the conditional probability of bowl A_1 , given that a red chip is drawn, is

$$\begin{aligned} P(A_1|B) &= \frac{P(A_1)P(B|A_1)}{P(A_1)P(B|A_1) + P(A_2)P(B|A_2)} \\ &= \frac{\left(\frac{2}{6}\right)\left(\frac{3}{10}\right)}{\left(\frac{2}{6}\right)\left(\frac{3}{10}\right) + \left(\frac{4}{6}\right)\left(\frac{8}{10}\right)} = \frac{3}{19}. \end{aligned}$$

In a similar manner, we have $P(A_2|B) = \frac{16}{19}$. ■

In Example 1.4.5, the probabilities $P(A_1) = \frac{2}{6}$ and $P(A_2) = \frac{4}{6}$ are called **prior probabilities** of A_1 and A_2 , respectively, because they are known to be due to the random mechanism used to select the bowls. After the chip is taken and is observed to be red, the conditional probabilities $P(A_1|B) = \frac{3}{19}$ and $P(A_2|B) = \frac{16}{19}$ are called **posterior probabilities**. Since A_2 has a larger proportion of red chips than does A_1 , it appeals to one's intuition that $P(A_2|B)$ should be larger than $P(A_2)$ and, of course, $P(A_1|B)$ should be smaller than $P(A_1)$. That is, intuitively the chances of having bowl A_2 are better once that a red chip is observed than before a chip is taken. Bayes' theorem provides a method of determining exactly what those probabilities are.

Example 1.4.6. Three plants, A_1 , A_2 , and A_3 , produce respectively, 10%, 50%, and 40% of a company's output. Although plant A_1 is a small plant, its manager believes in high quality and only 1% of its products are defective. The other two, A_2 and A_3 , are worse and produce items that are 3% and 4% defective, respectively. All products are sent to a central warehouse. One item is selected at random and observed to be defective, say event B . The conditional probability that it comes from plant A_1 is found as follows. It is natural to assign the respective prior probabilities of getting an item from the plants as $P(A_1) = 0.1$, $P(A_2) = 0.5$, and $P(A_3) = 0.4$, while the conditional probabilities of defective items are $P(B|A_1) = 0.01$, $P(B|A_2) = 0.03$, and $P(B|A_3) = 0.04$. Thus the posterior probability of A_1 , given a defective, is

$$P(A_1|B) = \frac{P(A_1 \cap B)}{P(B)} = \frac{(0.1)(0.01)}{(0.1)(0.01) + (0.5)(0.03) + (0.4)(0.04)} = \frac{1}{32}.$$

This is much smaller than the prior probability $P(A_1) = \frac{1}{10}$. This is as it should be because the fact that the item is defective decreases the chances that it comes from the high-quality plant A_1 . ■

Example 1.4.7. Suppose we want to investigate the percentage of abused children in a certain population. The events of interest are: a child is abused (A) and its complement a child is not abused ($N = A^c$). For the purposes of this example, we assume that $P(A) = 0.01$ and, hence, $P(N) = 0.99$. The classification as to whether a child is abused or not is based upon a doctor's examination. Because doctors are not perfect, they sometimes classify an abused child (A) as one that is not abused (N_D , where N_D means classified as not abused by a doctor). On the other hand, doctors sometimes classify a nonabused child (N) as abused (A_D). Suppose these error rates of misclassification are $P(N_D | A) = 0.04$ and $P(A_D | N) = 0.05$; thus the probabilities of correct decisions are $P(A_D | A) = 0.96$ and $P(N_D | N) = 0.95$. Let us compute the probability that a child taken at random is classified as abused by a doctor. Because this can happen in two ways, $A \cap A_D$ or $N \cap A_D$, we have

$$P(A_D) = P(A_D | A)P(A) + P(A_D | N)P(N) = (0.96)(0.01) + (0.05)(0.99) = 0.0591,$$

which is quite high relative to the probability of an abused child, 0.01. Further, the probability that a child is abused when the doctor classified the child as abused is

$$P(A | A_D) = \frac{P(A \cap A_D)}{P(A_D)} = \frac{(0.96)(0.01)}{0.0591} = 0.1624,$$

which is quite low. In the same way, the probability that a child is not abused when the doctor classified the child as abused is 0.8376, which is quite high. The reason that these probabilities are so poor at recording the true situation is that the doctors' error rates are so high relative to the fraction 0.01 of the population that is abused. An investigation such as this would, hopefully, lead to better training of doctors for classifying abused children. See also Exercise 1.4.17. ■

1.4.1 Independence

Sometimes it happens that the occurrence of event A does not change the probability of event B ; that is, when $P(A) > 0$,

$$P(B|A) = P(B).$$

In this case, we say that the events A and B are *independent*. Moreover, the multiplication rule becomes

$$P(A \cap B) = P(A)P(B|A) = P(A)P(B). \quad (1.4.4)$$

This, in turn, implies, when $P(B) > 0$, that

$$P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(A)P(B)}{P(B)} = P(A).$$

Note that if $P(A) > 0$ and $P(B) > 0$, then by the above discussion, independence is equivalent to

$$P(A \cap B) = P(A)P(B). \quad (1.4.5)$$

What if either $P(A) = 0$ or $P(B) = 0$? In either case, the right side of (1.4.5) is 0. However, the left side is 0 also because $A \cap B \subset A$ and $A \cap B \subset B$. Hence, we take Equation (1.4.5) as our formal definition of independence; that is,

Definition 1.4.2. Let A and B be two events. We say that A and B are **independent** if $P(A \cap B) = P(A)P(B)$. ■

Suppose A and B are independent events. Then the following three pairs of events are independent: A^c and B , A and B^c , and A^c and B^c . We show the first and leave the other two to the exercises; see Exercise 1.4.11. Using the disjoint union, $B = (A^c \cap B) \cup (A \cap B)$, we have

$$P(A^c \cap B) = P(B) - P(A \cap B) = P(B) - P(A)P(B) = [1 - P(A)]P(B) = P(A^c)P(B). \quad (1.4.6)$$

Hence, A^c and B are also independent.

Remark 1.4.1. Events that are *independent* are sometimes called *statistically independent*, *stochastically independent*, or *independent in a probability sense*. In most instances, we use *independent* without a modifier if there is no possibility of misunderstanding. ■

Example 1.4.8. A red die and a white die are cast in such a way that the numbers of spots on the two sides that are up are independent events. If A represents a four on the red die and B represents a three on the white die, with an equally likely assumption for each side, we assign $P(A) = \frac{1}{6}$ and $P(B) = \frac{1}{6}$. Thus, from independence, the probability of the ordered pair (red = 4, white = 3) is

$$P[(4, 3)] = \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) = \frac{1}{36}.$$

The probability that the sum of the up spots of the two dice equals seven is

$$\begin{aligned} &P[(1, 6), (2, 5), (3, 4), (4, 3), (5, 2), (6, 1)] \\ &= \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) + \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) + \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) + \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) + \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) + \left(\frac{1}{6}\right)\left(\frac{1}{6}\right) = \frac{6}{36}. \end{aligned}$$

In a similar manner, it is easy to show that the probabilities of the sums of the upfaces 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12 are, respectively,

$$\frac{1}{36}, \frac{2}{36}, \frac{3}{36}, \frac{4}{36}, \frac{5}{36}, \frac{6}{36}, \frac{5}{36}, \frac{4}{36}, \frac{3}{36}, \frac{2}{36}, \frac{1}{36}. \quad \blacksquare$$

Suppose now that we have three events, A_1 , A_2 , and A_3 . We say that they are **mutually independent** if and only if they are *pairwise independent*:

$$\begin{aligned} P(A_1 \cap A_3) &= P(A_1)P(A_3), & P(A_1 \cap A_2) &= P(A_1)P(A_2), \\ P(A_2 \cap A_3) &= P(A_2)P(A_3), \end{aligned}$$

and

$$P(A_1 \cap A_2 \cap A_3) = P(A_1)P(A_2)P(A_3).$$

More generally, the n events A_1, A_2, \dots, A_n are **mutually independent** if and only if for every collection of k of these events, $2 \leq k \leq n$, and for every permutation d_1, d_2, \dots, d_k of $1, 2, \dots, k$,

$$P(A_{d_1} \cap A_{d_2} \cap \cdots \cap A_{d_k}) = P(A_{d_1})P(A_{d_2}) \cdots P(A_{d_k}).$$

In particular, if A_1, A_2, \dots, A_n are mutually independent, then

$$P(A_1 \cap A_2 \cap \cdots \cap A_n) = P(A_1)P(A_2) \cdots P(A_n).$$

Also, as with two sets, many combinations of these events and their complements are independent, such as

1. The events A_1^c and $A_2 \cup A_3^c \cup A_4$ are independent,
2. The events $A_1 \cup A_2^c$, A_3^c and $A_4 \cap A_5^c$ are mutually independent.

If there is no possibility of misunderstanding, *independent* is often used without the modifier *mutually* when considering more than two events.

Example 1.4.9. Pairwise independence does not imply mutual independence. As an example, suppose we twice spin a fair spinner with the numbers 1, 2, 3, and 4. Let A_1 be the event that the sum of the numbers spun is 5, let A_2 be the event that the first number spun is a 1, and let A_3 be the event that the second number spun is a 4. Then $P(A_i) = 1/4$, $i = 1, 2, 3$, and for $i \neq j$, $P(A_i \cap A_j) = 1/16$. So the three events are pairwise independent. But $A_1 \cap A_2 \cap A_3$ is the event that (1, 4) is spun, which has probability $1/16 \neq 1/64 = P(A_1)P(A_2)P(A_3)$. Hence the events A_1 , A_2 , and A_3 are not mutually independent. ■

We often perform a sequence of random experiments in such a way that the events associated with one of them are independent of the events associated with the others. For convenience, we refer to these events as outcomes of *independent experiments*, meaning that the respective events are independent. Thus we often refer to independent flips of a coin or independent casts of a die or, more generally, independent trials of some given random experiment.

Example 1.4.10. A coin is flipped independently several times. Let the event A_i represent a head (H) on the i th toss; thus A_i^c represents a tail (T). Assume that A_i and A_i^c are equally likely; that is, $P(A_i) = P(A_i^c) = \frac{1}{2}$. Thus the probability of an ordered sequence like HHTH is, from independence,

$$P(A_1 \cap A_2 \cap A_3^c \cap A_4) = P(A_1)P(A_2)P(A_3^c)P(A_4) = \left(\frac{1}{2}\right)^4 = \frac{1}{16}.$$

Similarly, the probability of observing the first head on the third flip is

$$P(A_1^c \cap A_2^c \cap A_3) = P(A_1^c)P(A_2^c)P(A_3) = \left(\frac{1}{2}\right)^3 = \frac{1}{8}.$$

Also, the probability of getting at least one head on four flips is

$$\begin{aligned} P(A_1 \cup A_2 \cup A_3 \cup A_4) &= 1 - P[(A_1 \cup A_2 \cup A_3 \cup A_4)^c] \\ &= 1 - P(A_1^c \cap A_2^c \cap A_3^c \cap A_4^c) \\ &= 1 - \left(\frac{1}{2}\right)^4 = \frac{15}{16}. \end{aligned}$$

See Exercise 1.4.13 to justify this last probability. ■

Example 1.4.11. A computer system is built so that if component K_1 fails, it is bypassed and K_2 is used. If K_2 fails, then K_3 is used. Suppose that the probability that K_1 fails is 0.01, that K_2 fails is 0.03, and that K_3 fails is 0.08. Moreover, we can assume that the failures are mutually independent events. Then the probability of failure of the system is

$$(0.01)(0.03)(0.08) = 0.000024,$$

as all three components would have to fail. Hence, the probability that the system does not fail is $1 - 0.000024 = 0.999976$. ■

1.4.2 Simulations

Many of the exercises at the end of this section are designed to aid the reader in his/her understanding of the concepts of conditional probability and independence. With diligence and patience, the reader will derive the exact answer. Many real life problems, though, are too complicated to allow for exact derivation. In such cases, scientists often turn to computer simulations to estimate the answer. As an example, suppose for an experiment, we want to obtain $P(A)$ for some event A . A program is written that performs one trial (one simulation) of the experiment and it records whether or not A occurs. We then obtain n independent simulations (runs) of the program. Denote by \hat{p}_n the proportion of these n simulations in which A occurred. Then \hat{p}_n is our estimate of the $P(A)$. Besides the estimation of $P(A)$, we also obtain an error of estimation given by $1.96 * \sqrt{\hat{p}_n(1 - \hat{p}_n)/n}$. As we discuss theoretically in Chapter 4, we are 95% confident that $P(A)$ lies in the interval

$$\hat{p}_n \pm 1.96 \sqrt{\frac{\hat{p}_n(1 - \hat{p}_n)}{n}}. \quad (1.4.7)$$

In Chapter 4, we call this interval a **95% confidence interval** for $P(A)$. For now, we make use of this confidence interval for our simulations.

Example 1.4.12. As an example, consider the game:

Person A tosses a coin and then person B rolls a die. This is repeated independently until a head or one of the numbers 1, 2, 3, 4 appears, at which time the game is stopped. Person A wins with the head and B wins with one of the numbers 1, 2, 3, 4. Compute the probability $P(A)$ that person A wins the game.

For an exact derivation, notice that it is implicit in the statement A wins the game that the game is completed. Using abbreviated notation, the game is completed if H or $T\{1, \dots, 4\}$ occurs. Using independence, the probability that A wins is thus the conditional probability $(1/2)/[(1/2) + (1/2)(4/6)] = 3/5$.

The following R function, `abgame`, simulates the problem. This function can be downloaded and sourced at the site discussed in the Preface. The first line of the program sets up the draws for persons A and B , respectively. The second line sets up a flag for the while loop and the returning values, `Awin` and `Bwin` are initialized

at 0. The command `sample(rngA, 1, pr=pA)` draws a sample of size 1 from `rngA` with pmf `pA`. Each execution of the while loop returns one complete game. Further, the executions are independent of one another.

```
abgame <- function(){
  rngA <- c(0,1); pA <- rep(1/2,2); rngB <- 1:6; pB <- rep(1/6,6)
  ic <- 0; Awin <- 0; Bwin <- 0
  while(ic == 0){
    x <- sample(rngA,1,pr=pA)
    if(x==1){
      ic <- 1; Awin <- 1
    } else {
      y <- sample(rngB,1,pr=pB)
      if(y <= 4){ic <- 1; Bwin <- 1}
    }
  }
  return(c(Awin,Bwin))
}
```

Notice that one and only one of `Awin` or `Bwin` receives the value 1 depending on whether or not A or B wins. The next R segment simulates the game 10,000 times and computes the estimate that A wins along with the error of estimation.

```
ind <- 0; nsims <- 10000
for(i in 1:nsims){
  seeA <- abgame()
  if(seeA[1] == 1){ind <- ind + 1}
}
estpA <- ind/nsims
err <- 1.96*sqrt(estpA*(1-estpA)/nsims)
estpA; err
```

An execution of this code resulted in `estpA = 0.6001` and `err = 0.0096`. As noted above the probability that A wins is 0.6 which is in the interval 0.6001 ± 0.0096 . As discussed in Chapter 4, we expect this to occur 95% of the time when using such a confidence interval. ■

EXERCISES

1.4.1. If $P(A_1) > 0$ and if A_2, A_3, A_4, \dots are mutually disjoint sets, show that

$$P(A_2 \cup A_3 \cup \dots | A_1) = P(A_2|A_1) + P(A_3|A_1) + \dots .$$

1.4.2. Assume that $P(A_1 \cap A_2 \cap A_3) > 0$. Prove that

$$P(A_1 \cap A_2 \cap A_3 \cap A_4) = P(A_1)P(A_2|A_1)P(A_3|A_1 \cap A_2)P(A_4|A_1 \cap A_2 \cap A_3).$$

1.4.3. Suppose we are playing draw poker. We are dealt (from a well-shuffled deck) five cards, which contain four spades and another card of a different suit. We decide to discard the card of a different suit and draw one card from the remaining cards to complete a flush in spades (all five cards spades). Determine the probability of completing the flush.

1.4.4. From a well-shuffled deck of ordinary playing cards, four cards are turned over one at a time without replacement. What is the probability that the spades and red cards alternate?

1.4.5. A hand of 13 cards is to be dealt at random and without replacement from an ordinary deck of playing cards. Find the conditional probability that there are at least three kings in the hand given that the hand contains at least two kings.

1.4.6. A drawer contains eight different pairs of socks. If six socks are taken at random and without replacement, compute the probability that there is at least one matching pair among these six socks. *Hint:* Compute the probability that there is not a matching pair.

1.4.7. A pair of dice is cast until either the sum of seven or eight appears.

- (a) Show that the probability of a seven before an eight is $6/11$.
- (b) Next, this pair of dice is cast until a seven appears twice or until each of a six and eight has appeared at least once. Show that the probability of the six and eight occurring before two sevens is 0.546.

1.4.8. In a certain factory, machines I, II, and III are all producing springs of the same length. Machines I, II, and III produce 1%, 4%, and 2% defective springs, respectively. Of the total production of springs in the factory, Machine I produces 30%, Machine II produces 25%, and Machine III produces 45%.

- (a) If one spring is selected at random from the total springs produced in a given day, determine the probability that it is defective.
- (b) Given that the selected spring is defective, find the conditional probability that it was produced by Machine II.

1.4.9. Bowl I contains six red chips and four blue chips. Five of these 10 chips are selected at random and without replacement and put in bowl II, which was originally empty. One chip is then drawn at random from bowl II. Given that this chip is blue, find the conditional probability that two red chips and three blue chips are transferred from bowl I to bowl II.

1.4.10. In an office there are two boxes of thumb drives: Box A_1 contains seven 100 GB drives and three 500 GB drives, and box A_2 contains two 100 GB drives and eight 500 GB drives. A person is handed a box at random with prior probabilities $P(A_1) = \frac{2}{3}$ and $P(A_2) = \frac{1}{3}$, possibly due to the boxes' respective locations. A drive is then selected at random and the event B occurs if it is a 500 GB drive. Using an equally likely assumption for each drive in the selected box, compute $P(A_1|B)$ and $P(A_2|B)$.

1.4.11. Suppose A and B are independent events. In expression (1.4.6) we showed that A^c and B are independent events. Show similarly that the following pairs of events are also independent: (a) A and B^c and (b) A^c and B^c .

1.4.12. Let C_1 and C_2 be independent events with $P(C_1) = 0.6$ and $P(C_2) = 0.3$. Compute (a) $P(C_1 \cap C_2)$, (b) $P(C_1 \cup C_2)$, and (c) $P(C_1 \cup C_2^c)$.

1.4.13. Generalize Exercise 1.2.5 to obtain

$$(C_1 \cup C_2 \cup \dots \cup C_k)^c = C_1^c \cap C_2^c \cap \dots \cap C_k^c.$$

Say that C_1, C_2, \dots, C_k are independent events that have respective probabilities p_1, p_2, \dots, p_k . Argue that the probability of at least one of C_1, C_2, \dots, C_k is equal to

$$1 - (1 - p_1)(1 - p_2) \cdots (1 - p_k).$$

1.4.14. Each of four persons fires one shot at a target. Let C_k denote the event that the target is hit by person k , $k = 1, 2, 3, 4$. If C_1, C_2, C_3, C_4 are independent and if $P(C_1) = P(C_2) = 0.7$, $P(C_3) = 0.9$, and $P(C_4) = 0.4$, compute the probability that (a) all of them hit the target; (b) exactly one hits the target; (c) no one hits the target; (d) at least one hits the target.

1.4.15. A bowl contains three red (R) balls and seven white (W) balls of exactly the same size and shape. Select balls successively at random and with replacement so that the events of white on the first trial, white on the second, and so on, can be assumed to be independent. In four trials, make certain assumptions and compute the probabilities of the following ordered sequences: (a) WWRW; (b) RWWW; (c) WWWR; and (d) WRWW. Compute the probability of exactly one red ball in the four trials.

1.4.16. A coin is tossed two independent times, each resulting in a tail (T) or a head (H). The sample space consists of four ordered pairs: TT, TH, HT, HH. Making certain assumptions, compute the probability of each of these ordered pairs. What is the probability of at least one head?

1.4.17. For Example 1.4.7, obtain the following probabilities. Explain what they mean in terms of the problem.

- (a) $P(N_D)$.
- (b) $P(N | A_D)$.
- (c) $P(A | N_D)$.
- (d) $P(N | N_D)$.

1.4.18. A die is cast independently until the first 6 appears. If the casting stops on an odd number of times, Bob wins; otherwise, Joe wins.

- (a) Assuming the die is fair, what is the probability that Bob wins?

- (b) Let p denote the probability of a 6. Show that the game favors Bob, for all p , $0 < p < 1$.

1.4.19. Cards are drawn at random and with replacement from an ordinary deck of 52 cards until a spade appears.

- (a) What is the probability that at least four draws are necessary?
(b) Same as part (a), except the cards are drawn without replacement.

1.4.20. A person answers each of two multiple choice questions at random. If there are four possible choices on each question, what is the conditional probability that both answers are correct given that at least one is correct?

1.4.21. Suppose a fair 6-sided die is rolled six independent times. A match occurs if side i is observed on the i th trial, $i = 1, \dots, 6$.

- (a) What is the probability of at least one match on the six rolls? *Hint:* Let C_i be the event of a match on the i th trial and use Exercise 1.4.13 to determine the desired probability.
(b) Extend part (a) to a fair n -sided die with n independent rolls. Then determine the limit of the probability as $n \rightarrow \infty$.

1.4.22. Players A and B play a sequence of independent games. Player A throws a die first and wins on a “six.” If he fails, B throws and wins on a “five” or “six.” If he fails, A throws and wins on a “four,” “five,” or “six.” And so on. Find the probability of each player winning the sequence.

1.4.23. Let C_1 , C_2 , C_3 be independent events with probabilities $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, respectively. Compute $P(C_1 \cup C_2 \cup C_3)$.

1.4.24. From a bowl containing five red, three white, and seven blue chips, select four at random and without replacement. Compute the conditional probability of one red, zero white, and three blue chips, given that there are at least three blue chips in this sample of four chips.

1.4.25. Let the three mutually independent events C_1 , C_2 , and C_3 be such that $P(C_1) = P(C_2) = P(C_3) = \frac{1}{4}$. Find $P[(C_1^c \cap C_2^c) \cup C_3]$.

1.4.26. Each bag in a large box contains 25 tulip bulbs. It is known that 60% of the bags contain bulbs for 5 red and 20 yellow tulips, while the remaining 40% of the bags contain bulbs for 15 red and 10 yellow tulips. A bag is selected at random and a bulb taken at random from this bag is planted.

- (a) What is the probability that it will be a yellow tulip?
(b) Given that it is yellow, what is the conditional probability it comes from a bag that contained 5 red and 20 yellow bulbs?

1.4.27. The following game is played. The player randomly draws from the set of integers $\{1, 2, \dots, 20\}$. Let x denote the number drawn. Next the player draws at random from the set $\{x, \dots, 25\}$. If on this second draw, he draws a number greater than 21 he wins; otherwise, he loses.

- (a) Determine the sum that gives the probability that the player wins.
- (b) Write and run a line of R code that computes the probability that the player wins.
- (c) Write an R function that simulates the game and returns whether or not the player wins.
- (d) Do 10,000 simulations of your program in Part (c). Obtain the estimate and confidence interval, (1.4.7), for the probability that the player wins. Does your interval trap the true probability?

1.4.28. A bowl contains 10 chips numbered 1, 2, ..., 10, respectively. Five chips are drawn at random, one at a time, and without replacement. What is the probability that two even-numbered chips are drawn and they occur on even-numbered draws?

1.4.29. A person bets 1 dollar to b dollars that he can draw two cards from an ordinary deck of cards without replacement and that they will be of the same suit. Find b so that the bet is fair.

1.4.30 (Monte Hall Problem). Suppose there are three curtains. Behind one curtain there is a nice prize, while behind the other two there are worthless prizes. A contestant selects one curtain at random, and then Monte Hall opens one of the other two curtains to reveal a worthless prize. Hall then expresses the willingness to trade the curtain that the contestant has chosen for the other curtain that has not been opened. Should the contestant switch curtains or stick with the one that she has? To answer the question, determine the probability that she wins the prize if she switches.

1.4.31. A French nobleman, Chevalier de Méré, had asked a famous mathematician, Pascal, to explain why the following two probabilities were different (the difference had been noted from playing the game many times): (1) at least one six in four independent casts of a six-sided die; (2) at least a pair of sixes in 24 independent casts of a pair of dice. From proportions it seemed to de Méré that the probabilities should be the same. Compute the probabilities of (1) and (2).

1.4.32. Hunters A and B shoot at a target; the probabilities of hitting the target are p_1 and p_2 , respectively. Assuming independence, can p_1 and p_2 be selected so that

$$P(\text{zero hits}) = P(\text{one hit}) = P(\text{two hits})?$$

1.4.33. At the beginning of a study of individuals, 15% were classified as heavy smokers, 30% were classified as light smokers, and 55% were classified as nonsmokers. In the five-year study, it was determined that the death rates of the heavy and

light smokers were five and three times that of the nonsmokers, respectively. A randomly selected participant died over the five-year period: calculate the probability that the participant was a nonsmoker.

1.4.34. A chemist wishes to detect an impurity in a certain compound that she is making. There is a test that detects an impurity with probability 0.90; however, this test indicates that an impurity is there when it is not about 5% of the time. The chemist produces compounds with the impurity about 20% of the time. A compound is selected at random from the chemist's output. The test indicates that an impurity is present. What is the conditional probability that the compound actually has the impurity?

1.5 Random Variables

The reader perceives that a sample space \mathcal{C} may be tedious to describe if the elements of \mathcal{C} are not numbers. We now discuss how we may formulate a rule, or a set of rules, by which the elements c of \mathcal{C} may be represented by numbers. We begin the discussion with a very simple example. Let the random experiment be the toss of a coin and let the sample space associated with the experiment be $\mathcal{C} = \{H, T\}$, where H and T represent heads and tails, respectively. Let X be a function such that $X(T) = 0$ and $X(H) = 1$. Thus X is a real-valued function defined on the sample space \mathcal{C} which takes us from the sample space \mathcal{C} to a space of real numbers $\mathcal{D} = \{0, 1\}$. We now formulate the definition of a random variable and its space.

Definition 1.5.1. Consider a random experiment with a sample space \mathcal{C} . A function X , which assigns to each element $c \in \mathcal{C}$ one and only one number $X(c) = x$, is called a **random variable**. The **space** or **range** of X is the set of real numbers $\mathcal{D} = \{x : x = X(c), c \in \mathcal{C}\}$. ■

In this text, \mathcal{D} generally is a countable set or an interval of real numbers. We call random variables of the first type **discrete** random variables, while we call those of the second type **continuous** random variables. In this section, we present examples of discrete and continuous random variables and then in the next two sections we discuss them separately.

Given a random variable X , its range \mathcal{D} becomes the sample space of interest. Besides inducing the sample space \mathcal{D} , X also induces a probability which we call the **distribution** of X .

Consider first the case where X is a discrete random variable with a finite space $\mathcal{D} = \{d_1, \dots, d_m\}$. The only events of interest in the new sample space \mathcal{D} are subsets of \mathcal{D} . The induced probability distribution of X is also clear. Define the function $p_X(d_i)$ on \mathcal{D} by

$$p_X(d_i) = P[\{c : X(c) = d_i\}], \quad \text{for } i = 1, \dots, m. \quad (1.5.1)$$

In the next section, we formally define $p_X(d_i)$ as the **probability mass function** (**pmf**) of X . Then the induced probability distribution, $P_X(\cdot)$, of X is

$$P_X(D) = \sum_{d_i \in D} p_X(d_i), \quad D \subset \mathcal{D}.$$

As Exercise 1.5.11 shows, $P_X(D)$ is a probability on \mathcal{D} . An example is helpful here.

Example 1.5.1 (First Roll in the Game of Craps). Let X be the sum of the upfaces on a roll of a pair of fair 6-sided dice, each with the numbers 1 through 6 on it. The sample space is $\mathcal{C} = \{(i, j) : 1 \leq i, j \leq 6\}$. Because the dice are fair, $P[\{(i, j)\}] = 1/36$. The random variable X is $X(i, j) = i + j$. The space of X is $\mathcal{D} = \{2, \dots, 12\}$. By enumeration, the pmf of X is given by

Range value x	2	3	4	5	6	7	8	9	10	11	12
Probability $p_X(x)$	$\frac{1}{36}$	$\frac{2}{36}$	$\frac{3}{36}$	$\frac{4}{36}$	$\frac{5}{36}$	$\frac{6}{36}$	$\frac{5}{36}$	$\frac{4}{36}$	$\frac{3}{36}$	$\frac{2}{36}$	$\frac{1}{36}$

To illustrate the computation of probabilities concerning X , suppose $B_1 = \{x : x = 7, 11\}$ and $B_2 = \{x : x = 2, 3, 12\}$. Then, using the values of $p_X(x)$ given in the table,

$$\begin{aligned} P_X(B_1) &= \sum_{x \in B_1} p_X(x) = \frac{6}{36} + \frac{2}{36} = \frac{8}{36} \\ P_X(B_2) &= \sum_{x \in B_2} p_X(x) = \frac{1}{36} + \frac{2}{36} + \frac{1}{36} = \frac{4}{36}. \quad \blacksquare \end{aligned}$$

The second case is when X is a continuous random variable. In this case, \mathcal{D} is an interval of real numbers. In practice, continuous random variables are often measurements. For example, the weight of an adult is modeled by a continuous random variable. Here we would not be interested in the probability that a person weighs exactly 200 pounds, but we may be interested in the probability that a person weighs over 200 pounds. Generally, for the continuous random variables, the simple events of interest are intervals. We can usually determine a nonnegative function $f_X(x)$ such that for any interval of real numbers $(a, b) \in \mathcal{D}$, the induced probability distribution of X , $P_X(\cdot)$, is defined as

$$P_X[(a, b)] = P[\{c \in \mathcal{C} : a < X(c) < b\}] = \int_a^b f_X(x) dx; \quad (1.5.2)$$

that is, the probability that X falls between a and b is the area under the curve $y = f_X(x)$ between a and b . Besides $f_X(x) \geq 0$, we also require that $P_X(\mathcal{D}) = \int_{\mathcal{D}} f_X(x) dx = 1$ (total area under the curve over the sample space of X is 1). There are some technical issues in defining events in general for the space \mathcal{D} ; however, it can be shown that $P_X(D)$ is a probability on \mathcal{D} ; see Exercise 1.5.11. The function f_X is formally defined as the **probability density function (pdf)** of X in Section 1.7. An example is in order.

Example 1.5.2. For an example of a continuous random variable, consider the following simple experiment: choose a real number at random from the interval $(0, 1)$. Let X be the number chosen. In this case the space of X is $\mathcal{D} = (0, 1)$. It is not obvious as it was in the last example what the induced probability P_X is. But

there are some intuitive probabilities. For instance, because the number is chosen at random, it is reasonable to assign

$$P_X[(a, b)] = b - a, \text{ for } 0 < a < b < 1. \quad (1.5.3)$$

It follows that the pdf of X is

$$f_X(x) = \begin{cases} 1 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (1.5.4)$$

For example, the probability that X is less than an eighth or greater than seven eighths is

$$P\left[\left\{X < \frac{1}{8}\right\} \cup \left\{X > \frac{7}{8}\right\}\right] = \int_0^{\frac{1}{8}} dx + \int_{\frac{7}{8}}^1 dx = \frac{1}{4}.$$

Notice that a discrete probability model is not a possibility for this experiment. For any point a , $0 < a < 1$, we can choose n_0 so large such that $0 < a - n_0^{-1} < a < a + n_0^{-1} < 1$, i.e., $\{a\} \subset (a - n_0^{-1}, a + n_0^{-1})$. Hence,

$$P(X = a) \leq P\left(a - \frac{1}{n} < X < a + \frac{1}{n}\right) = \frac{2}{n}, \text{ for all } n \geq n_0. \quad (1.5.5)$$

Since $2/n \rightarrow 0$ as $n \rightarrow \infty$ and a is arbitrary, we conclude that $P(X = a) = 0$ for all $a \in (0, 1)$. Hence, the reasonable pdf, (1.5.4), for this model excludes a discrete probability model. ■

Remark 1.5.1. In equations (1.5.1) and (1.5.2), the subscript X on p_X and f_X identifies the pmf and pdf, respectively, with the random variable. We often use this notation, especially when there are several random variables in the discussion. On the other hand, if the identity of the random variable is clear, then we often suppress the subscripts. ■

The pmf of a discrete random variable and the pdf of a continuous random variable are quite different entities. The distribution function, though, uniquely determines the probability distribution of a random variable. It is defined by:

Definition 1.5.2 (Cumulative Distribution Function). *Let X be a random variable. Then its **cumulative distribution function** (cdf) is defined by $F_X(x)$, where*

$$F_X(x) = P_X((-\infty, x]) = P(\{c \in \mathcal{C} : X(c) \leq x\}). \quad (1.5.6)$$

As above, we shorten $P(\{c \in \mathcal{C} : X(c) \leq x\})$ to $P(X \leq x)$. Also, $F_X(x)$ is often called simply the distribution function (df). However, in this text, we use the modifier *cumulative* as $F_X(x)$ accumulates the probabilities less than or equal to x .

The next example discusses a cdf for a discrete random variable.

Example 1.5.3. Suppose we roll a fair die with the numbers 1 through 6 on it. Let X be the upface of the roll. Then the space of X is $\{1, 2, \dots, 6\}$ and its pmf is $p_X(i) = 1/6$, for $i = 1, 2, \dots, 6$. If $x < 1$, then $F_X(x) = 0$. If $1 \leq x < 2$, then $F_X(x) = 1/6$. Continuing this way, we see that the cdf of X is an increasing step function which steps up by $p_X(i)$ at each i in the space of X . The graph of F_X is given by Figure 1.5.1. Note that if we are given the cdf, then we can determine the pmf of X . ■

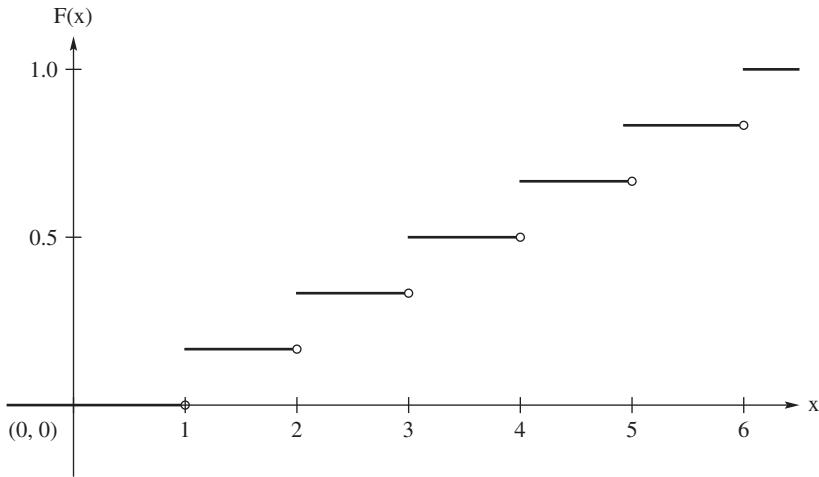

Figure 1.5.1: Distribution function for Example 1.5.3.

The following example discusses the cdf for the continuous random variable discussed in Example 1.5.2.

Example 1.5.4 (Continuation of Example 1.5.2). Recall that X denotes a real number chosen at random between 0 and 1. We now obtain the cdf of X . First, if $x < 0$, then $P(X \leq x) = 0$. Next, if $x \geq 1$, then $P(X \leq x) = 1$. Finally, if $0 < x < 1$, it follows from expression (1.5.3) that $P(X \leq x) = P(0 < X \leq x) = x - 0 = x$. Hence the cdf of X is

$$F_X(x) = \begin{cases} 0 & \text{if } x < 0 \\ x & \text{if } 0 \leq x < 1 \\ 1 & \text{if } x \geq 1. \end{cases} \quad (1.5.7)$$

A sketch of the cdf of X is given in Figure 1.5.2. Note, however, the connection between $F_X(x)$ and the pdf for this experiment $f_X(x)$, given in Example 1.5.2, is

$$F_X(x) = \int_{-\infty}^x f_X(t) dt, \quad \text{for all } x \in R,$$

and $\frac{d}{dx}F_X(x) = f_X(x)$, for all $x \in R$, except for $x = 0$ and $x = 1$. ■

Let X and Y be two random variables. We say that X and Y are **equal in distribution** and write $X \stackrel{D}{=} Y$ if and only if $F_X(x) = F_Y(x)$, for all $x \in R$. It is important to note while X and Y may be equal in distribution, they may be quite different. For instance, in the last example define the random variable Y as $Y = 1 - X$. Then $Y \neq X$. But the space of Y is the interval $(0, 1)$, the same as X . Further, the cdf of Y is 0 for $y < 0$; 1 for $y \geq 1$; and for $0 \leq y < 1$, it is

$$F_Y(y) = P(Y \leq y) = P(1 - X \leq y) = P(X \geq 1 - y) = 1 - (1 - y) = y.$$

Hence, Y has the same cdf as X , i.e., $Y \stackrel{D}{=} X$, but $Y \neq X$.

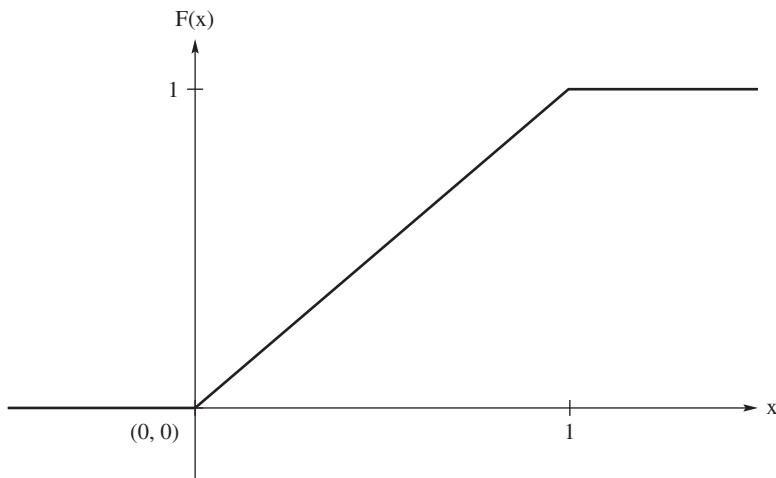

Figure 1.5.2: Distribution function for Example 1.5.4.

The cdfs displayed in Figures 1.5.1 and 1.5.2 show increasing functions with lower limits 0 and upper limits 1. In both figures, the cdfs are at least right continuous. As the next theorem proves, these properties are true in general for cdfs.

Theorem 1.5.1. *Let X be a random variable with cumulative distribution function $F(x)$. Then*

- (a) *For all a and b , if $a < b$, then $F(a) \leq F(b)$ (F is nondecreasing).*
- (b) $\lim_{x \rightarrow -\infty} F(x) = 0$ (*the lower limit of F is 0*).
- (c) $\lim_{x \rightarrow \infty} F(x) = 1$ (*the upper limit of F is 1*).
- (d) $\lim_{x \downarrow x_0} F(x) = F(x_0)$ (*F is right continuous*).

Proof: We prove parts (a) and (d) and leave parts (b) and (c) for Exercise 1.5.10.

Part (a): Because $a < b$, we have $\{X \leq a\} \subset \{X \leq b\}$. The result then follows from the monotonicity of P ; see Theorem 1.3.3.

Part (d): Let $\{x_n\}$ be any sequence of real numbers such that $x_n \downarrow x_0$. Let $C_n = \{X \leq x_n\}$. Then the sequence of sets $\{C_n\}$ is decreasing and $\cap_{n=1}^{\infty} C_n = \{X \leq x_0\}$. Hence, by Theorem 1.3.6,

$$\lim_{n \rightarrow \infty} F(x_n) = P\left(\bigcap_{n=1}^{\infty} C_n\right) = F(x_0),$$

which is the desired result. ■

The next theorem is helpful in evaluating probabilities using cdfs.

Theorem 1.5.2. *Let X be a random variable with the cdf F_X . Then for $a < b$, $P[a < X \leq b] = F_X(b) - F_X(a)$.*

Proof: Note that

$$\{-\infty < X \leq b\} = \{-\infty < X \leq a\} \cup \{a < X \leq b\}.$$

The proof of the result follows immediately because the union on the right side of this equation is a disjoint union. ■

Example 1.5.5. Let X be the lifetime in years of a mechanical part. Assume that X has the cdf

$$F_X(x) = \begin{cases} 0 & x < 0 \\ 1 - e^{-x} & 0 \leq x. \end{cases}$$

The pdf of X , $\frac{d}{dx}F_X(x)$, is

$$f_X(x) = \begin{cases} e^{-x} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Actually the derivative does not exist at $x = 0$, but in the continuous case the next theorem (1.5.3) shows that $P(X = 0) = 0$ and we can assign $f_X(0) = 0$ without changing the probabilities concerning X . The probability that a part has a lifetime between one and three years is given by

$$P(1 < X \leq 3) = F_X(3) - F_X(1) = \int_1^3 e^{-x} dx.$$

That is, the probability can be found by $F_X(3) - F_X(1)$ or evaluating the integral. In either case, it equals $e^{-1} - e^{-3} = 0.318$. ■

Theorem 1.5.1 shows that cdfs are right continuous and monotone. Such functions can be shown to have only a countable number of discontinuities. As the next theorem shows, the discontinuities of a cdf have mass; that is, if x is a point of discontinuity of F_X , then we have $P(X = x) > 0$.

Theorem 1.5.3. *For any random variable,*

$$P[X = x] = F_X(x) - F_X(x-), \quad (1.5.8)$$

for all $x \in R$, where $F_X(x-) = \lim_{z \uparrow x} F_X(z)$.

Proof: For any $x \in R$, we have

$$\{x\} = \bigcap_{n=1}^{\infty} \left(x - \frac{1}{n}, x \right];$$

that is, $\{x\}$ is the limit of a decreasing sequence of sets. Hence, by Theorem 1.3.6,

$$\begin{aligned} P[X = x] &= P \left[\bigcap_{n=1}^{\infty} \left\{ x - \frac{1}{n} < X \leq x \right\} \right] \\ &= \lim_{n \rightarrow \infty} P \left[x - \frac{1}{n} < X \leq x \right] \\ &= \lim_{n \rightarrow \infty} [F_X(x) - F_X(x - (1/n))] \\ &= F_X(x) - F_X(x-), \end{aligned}$$

which is the desired result. ■

Example 1.5.6. Let X have the discontinuous cdf

$$F_X(x) = \begin{cases} 0 & x < 0 \\ x/2 & 0 \leq x < 1 \\ 1 & 1 \leq x. \end{cases}$$

Then

$$P(-1 < X \leq 1/2) = F_X(1/2) - F_X(-1) = \frac{1}{4} - 0 = \frac{1}{4}$$

and

$$P(X = 1) = F_X(1) - F_X(1-) = 1 - \frac{1}{2} = \frac{1}{2}.$$

The value $1/2$ equals the value of the step of F_X at $x = 1$. ■

Since the total probability associated with a random variable X of the discrete type with pmf $p_X(x)$ or of the continuous type with pdf $f_X(x)$ is 1, then it must be true that

$$\sum_{x \in \mathcal{D}} p_X(x) = 1 \text{ and } \int_{\mathcal{D}} f_X(x) dx = 1,$$

where \mathcal{D} is the space of X . As the next two examples show, we can use this property to determine the pmf or pdf if we know the pmf or pdf down to a constant of proportionality.

Example 1.5.7. Suppose X has the pmf

$$p_X(x) = \begin{cases} cx & x = 1, 2, \dots, 10 \\ 0 & \text{elsewhere,} \end{cases}$$

for an appropriate constant c . Then

$$1 = \sum_{x=1}^{10} p_X(x) = \sum_{x=1}^{10} cx = c(1 + 2 + \dots + 10) = 55c,$$

and, hence, $c = 1/55$. ■

Example 1.5.8. Suppose X has the pdf

$$f_X(x) = \begin{cases} cx^3 & 0 < x < 2 \\ 0 & \text{elsewhere,} \end{cases}$$

for a constant c . Then

$$1 = \int_0^2 cx^3 dx = c \left[\frac{x^4}{4} \right]_0^2 = 4c,$$

and, hence, $c = 1/4$. For illustration of the computation of a probability involving X , we have

$$P\left(\frac{1}{4} < X < 1\right) = \int_{1/4}^1 \frac{x^3}{4} dx = \frac{255}{4096} = 0.06226. \blacksquare$$

EXERCISES

1.5.1. Let a card be selected from an ordinary deck of playing cards. The outcome c is one of these 52 cards. Let $X(c) = 4$ if c is an ace, let $X(c) = 3$ if c is a king, let $X(c) = 2$ if c is a queen, let $X(c) = 1$ if c is a jack, and let $X(c) = 0$ otherwise. Suppose that P assigns a probability of $\frac{1}{52}$ to each outcome c . Describe the induced probability $P_X(D)$ on the space $\mathcal{D} = \{0, 1, 2, 3, 4\}$ of the random variable X .

1.5.2. For each of the following, find the constant c so that $p(x)$ satisfies the condition of being a pmf of one random variable X .

(a) $p(x) = c(\frac{2}{3})^x$, $x = 1, 2, 3, \dots$, zero elsewhere.

(b) $p(x) = cx$, $x = 1, 2, 3, 4, 5, 6$, zero elsewhere.

1.5.3. Let $p_X(x) = x/15$, $x = 1, 2, 3, 4, 5$, zero elsewhere, be the pmf of X . Find $P(X = 1 \text{ or } 2)$, $P(\frac{1}{2} < X < \frac{5}{2})$, and $P(1 \leq X \leq 2)$.

1.5.4. Let $p_X(x)$ be the pmf of a random variable X . Find the cdf $F(x)$ of X and sketch its graph along with that of $p_X(x)$ if:

(a) $p_X(x) = 1$, $x = 0$, zero elsewhere.

(b) $p_X(x) = \frac{1}{3}$, $x = -1, 0, 1$, zero elsewhere.

(c) $p_X(x) = x/15$, $x = 1, 2, 3, 4, 5$, zero elsewhere.

1.5.5. Let us select five cards at random and without replacement from an ordinary deck of playing cards.

(a) Find the pmf of X , the number of hearts in the five cards.

(b) Determine $P(X \leq 1)$.

1.5.6. Let the probability set function of the random variable X be $P_X(D) = \int_D f(x) dx$, where $f(x) = 2x/9$, for $x \in \mathcal{D} = \{x : 0 < x < 3\}$. Define the events $D_1 = \{x : 0 < x < 1\}$ and $D_2 = \{x : 2 < x < 3\}$. Compute $P_X(D_1)$, $P_X(D_2)$, and $P_X(D_1 \cup D_2)$.

1.5.7. Let the space of the random variable X be $\mathcal{D} = \{x : 0 < x < 1\}$. If $D_1 = \{x : 0 < x < \frac{1}{2}\}$ and $D_2 = \{x : \frac{1}{2} \leq x < 1\}$, find $P_X(D_2)$ if $P_X(D_1) = \frac{1}{4}$.

1.5.8. Suppose the random variable X has the cdf

$$F(x) = \begin{cases} 0 & x < -1 \\ \frac{x+2}{4} & -1 \leq x < 1 \\ 1 & 1 \leq x. \end{cases}$$

Write an R function to sketch the graph of $F(x)$. Use your graph to obtain the probabilities: (a) $P(-\frac{1}{2} < X \leq \frac{1}{2})$; (b) $P(X = 0)$; (c) $P(X = 1)$; (d) $P(2 < X \leq 3)$.

1.5.9. Consider an urn that contains slips of paper each with one of the numbers $1, 2, \dots, 100$ on it. Suppose there are i slips with the number i on it for $i = 1, 2, \dots, 100$. For example, there are 25 slips of paper with the number 25. Assume that the slips are identical except for the numbers. Suppose one slip is drawn at random. Let X be the number on the slip.

- (a) Show that X has the pmf $p(x) = x/5050$, $x = 1, 2, 3, \dots, 100$, zero elsewhere.
- (b) Compute $P(X \leq 50)$.
- (c) Show that the cdf of X is $F(x) = [x](\lceil x \rceil + 1)/10100$, for $1 \leq x \leq 100$, where $[x]$ is the greatest integer in x .

1.5.10. Prove parts (b) and (c) of Theorem 1.5.1.

1.5.11. Let X be a random variable with space \mathcal{D} . For $D \subset \mathcal{D}$, recall that the probability induced by X is $P_X(D) = P[\{c : X(c) \in D\}]$. Show that $P_X(D)$ is a probability by showing the following:

- (a) $P_X(\mathcal{D}) = 1$.
- (b) $P_X(\mathcal{D}) \geq 0$.
- (c) For a sequence of sets $\{D_n\}$ in \mathcal{D} , show that

$$\{c : X(c) \in \cup_n D_n\} = \cup_n \{c : X(c) \in D_n\}.$$

- (d) Use part (c) to show that if $\{D_n\}$ is sequence of mutually exclusive events, then

$$P_X(\cup_{n=1}^{\infty} D_n) = \sum_{n=1}^{\infty} P_X(D_n).$$

Remark 1.5.2. In a probability theory course, we would show that the σ -field (collection of events) for \mathcal{D} is the smallest σ -field which contains all the open intervals of real numbers; see Exercise 1.3.24. Such a collection of events is sufficiently rich for discrete and continuous random variables. ■

1.6 Discrete Random Variables

The first example of a random variable encountered in the last section was an example of a discrete random variable, which is defined next.

Definition 1.6.1 (Discrete Random Variable). *We say a random variable is a discrete random variable if its space is either finite or countable.*

Example 1.6.1. Consider a sequence of independent flips of a coin, each resulting in a head (H) or a tail (T). Moreover, on each flip, we assume that H and T are equally likely; that is, $P(H) = P(T) = \frac{1}{2}$. The sample space \mathcal{C} consists of sequences like TTHTHHHT \dots . Let the random variable X equal the number of flips needed

to obtain the first head. Hence, $X(\text{TTHTHHT}\dots) = 3$. Clearly, the space of X is $\mathcal{D} = \{1, 2, 3, 4, \dots\}$. We see that $X = 1$ when the sequence begins with an H and thus $P(X = 1) = \frac{1}{2}$. Likewise, $X = 2$ when the sequence begins with TH, which has probability $P(X = 2) = (\frac{1}{2})(\frac{1}{2}) = \frac{1}{4}$ from the independence. More generally, if $X = x$, where $x = 1, 2, 3, 4, \dots$, there must be a string of $x - 1$ tails followed by a head; that is, TT \dots TH, where there are $x - 1$ tails in TT \dots T. Thus, from independence, we have a geometric sequence of probabilities, namely,

$$P(X = x) = \left(\frac{1}{2}\right)^{x-1} \left(\frac{1}{2}\right) = \left(\frac{1}{2}\right)^x, \quad x = 1, 2, 3, \dots, \quad (1.6.1)$$

the space of which is countable. An interesting event is that the first head appears on an odd number of flips; i.e., $X \in \{1, 3, 5, \dots\}$. The probability of this event is

$$P[X \in \{1, 3, 5, \dots\}] = \sum_{x=1}^{\infty} \left(\frac{1}{2}\right)^{2x-1} = \frac{1}{2} \sum_{x=1}^{\infty} \left(\frac{1}{4}\right)^{x-1} = \frac{1/2}{1 - (1/4)} = \frac{2}{3}. \blacksquare$$

As the last example suggests, probabilities concerning a discrete random variable can be obtained in terms of the probabilities $P(X = x)$, for $x \in \mathcal{D}$. These probabilities determine an important function, which we define as

Definition 1.6.2 (Probability Mass Function (pmf)). *Let X be a discrete random variable with space \mathcal{D} . The **probability mass function** (pmf) of X is given by*

$$p_X(x) = P[X = x], \quad \text{for } x \in \mathcal{D}. \quad (1.6.2)$$

Note that pmfs satisfy the following two properties:

$$(i) 0 \leq p_X(x) \leq 1, \quad x \in \mathcal{D}, \text{ and } (ii) \sum_{x \in \mathcal{D}} p_X(x) = 1. \quad (1.6.3)$$

In a more advanced class it can be shown that if a function satisfies properties (i) and (ii) for a discrete set \mathcal{D} , then this function uniquely determines the distribution of a random variable.

Let X be a discrete random variable with space \mathcal{D} . As Theorem 1.5.3 shows, discontinuities of $F_X(x)$ define a mass; that is, if x is a point of discontinuity of F_X , then $P(X = x) > 0$. We now make a distinction between the space of a discrete random variable and these points of positive probability. We define the **support** of a discrete random variable X to be the points in the space of X which have positive probability. We often use \mathcal{S} to denote the support of X . Note that $\mathcal{S} \subset \mathcal{D}$, but it may be that $\mathcal{S} = \mathcal{D}$.

Also, we can use Theorem 1.5.3 to obtain a relationship between the pmf and cdf of a discrete random variable. If $x \in \mathcal{S}$, then $p_X(x)$ is equal to the size of the discontinuity of F_X at x . If $x \notin \mathcal{S}$ then $P[X = x] = 0$ and, hence, F_X is continuous at this x .

Example 1.6.2. A lot, consisting of 100 fuses, is inspected by the following procedure. Five of these fuses are chosen at random and tested; if all five “blow” at the

correct amperage, the lot is accepted. If, in fact, there are 20 defective fuses in the lot, the probability of accepting the lot is, under appropriate assumptions,

$$\frac{\binom{80}{5}}{\binom{100}{5}} = 0.31931.$$

More generally, let the random variable X be the number of defective fuses among the five that are inspected. The pmf of X is given by

$$p_X(x) = \begin{cases} \frac{\binom{20}{x} \binom{80}{5-x}}{\binom{100}{5}} & \text{for } x = 0, 1, 2, 3, 4, 5 \\ 0 & \text{elsewhere.} \end{cases} \quad (1.6.4)$$

Clearly, the space of X is $\mathcal{D} = \{0, 1, 2, 3, 4, 5\}$, which is also its support. This is an example of a random variable of the discrete type whose distribution is an illustration of a **hypergeometric distribution**, which is formally defined in Chapter 3. Based on the above discussion, it is easy to graph the cdf of X ; see Exercise 1.6.5. ■

1.6.1 Transformations

A problem often encountered in statistics is the following. We have a random variable X and we know its distribution. We are interested, though, in a random variable Y which is some **transformation** of X , say, $Y = g(X)$. In particular, we want to determine the distribution of Y . Assume X is discrete with space \mathcal{D}_X . Then the space of Y is $\mathcal{D}_Y = \{g(x) : x \in \mathcal{D}_X\}$. We consider two cases.

In the first case, g is one-to-one. Then, clearly, the pmf of Y is obtained as

$$p_Y(y) = P[Y = y] = P[g(X) = y] = P[X = g^{-1}(y)] = p_X(g^{-1}(y)). \quad (1.6.5)$$

Example 1.6.3. Consider the random variable X of Example 1.6.1. Recall that X was the flip number on which the first head appeared. Let Y be the number of flips before the first head. Then $Y = X - 1$. In this case, the function g is $g(x) = x - 1$, whose inverse is given by $g^{-1}(y) = y + 1$. The space of Y is $\mathcal{D}_Y = \{0, 1, 2, \dots\}$. The pmf of X is given by (1.6.1); hence, based on expression (1.6.5), the pmf of Y is

$$p_Y(y) = p_X(y+1) = \left(\frac{1}{2}\right)^{y+1}, \quad \text{for } y = 0, 1, 2, \dots. \quad \blacksquare$$

Example 1.6.4. Let X have the pmf

$$p_X(x) = \begin{cases} \frac{3!}{x!(3-x)!} \left(\frac{2}{3}\right)^x \left(\frac{1}{3}\right)^{3-x} & x = 0, 1, 2, 3 \\ 0 & \text{elsewhere.} \end{cases}$$

We seek the pmf $p_Y(y)$ of the random variable $Y = X^2$. The transformation $y = g(x) = x^2$ maps $\mathcal{D}_X = \{x : x = 0, 1, 2, 3\}$ onto $\mathcal{D}_Y = \{y : y = 0, 1, 4, 9\}$. In general, $y = x^2$ does not define a one-to-one transformation; here, however, it does,

for there are no negative values of x in $\mathcal{D}_X = \{x : x = 0, 1, 2, 3\}$. That is, we have the single-valued inverse function $x = g^{-1}(y) = \sqrt{y}$ (not $-\sqrt{y}$), and so

$$p_Y(y) = p_X(\sqrt{y}) = \frac{3!}{(\sqrt{y})!(3 - \sqrt{y})!} \left(\frac{2}{3}\right)^{\sqrt{y}} \left(\frac{1}{3}\right)^{3 - \sqrt{y}}, \quad y = 0, 1, 4, 9. \blacksquare$$

The second case is where the transformation, $g(x)$, is not one-to-one. Instead of developing an overall rule, for most applications involving discrete random variables the pmf of Y can be obtained in a straightforward manner. We offer two examples as illustrations.

Consider the geometric random variable in Example 1.6.3. Suppose we are playing a game against the “house” (say, a gambling casino). If the first head appears on an odd number of flips, we pay the house one dollar, while if it appears on an even number of flips, we win one dollar from the house. Let Y denote our net gain. Then the space of Y is $\{-1, 1\}$. In Example 1.6.1, we showed that the probability that X is odd is $\frac{2}{3}$. Hence, the distribution of Y is given by $p_Y(-1) = 2/3$ and $p_Y(1) = 1/3$.

As a second illustration, let $Z = (X - 2)^2$, where X is the geometric random variable of Example 1.6.1. Then the space of Z is $\mathcal{D}_Z = \{0, 1, 4, 9, 16, \dots\}$. Note that $Z = 0$ if and only if $X = 2$; $Z = 1$ if and only if $X = 1$ or $X = 3$; while for the other values of the space there is a one-to-one correspondence given by $x = \sqrt{z} + 2$, for $z \in \{4, 9, 16, \dots\}$. Hence, the pmf of Z is

$$p_Z(z) = \begin{cases} p_X(2) = \frac{1}{4} & \text{for } z = 0 \\ p_X(1) + p_X(3) = \frac{5}{8} & \text{for } z = 1 \\ p_X(\sqrt{z} + 2) = \frac{1}{4} \left(\frac{1}{2}\right)^{\sqrt{z}} & \text{for } z = 4, 9, 16, \dots \end{cases} \quad (1.6.6)$$

For verification, the reader is asked to show in Exercise 1.6.11 that the pmf of Z sums to 1 over its space.

EXERCISES

1.6.1. Let X equal the number of heads in four independent flips of a coin. Using certain assumptions, determine the pmf of X and compute the probability that X is equal to an odd number.

1.6.2. Let a bowl contain 10 chips of the same size and shape. One and only one of these chips is red. Continue to draw chips from the bowl, one at a time and at random and without replacement, until the red chip is drawn.

- (a) Find the pmf of X , the number of trials needed to draw the red chip.
- (b) Compute $P(X \leq 4)$.

1.6.3. Cast a die a number of independent times until a six appears on the up side of the die.

- (a) Find the pmf $p(x)$ of X , the number of casts needed to obtain that first six.

- (b) Show that $\sum_{x=1}^{\infty} p(x) = 1$.
- (c) Determine $P(X = 1, 3, 5, 7, \dots)$.
- (d) Find the cdf $F(x) = P(X \leq x)$.

1.6.4. Cast a die two independent times and let X equal the absolute value of the difference of the two resulting values (the numbers on the up sides). Find the pmf of X . *Hint:* It is not necessary to find a formula for the pmf.

1.6.5. For the random variable X defined in Example 1.6.2:

- (a) Write an R function that returns the pmf. Note that in R, `choose(m,k)` computes $\binom{m}{k}$.
- (b) Write an R function that returns the graph of the cdf.

1.6.6. For the random variable X defined in Example 1.6.1, graph the cdf of X .

1.6.7. Let X have a pmf $p(x) = \frac{1}{3}$, $x = 1, 2, 3$, zero elsewhere. Find the pmf of $Y = 2X + 1$.

1.6.8. Let X have the pmf $p(x) = (\frac{1}{2})^x$, $x = 1, 2, 3, \dots$, zero elsewhere. Find the pmf of $Y = X^3$.

1.6.9. Let X have the pmf $p(x) = 1/3$, $x = -1, 0, 1$. Find the pmf of $Y = X^2$.

1.6.10. Let X have the pmf

$$p(x) = \left(\frac{1}{2}\right)^{|x|}, \quad x = -1, -2, -3, \dots$$

Find the pmf of $Y = X^4$.

1.6.11. Show that the function given in expression (1.6.6) is a pmf.

1.7 Continuous Random Variables

In the last section, we discussed discrete random variables. Another class of random variables important in statistical applications is the class of continuous random variables, which we define next.

Definition 1.7.1 (Continuous Random Variables). *We say a random variable is a continuous random variable if its cumulative distribution function $F_X(x)$ is a continuous function for all $x \in R$.*

Recall from Theorem 1.5.3 that $P(X = x) = F_X(x) - F_X(x-)$, for any random variable X . Hence, for a continuous random variable X , there are no points of discrete mass; i.e., if X is continuous, then $P(X = x) = 0$ for all $x \in R$. Most continuous random variables are **absolutely continuous**; that is,

$$F_X(x) = \int_{-\infty}^x f_X(t) dt, \tag{1.7.1}$$

for some function $f_X(t)$. The function $f_X(t)$ is called a **probability density function** (pdf) of X . If $f_X(x)$ is also continuous, then the Fundamental Theorem of Calculus implies that

$$\frac{d}{dx} F_X(x) = f_X(x). \quad (1.7.2)$$

The **support** of a continuous random variable X consists of all points x such that $f_X(x) > 0$. As in the discrete case, we often denote the support of X by \mathcal{S} .

If X is a continuous random variable, then probabilities can be obtained by integration; i.e.,

$$P(a < X \leq b) = F_X(b) - F_X(a) = \int_a^b f_X(t) dt.$$

Also, for continuous random variables,

$$P(a < X \leq b) = P(a \leq X \leq b) = P(a \leq X < b) = P(a < X < b).$$

From the definition (1.7.2), note that pdfs satisfy the two properties

$$(i) \ f_X(x) \geq 0 \text{ and } (ii) \ \int_{-\infty}^{\infty} f_X(t) dt = 1. \quad (1.7.3)$$

The second property, of course, follows from $F_X(\infty) = 1$. In an advanced course in probability, it is shown that if a function satisfies the above two properties, then it is a pdf for a continuous random variable; see, for example, Tucker (1967).

Recall in Example 1.5.2 the simple experiment where a number was chosen at random from the interval $(0, 1)$. The number chosen, X , is an example of a continuous random variable. Recall that the cdf of X is $F_X(x) = x$, for $0 < x < 1$. Hence, the pdf of X is given by

$$f_X(x) = \begin{cases} 1 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (1.7.4)$$

Any continuous or discrete random variable X whose pdf or pmf is constant on the support of X is said to have a **uniform** distribution; see Chapter 3 for a more formal definition.

Example 1.7.1 (Point Chosen at Random Within the Unit Circle). Suppose we select a point at random in the interior of a circle of radius 1. Let X be the distance of the selected point from the origin. The sample space for the experiment is $\mathcal{C} = \{(w, y) : w^2 + y^2 < 1\}$. Because the point is chosen at random, it seems that subsets of \mathcal{C} which have equal area are equilikely. Hence, the probability of the selected point lying in a set $A \subset \mathcal{C}$ is proportional to the area of A ; i.e.,

$$P(A) = \frac{\text{area of } A}{\pi}.$$

For $0 < x < 1$, the event $\{X \leq x\}$ is equivalent to the point lying in a circle of radius x . By this probability rule, $P(X \leq x) = \pi x^2 / \pi = x^2$; hence, the cdf of X is

$$F_X(x) = \begin{cases} 0 & x < 0 \\ x^2 & 0 \leq x < 1 \\ 1 & 1 \leq x. \end{cases} \quad (1.7.5)$$

Taking the derivative of $F_X(x)$, we obtain the pdf of X :

$$f_X(x) = \begin{cases} 2x & 0 \leq x < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (1.7.6)$$

For illustration, the probability that the selected point falls in the ring with radii $1/4$ and $1/2$ is given by

$$P\left(\frac{1}{4} < X \leq \frac{1}{2}\right) = \int_{\frac{1}{4}}^{\frac{1}{2}} 2w dw = w^2 \Big|_{\frac{1}{4}}^{\frac{1}{2}} = \frac{3}{16}. \blacksquare$$

Example 1.7.2. Let the random variable be the time in seconds between incoming telephone calls at a busy switchboard. Suppose that a reasonable probability model for X is given by the pdf

$$f_X(x) = \begin{cases} \frac{1}{4}e^{-x/4} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Note that f_X satisfies the two properties of a pdf, namely, (i) $f(x) \geq 0$ and (ii)

$$\int_0^\infty \frac{1}{4}e^{-x/4} dx = -e^{-x/4} \Big|_0^\infty = 1.$$

For illustration, the probability that the time between successive phone calls exceeds 4 seconds is given by

$$P(X > 4) = \int_4^\infty \frac{1}{4}e^{-x/4} dx = e^{-1} = 0.3679.$$

The pdf and the probability of interest are depicted in Figure 1.7.1. From the figure, the pdf has a long right tail and no left tail. We say that this distribution is **skewed right** or positively skewed. This is an example of a gamma distribution which is discussed in detail in Chapter 3. ■

1.7.1 Quantiles

Quantiles (percentiles) are easily interpretable characteristics of a distribution.

Definition 1.7.2 (Quantile). *Let $0 < p < 1$. The quantile of order p of the distribution of a random variable X is a value ξ_p such that $P(X < \xi_p) \leq p$ and $P(X \leq \xi_p) \geq p$. It is also known as the $(100p)$ th percentile of X .* ■

Examples include the **median** which is the quantile $\xi_{1/2}$. The median is also called the second quartile. It is a point in the domain of X that divides the mass of the pdf into its lower and upper halves. The first and third quartiles divide each of these halves into quarters. They are, respectively $\xi_{1/4}$ and $\xi_{3/4}$. We label these quartiles as q_1, q_2 and q_3 , respectively. The difference $iq = q_3 - q_1$ is called the

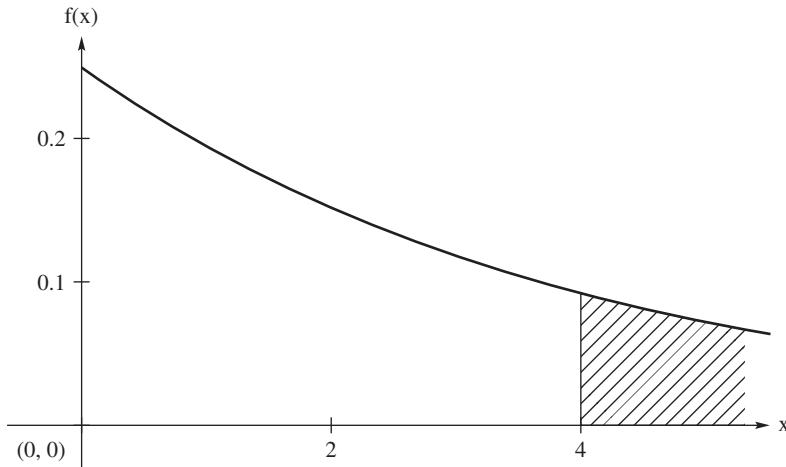

Figure 1.7.1: In Example 1.7.2, the area under the pdf to the right of 4 is $P(X > 4)$.

interquartile range of X . The median is often used as a measure of center of the distribution of X , while the interquartile range is used as a measure of **spread** or **dispersion** of the distribution of X .

Quantiles need not be unique even for continuous random variables with pdfs. For example, any point in the interval $(2, 3)$ serves as a median for the following pdf:

$$f(x) = \begin{cases} 3(1-x)(x-2) & 1 < x < 2 \\ 3(3-x)(x-4) & 3 < x < 4 \\ 0 & \text{elsewhere.} \end{cases} \quad (1.7.7)$$

If, however, a quantile, say ξ_p , is in the support of an absolutely continuous random variable X with cdf $F_X(x)$ then ξ_p is the unique solution to the equation:

$$\xi_p = F_X^{-1}(p), \quad (1.7.8)$$

where $F_X^{-1}(u)$ is the inverse function of $F_X(x)$. The next example serves as an illustration.

Example 1.7.3. Let X be a continuous random variable with pdf

$$f(x) = \frac{e^x}{(1 + 5e^x)^{1.2}}, \quad -\infty < x < \infty. \quad (1.7.9)$$

This pdf is a member of the log F -family of distributions which is often used in the modeling of the log of lifetime data. Note that X has the support space $(-\infty, \infty)$. The cdf of X is

$$F(x) = 1 - (1 + 5e^{-x})^{-2}, \quad -\infty < x < \infty,$$

which is confirmed immediately by showing that $F'(x) = f(x)$. For the inverse of the cdf, set $u = F(x)$ and solve for u . A few steps of algebra lead to

$$F^{-1}(u) = \log \{ .2 [(1-u)^{-5} - 1] \}, \quad 0 < u < 1.$$

Thus, $\xi_p = F_X^{-1}(p) = \log \{ .2 [(1-p)^{-5} - 1] \}$. The following three R functions can be used to compute the pdf, cdf, and inverse cdf of F , respectively. These can be downloaded at the site listed in the Preface.

```
dlogF <- function(x){exp(x)/(1+5*exp(x))^(1.2)}
plogF <- function(x){1- (1+5*exp(x))^{(-.2)}}
qlogF <- function(x){log(.2*((1-x)^{(-5)} - 1))}
```

Once the R function `qlogF` is sourced, it can be used to compute quantiles. The following is an R script which results in the computation of the three quartiles of X :

```
qlogF(.25) ; qlogF(.50); qlogF(.75)
-0.4419242; 1.824549; 5.321057
```

Figure 1.7.2 displays a plot of this pdf and its quartiles. Notice that this is another example of a skewed-right distribution; i.e., the right-tail is much longer than left-tail. In terms of the log-lifetime of mechanical parts having this distribution, it follows that 50% of the parts survive beyond 1.83 log-units and 25% of the parts live longer than 5.32 log-units. With the long-right tail, some parts attain a long life. ■

1.7.2 Transformations

Let X be a continuous random variable with a known pdf f_X . As in the discrete case, we are often interested in the distribution of a random variable Y which is some **transformation** of X , say, $Y = g(X)$. Often we can obtain the pdf of Y by first obtaining its cdf. We illustrate this with two examples.

Example 1.7.4. Let X be the random variable in Example 1.7.1. Recall that X was the distance from the origin to the random point selected in the unit circle. Suppose instead that we are interested in the square of the distance; that is, let $Y = X^2$. The support of Y is the same as that of X , namely, $\mathcal{S}_Y = (0, 1)$. What is the cdf of Y ? By expression (1.7.5), the cdf of X is

$$F_X(x) = \begin{cases} 0 & x < 0 \\ x^2 & 0 \leq x < 1 \\ 1 & 1 \leq x. \end{cases} \quad (1.7.10)$$

Let y be in the support of Y ; i.e., $0 < y < 1$. Then, using expression (1.7.10) and the fact that the support of X contains only positive numbers, the cdf of Y is

$$F_Y(y) = P(Y \leq y) = P(X^2 \leq y) = P(X \leq \sqrt{y}) = F_X(\sqrt{y}) = \sqrt{y}^2 = y.$$

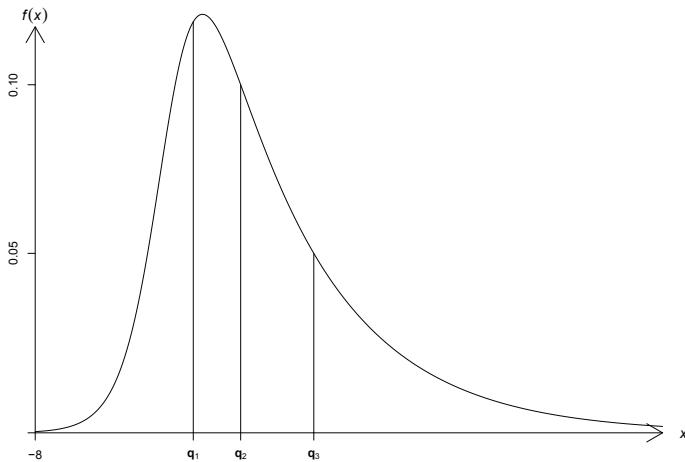

Figure 1.7.2: A graph of the pdf (1.7.9) showing the three quartiles, q_1, q_2 , and q_3 , of the distribution. The probability mass in each of the four sections is $1/4$.

It follows that the pdf of Y is

$$f_Y(y) = \begin{cases} 1 & 0 < y < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad \blacksquare$$

Example 1.7.5. Let $f_X(x) = \frac{1}{2}$, $-1 < x < 1$, zero elsewhere, be the pdf of a random variable X . Note that X has a uniform distribution with the interval of support $(-1, 1)$. Define the random variable Y by $Y = X^2$. We wish to find the pdf of Y . If $y \geq 0$, the probability $P(Y \leq y)$ is equivalent to

$$P(X^2 \leq y) = P(-\sqrt{y} \leq X \leq \sqrt{y}).$$

Accordingly, the cdf of Y , $F_Y(y) = P(Y \leq y)$, is given by

$$F_Y(y) = \begin{cases} 0 & y < 0 \\ \int_{-\sqrt{y}}^{\sqrt{y}} \frac{1}{2} dx = \sqrt{y} & 0 \leq y < 1 \\ 1 & 1 \leq y. \end{cases}$$

Hence, the pdf of Y is given by

$$f_Y(y) = \begin{cases} \frac{1}{2\sqrt{y}} & 0 < y < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad \blacksquare$$

These examples illustrate the **cumulative distribution function technique**. The transformation in Example 1.7.4 is one-to-one, and in such cases we can obtain

a simple formula for the pdf of Y in terms of the pdf of X , which we record in the next theorem.

Theorem 1.7.1. *Let X be a continuous random variable with pdf $f_X(x)$ and support \mathcal{S}_X . Let $Y = g(X)$, where $g(x)$ is a one-to-one differentiable function, on the support of X , \mathcal{S}_X . Denote the inverse of g by $x = g^{-1}(y)$ and let $dx/dy = d[g^{-1}(y)]/dy$. Then the pdf of Y is given by*

$$f_Y(y) = f_X(g^{-1}(y)) \left| \frac{dx}{dy} \right|, \quad \text{for } y \in \mathcal{S}_Y, \quad (1.7.11)$$

where the support of Y is the set $\mathcal{S}_Y = \{y = g(x) : x \in \mathcal{S}_X\}$.

Proof: Since $g(x)$ is one-to-one and continuous, it is either strictly monotonically increasing or decreasing. Assume that it is strictly monotonically increasing, for now. The cdf of Y is given by

$$F_Y(y) = P[Y \leq y] = P[g(X) \leq y] = P[X \leq g^{-1}(y)] = F_X(g^{-1}(y)). \quad (1.7.12)$$

Hence, the pdf of Y is

$$f_Y(y) = \frac{d}{dy} F_Y(y) = f_X(g^{-1}(y)) \frac{dx}{dy}, \quad (1.7.13)$$

where dx/dy is the derivative of the function $x = g^{-1}(y)$. In this case, because g is increasing, $dx/dy > 0$. Hence, we can write $dx/dy = |dx/dy|$.

Suppose $g(x)$ is strictly monotonically decreasing. Then (1.7.12) becomes $F_Y(y) = 1 - F_X(g^{-1}(y))$. Hence, the pdf of Y is $f_Y(y) = f_X(g^{-1}(y))(-dx/dy)$. But since g is decreasing, $dx/dy < 0$ and, hence, $-dx/dy = |dx/dy|$. Thus Equation (1.7.11) is true in both cases.⁵ ■

Henceforth, we refer to $dx/dy = (d/dy)g^{-1}(y)$ as the **Jacobian** (denoted by J) of the transformation. In most mathematical areas, $J = dx/dy$ is referred to as the Jacobian of the inverse transformation $x = g^{-1}(y)$, but in this book it is called the Jacobian of the transformation, simply for convenience.

We summarize Theorem 1.7.1 in a simple algorithm which we illustrate in the next example. Assuming that the transformation $Y = g(X)$ is one-to-one, the following steps lead to the pdf of Y :

1. Find the support of Y .
2. Solve for the inverse of the transformation; i.e., solve for x in terms of y in $y = g(x)$, thereby obtaining $x = g^{-1}(y)$.
3. Obtain $\frac{dx}{dy}$.
4. The pdf of Y is $f_Y(y) = f_X(g^{-1}(y)) \left| \frac{dx}{dy} \right|$.

⁵The proof of Theorem 1.7.1 can also be obtained by using the change-of-variable technique as discussed in Chapter 4 of *Mathematical Comments*.

Example 1.7.6. Let X have the pdf

$$f(x) = \begin{cases} 4x^3 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Consider the random variable $Y = -\log X$. Here are the steps of the above algorithm:

1. The support of $Y = -\log X$ is $(0, \infty)$.
2. If $y = -\log x$ then $x = e^{-y}$.
3. $\frac{dx}{dy} = -e^{-y}$.
4. Thus the pdf of Y is:

$$f_Y(y) = f_X(e^{-y}) | -e^{-y} | = 4(e^{-y})^3 e^{-y} = 4e^{-4y}.$$

1.7.3 Mixtures of Discrete and Continuous Type Distributions

We close this section by two examples of distributions that are not of the discrete or the continuous type.

Example 1.7.7. Let a distribution function be given by

$$F(x) = \begin{cases} 0 & x < 0 \\ \frac{x+1}{2} & 0 \leq x < 1 \\ 1 & 1 \leq x. \end{cases}$$

Then, for instance,

$$P\left(-3 < X \leq \frac{1}{2}\right) = F\left(\frac{1}{2}\right) - F(-3) = \frac{3}{4} - 0 = \frac{3}{4}$$

and

$$P(X = 0) = F(0) - F(0-) = \frac{1}{2} - 0 = \frac{1}{2}.$$

The graph of $F(x)$ is shown in Figure 1.7.3. We see that $F(x)$ is not always continuous, nor is it a step function. Accordingly, the corresponding distribution is neither of the continuous type nor of the discrete type. It may be described as a **mixture** of those types. ■

Distributions that are mixtures of the continuous and discrete type do, in fact, occur frequently in practice. For illustration, in life testing, suppose we know that the length of life, say X , exceeds the number b , but the exact value of X is unknown. This is called *censoring*. For instance, this can happen when a subject in a cancer study simply disappears; the investigator knows that the subject has lived a certain number of months, but the exact length of life is unknown. Or it might happen when an investigator does not have enough time in an investigation to observe the moments of deaths of all the animals, say rats, in some study. Censoring can also occur in the insurance industry; in particular, consider a loss with a limited-pay policy in which the top amount is exceeded but it is not known by how much.

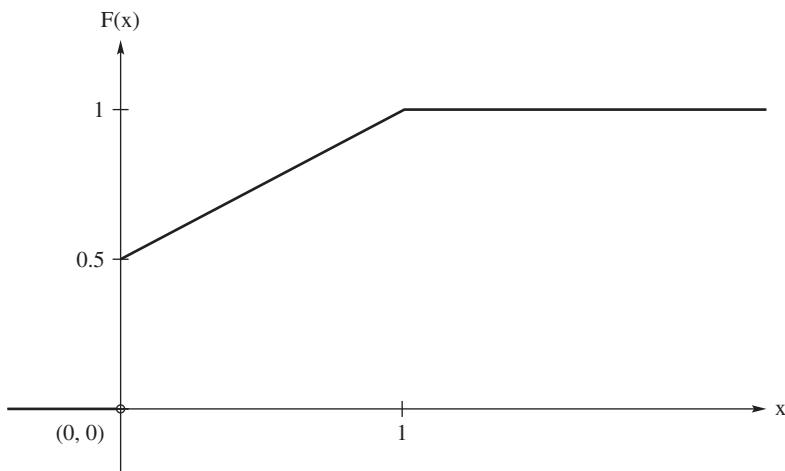

Figure 1.7.3: Graph of the cdf of Example 1.7.7.

Example 1.7.8. Reinsurance companies are concerned with large losses because they might agree, for illustration, to cover losses due to wind damages that are between \$2,000,000 and \$10,000,000. Say that X equals the size of a wind loss in millions of dollars, and suppose it has the cdf

$$F_X(x) = \begin{cases} 0 & -\infty < x < 0 \\ 1 - \left(\frac{10}{10+x}\right)^3 & 0 \leq x < \infty. \end{cases}$$

If losses beyond \$10,000,000 are reported only as 10, then the cdf of this censored distribution is

$$F_Y(y) = \begin{cases} 0 & -\infty < y < 0 \\ 1 - \left(\frac{10}{10+y}\right)^3 & 0 \leq y < 10, \\ 1 & 10 \leq y < \infty, \end{cases}$$

which has a jump of $[10/(10+10)]^3 = \frac{1}{8}$ at $y = 10$. ■

EXERCISES

1.7.1. Let a point be selected from the sample space $\mathcal{C} = \{c : 0 < c < 10\}$. Let $C \subset \mathcal{C}$ and let the probability set function be $P(C) = \int_C \frac{1}{10} dz$. Define the random variable X to be $X(c) = c^2$. Find the cdf and the pdf of X .

1.7.2. Let the space of the random variable X be $\mathcal{C} = \{x : 0 < x < 10\}$ and let $P_X(C_1) = \frac{3}{8}$, where $C_1 = \{x : 1 < x < 5\}$. Show that $P_X(C_2) \leq \frac{5}{8}$, where $C_2 = \{x : 5 \leq x < 10\}$.

1.7.3. Let the subsets $C_1 = \{\frac{1}{4} < x < \frac{1}{2}\}$ and $C_2 = \{\frac{1}{2} \leq x < 1\}$ of the space $\mathcal{C} = \{x : 0 < x < 1\}$ of the random variable X be such that $P_X(C_1) = \frac{1}{8}$ and $P_X(C_2) = \frac{1}{2}$. Find $P_X(C_1 \cup C_2)$, $P_X(C_1^c)$, and $P_X(C_1^c \cap C_2^c)$.

1.7.4. Given $\int_C [1/\pi(1+x^2)] dx$, where $C \subset \mathcal{C} = \{x : -\infty < x < \infty\}$. Show that the integral could serve as a probability set function of a random variable X whose space is \mathcal{C} .

1.7.5. Let the probability set function of the random variable X be

$$P_X(C) = \int_C e^{-x} dx, \quad \text{where } \mathcal{C} = \{x : 0 < x < \infty\}.$$

Let $C_k = \{x : 2 - 1/k < x \leq 3\}$, $k = 1, 2, 3, \dots$. Find the limits $\lim_{k \rightarrow \infty} C_k$ and $P_X(\lim_{k \rightarrow \infty} C_k)$. Find $P_X(C_k)$ and show that $\lim_{k \rightarrow \infty} P_X(C_k) = P_X(\lim_{k \rightarrow \infty} C_k)$.

1.7.6. For each of the following pdfs of X , find $P(|X| < 1)$ and $P(X^2 < 9)$.

(a) $f(x) = x^2/18$, $-3 < x < 3$, zero elsewhere.

(b) $f(x) = (x+2)/18$, $-2 < x < 4$, zero elsewhere.

1.7.7. Let $f(x) = 1/x^2$, $1 < x < \infty$, zero elsewhere, be the pdf of X . If $C_1 = \{x : 1 < x < 2\}$ and $C_2 = \{x : 4 < x < 5\}$, find $P_X(C_1 \cup C_2)$ and $P_X(C_1 \cap C_2)$.

1.7.8. A **mode** of the distribution of a random variable X is a value of x that maximizes the pdf or pmf. If there is only one such x , it is called the *mode of the distribution*. Find the mode of each of the following distributions:

(a) $p(x) = (\frac{1}{2})^x$, $x = 1, 2, 3, \dots$, zero elsewhere.

(b) $f(x) = 12x^2(1-x)$, $0 < x < 1$, zero elsewhere.

(c) $f(x) = (\frac{1}{2})x^2e^{-x}$, $0 < x < \infty$, zero elsewhere.

1.7.9. The median and quantiles, in general, are discussed in Section 1.7.1. Find the median of each of the following distributions:

(a) $p(x) = \frac{4!}{x!(4-x)!}(\frac{1}{4})^x(\frac{3}{4})^{4-x}$, $x = 0, 1, 2, 3, 4$, zero elsewhere.

(b) $f(x) = 3x^2$, $0 < x < 1$, zero elsewhere.

(c) $f(x) = \frac{1}{\pi(1+x^2)}$, $-\infty < x < \infty$.

1.7.10. Let $0 < p < 1$. Find the 0.20 quantile (20th percentile) of the distribution that has pdf $f(x) = 4x^3$, $0 < x < 1$, zero elsewhere.

1.7.11. For each of the following cdfs $F(x)$, find the pdf $f(x)$ [pmf in part (d)], the first quartile, and the 0.60 quantile. Also, sketch the graphs of $f(x)$ and $F(x)$. May use R to obtain the graphs. For Part(a) the code is provided.

(a) $F(x) = \frac{1}{2} + \frac{1}{\pi}\tan^{-1}(x)$, $-\infty < x < \infty$.

```
x<-seq(-5,5,.01); y<-.5+atan(x)/pi; y2<-1/(pi*(1+x^2))
par(mfrow=c(1,2));plot(y~x);plot(y2~x)
```

(b) $F(x) = \exp\{-e^{-x}\}$, $-\infty < x < \infty$.

(c) $F(x) = (1 + e^{-x})^{-1}$, $-\infty < x < \infty$.

(d) $F(x) = \sum_{j=1}^x \left(\frac{1}{2}\right)^j$.

1.7.12. Find the cdf $F(x)$ associated with each of the following probability density functions. Sketch the graphs of $f(x)$ and $F(x)$.

(a) $f(x) = 3(1 - x)^2$, $0 < x < 1$, zero elsewhere.

(b) $f(x) = 1/x^2$, $1 < x < \infty$, zero elsewhere.

(c) $f(x) = \frac{1}{3}$, $0 < x < 1$ or $2 < x < 4$, zero elsewhere.

Also, find the median and the 25th percentile of each of these distributions.

1.7.13. Consider the cdf $F(x) = 1 - e^{-x} - xe^{-x}$, $0 \leq x < \infty$, zero elsewhere. Find the pdf, the mode, and the median (by numerical methods) of this distribution.

1.7.14. Let X have the pdf $f(x) = 2x$, $0 < x < 1$, zero elsewhere. Compute the probability that X is at least $\frac{3}{4}$ given that X is at least $\frac{1}{2}$.

1.7.15. The random variable X is said to be **stochastically larger** than the random variable Y if

$$P(X > z) \geq P(Y > z), \quad (1.7.14)$$

for all real z , with strict inequality holding for at least one z value. Show that this requires that the cdfs enjoy the following property:

$$F_X(z) \leq F_Y(z),$$

for all real z , with strict inequality holding for at least one z value.

1.7.16. Let X be a continuous random variable with support $(-\infty, \infty)$. Consider the random variable $Y = X + \Delta$, where $\Delta > 0$. Using the definition in Exercise 1.7.15, show that Y is stochastically larger than X .

1.7.17. Divide a line segment into two parts by selecting a point at random. Find the probability that the length of the larger segment is at least three times the length of the shorter segment. Assume a uniform distribution.

1.7.18. Let X be the number of gallons of ice cream that is requested at a certain store on a hot summer day. Assume that $f(x) = 12x(1000-x)^2/10^{12}$, $0 < x < 1000$, zero elsewhere, is the pdf of X . How many gallons of ice cream should the store have on hand each of these days, so that the probability of exhausting its supply on a particular day is 0.05?

1.7.19. Find the 25th percentile of the distribution having pdf $f(x) = |x|/4$, where $-2 < x < 2$ and zero elsewhere.

1.7.20. The distribution of the random variable X in Example 1.7.3 is often used to model the log of the lifetime of a mechanical or electrical part. What about the lifetime itself? Let $Y = \exp\{X\}$.

- (a) Determine the range of Y .
- (b) Use the transformation technique to find the pdf of Y .
- (c) Write an R function to compute this pdf and use it to obtain a graph of the pdf. Discuss the plot.
- (d) Determine the 90th percentile of Y .

1.7.21. The distribution of the random variable X in Example 1.7.3 is a member of the log- F family. Another member has the cdf

$$F(x) = \left[1 + \frac{2}{3}e^{-x}\right]^{-5/2}, \quad -\infty < x < \infty.$$

- (a) Determine the corresponding pdf.
- (b) Write an R function that computes this cdf. Plot the function and obtain approximations of the quartiles and median by inspection of the plot.
- (c) Obtain the inverse of the cdf and confirm the percentiles in Part (b).

1.7.22. Let X have the pdf $f(x) = x^2/9$, $0 < x < 3$, zero elsewhere. Find the pdf of $Y = X^3$.

1.7.23. If the pdf of X is $f(x) = 2xe^{-x^2}$, $0 < x < \infty$, zero elsewhere, determine the pdf of $Y = X^2$.

1.7.24. Let X have the uniform pdf $f_X(x) = \frac{1}{\pi}$, for $-\frac{\pi}{2} < x < \frac{\pi}{2}$. Find the pdf of $Y = \tan X$. This is the pdf of a **Cauchy distribution**.

1.7.25. Let X have the pdf $f(x) = 4x^3$, $0 < x < 1$, zero elsewhere. Find the cdf and the pdf of $Y = -\ln X^4$.

1.7.26. Let $f(x) = \frac{1}{3}$, $-1 < x < 2$, zero elsewhere, be the pdf of X . Find the cdf and the pdf of $Y = X^2$.

Hint: Consider $P(X^2 \leq y)$ for two cases: $0 \leq y < 1$ and $1 \leq y < 4$.

1.8 Expectation of a Random Variable

In this section we introduce the expectation operator, which we use throughout the remainder of the text. For the definition, recall from calculus that absolute convergence of sums or integrals implies their convergence.

Definition 1.8.1 (Expectation). Let X be a random variable. If X is a continuous random variable with pdf $f(x)$ and

$$\int_{-\infty}^{\infty} |x| f(x) dx < \infty,$$

then the **expectation** of X is

$$E(X) = \int_{-\infty}^{\infty} x f(x) dx.$$

If X is a discrete random variable with pmf $p(x)$ and

$$\sum_x |x| p(x) < \infty,$$

then the **expectation** of X is

$$E(X) = \sum_x x p(x).$$

Sometimes the expectation $E(X)$ is called the **mathematical expectation** of X , the **expected value** of X , or the **mean** of X . When the mean designation is used, we often denote the $E(X)$ by μ ; i.e., $\mu = E(X)$.

Example 1.8.1 (Expectation of a Constant). Consider a constant random variable, that is, a random variable with all its mass at a constant k . This is a discrete random variable with pmf $p(k) = 1$. We have by definition that

$$E(k) = kp(k) = k. \quad \blacksquare \quad (1.8.1)$$

Example 1.8.2. Let the random variable X of the discrete type have the pmf given by the table

x	1	2	3	4
$p(x)$	$\frac{4}{10}$	$\frac{1}{10}$	$\frac{3}{10}$	$\frac{2}{10}$

Here $p(x) = 0$ if x is not equal to one of the first four positive integers. This illustrates the fact that there is no need to have a formula to describe a pmf. We have

$$E(X) = (1) \left(\frac{4}{10} \right) + (2) \left(\frac{1}{10} \right) + (3) \left(\frac{3}{10} \right) + (4) \left(\frac{2}{10} \right) = \frac{23}{10} = 2.3. \quad \blacksquare$$

Example 1.8.3. Let the continuous random variable X have the pdf

$$f(x) = \begin{cases} 4x^3 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then

$$E(X) = \int_0^1 x(4x^3) dx = \int_0^1 4x^4 dx = \frac{4x^5}{5} \Big|_0^1 = \frac{4}{5}. \quad \blacksquare$$

Remark 1.8.1. The terminology of expectation or expected value has its origin in games of chance. For example, consider a game involving a spinner with the numbers 1, 2, 3 and 4 on it. Suppose the corresponding probabilities of spinning these numbers are 0.20, 0.30, 0.35, and 0.15. To begin a game, a player pays \$5 to the “house” to play. The spinner is then spun and the player “wins” the amount in the second line of the table:

Number spun x	1	2	3	4
“Wins”	\$2	\$3	\$4	\$12
$G = \text{Gain}$	-\$3	-\$2	-\$1	\$7
$p_G(x)$	0.20	0.30	0.35	0.15

“Wins” is in quotes, since the player must pay \$5 to play. Of course, the random variable of interest is the gain to the player; i.e., G with the range as given in the third row of the table. Notice that 20% of the time the player gains -\$3; 30% of the time the player gains -\$2; 35% of the time the player gains -\$1; and 15% of the time the player gains \$7. In mathematics this sentence is expressed as

$$(-3) \times 0.20 + (-2) \times 0.30 + (-1) \times 0.35 + 7 \times 0.15 = -0.50,$$

which, of course, is $E(G)$. That is, the expected gain to the player in this game is $-\$0.50$. So the player expects to lose 50 cents per play. We say a game is a **fair game**, if the expected gain is 0. So this spinner game is not a fair game. ■

Let us consider a function of a random variable X . Call this function $Y = g(X)$. Because Y is a random variable, we could obtain its expectation by first finding the distribution of Y . However, as the following theorem states, we can use the distribution of X to determine the expectation of Y .

Theorem 1.8.1. *Let X be a random variable and let $Y = g(X)$ for some function g .*

- (a) *Suppose X is continuous with pdf $f_X(x)$. If $\int_{-\infty}^{\infty} |g(x)|f_X(x) dx < \infty$, then the expectation of Y exists and it is given by*

$$E(Y) = \int_{-\infty}^{\infty} g(x)f_X(x) dx. \quad (1.8.2)$$

- (b) *Suppose X is discrete with pmf $p_X(x)$. Suppose the support of X is denoted by \mathcal{S}_X . If $\sum_{x \in \mathcal{S}_X} |g(x)|p_X(x) < \infty$, then the expectation of Y exists and it is given by*

$$E(Y) = \sum_{x \in \mathcal{S}_X} g(x)p_X(x). \quad (1.8.3)$$

Proof: We give the proof in the discrete case. The proof for the continuous case requires some advanced results in analysis; see, also, Exercise 1.8.1.

Because $\sum_{x \in \mathcal{S}_X} |g(x)|p_X(x)$ converges, it follows by a theorem in calculus⁶ that any rearrangement of the terms of the series converges to the same limit. Thus we have,

$$\sum_{x \in \mathcal{S}_X} |g(x)|p_X(x) = \sum_{y \in \mathcal{S}_Y} \sum_{\{x \in \mathcal{S}_X : g(x)=y\}} |g(x)|p_X(x) \quad (1.8.4)$$

$$= \sum_{y \in \mathcal{S}_Y} |y| \sum_{\{x \in \mathcal{S}_X : g(x)=y\}} p_X(x) \quad (1.8.5)$$

$$= \sum_{y \in \mathcal{S}_Y} |y|p_Y(y), \quad (1.8.6)$$

where \mathcal{S}_Y denotes the support of Y . So $E(Y)$ exists; i.e., $\sum_{x \in \mathcal{S}_X} g(x)p_X(x)$ converges. Because $\sum_{x \in \mathcal{S}_X} g(x)p_X(x)$ converges and also converges absolutely, the same theorem from calculus can be used to show that the above equations (1.8.4)–(1.8.6) hold without the absolute values. Hence, $E(Y) = \sum_{x \in \mathcal{S}_X} g(x)p_X(x)$, which is the desired result. ■

The following two examples illustrate this theorem.

Example 1.8.4. Let Y be the discrete random variable discussed in Example 1.6.3 and let $Z = e^{-Y}$. Since $(2e)^{-1} < 1$, we have by Theorem 1.8.1 that

$$\begin{aligned} E[Z] &= E[e^{-Y}] = \sum_{y=0}^{\infty} e^{-y} \left(\frac{1}{2}\right)^{y+1} \\ &= e \sum_{y=0}^{\infty} \left(\frac{1}{2}e^{-1}\right)^{y+1} = \frac{e}{1 - (1/(2e))} = \frac{2e^2}{2e - 1}. \blacksquare \end{aligned}$$

Example 1.8.5. Let X be a continuous random variable with the pdf $f(x) = 2x$ which has support on the interval $(0, 1)$. Suppose $Y = 1/(1+X)$. Then by Theorem 1.8.1, we have

$$E(Y) = \int_0^1 \frac{2x}{1+x} dx = \int_1^2 \frac{2u-2}{u} du = 2(1 - \log 2),$$

where we have used the change in variable $u = 1 + x$ in the second integral. ■

Theorem 1.8.2 shows that the expectation operator E is a linear operator.

Theorem 1.8.2. *Let $g_1(X)$ and $g_2(X)$ be functions of a random variable X . Suppose the expectations of $g_1(X)$ and $g_2(X)$ exist. Then for any constants k_1 and k_2 , the expectation of $k_1g_1(X) + k_2g_2(X)$ exists and it is given by*

$$E[k_1g_1(X) + k_2g_2(X)] = k_1E[g_1(X)] + k_2E[g_2(X)]. \quad (1.8.7)$$

⁶For example, see Chapter 2 on infinite series in *Mathematical Comments*, referenced in the Preface.

Proof: For the continuous case, existence follows from the hypothesis, the triangle inequality, and the linearity of the integral; i.e.,

$$\begin{aligned} \int_{-\infty}^{\infty} |k_1 g_1(x) + k_2 g_2(x)| f_X(x) dx &\leq |k_1| \int_{-\infty}^{\infty} |g_1(x)| f_X(x) dx \\ &\quad + |k_2| \int_{-\infty}^{\infty} |g_2(x)| f_X(x) dx < \infty. \end{aligned}$$

The result (1.8.7) follows similarly using the linearity of the integral. The proof for the discrete case follows likewise using the linearity of sums. ■

The following examples illustrate these theorems.

Example 1.8.6. Let X have the pdf

$$f(x) = \begin{cases} 2(1-x) & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then

$$\begin{aligned} E(X) &= \int_{-\infty}^{\infty} x f(x) dx = \int_0^1 (x) 2(1-x) dx = \frac{1}{3}, \\ E(X^2) &= \int_{-\infty}^{\infty} x^2 f(x) dx = \int_0^1 (x^2) 2(1-x) dx = \frac{1}{6}, \end{aligned}$$

and, of course,

$$E(6X + 3X^2) = 6\left(\frac{1}{3}\right) + 3\left(\frac{1}{6}\right) = \frac{5}{2}. \blacksquare$$

Example 1.8.7. Let X have the pmf

$$p(x) = \begin{cases} \frac{x}{6} & x = 1, 2, 3 \\ 0 & \text{elsewhere.} \end{cases}$$

Then

$$E(6X^3 + X) = 6E(X^3) + E(X) = 6 \sum_{x=1}^3 x^3 p(x) + \sum_{x=1}^3 x p(x) = \frac{301}{3}. \blacksquare$$

Example 1.8.8. Let us divide, at random, a horizontal line segment of length 5 into two parts. If X is the length of the left-hand part, it is reasonable to assume that X has the pdf

$$f(x) = \begin{cases} \frac{1}{5} & 0 < x < 5 \\ 0 & \text{elsewhere.} \end{cases}$$

The expected value of the length of X is $E(X) = \frac{5}{2}$ and the expected value of the length $5 - x$ is $E(5 - x) = \frac{5}{2}$. But the expected value of the product of the two lengths is equal to

$$E[X(5 - X)] = \int_0^5 x(5 - x)\left(\frac{1}{5}\right) dx = \frac{25}{6} \neq \left(\frac{5}{2}\right)^2.$$

That is, in general, the expected value of a product is not equal to the product of the expected values. ■

1.8.1 R Computation for an Estimation of the Expected Gain

In the following example, we use an R function to estimate the expected gain in a simple game.

Example 1.8.9. Consider the following game. A player pays p_0 to play. He then rolls a fair 6-sided die with the numbers 1 through 6 on it. If the upface is a 1 or a 2, then the game is over. Otherwise, he flips a fair coin. If the coin toss results in a tail, he receives \$1 and the game is over. If, on the other hand, the coin toss results in a head, he draws 2 cards without replacement from a standard deck of 52 cards. If none of the cards is an ace, he receives \$2, while he receives \$10 or \$50 if gets 1 or 2 aces, respectively. In both cases, the game is over. Let G denote the player's gain. To determine the expected gain, we need the distribution of G . The support of G is the set $\{-p_0, 1 - p_0, 2 - p_0, 10 - p_0, 50 - p_0\}$. For the associated probabilities we need the distribution of X , where X is the number of aces in a draw of 2 cards from a standard deck of 52 cards without replacement. This is another example of the hypergeometric distribution discussed in Example 1.6.2. For our situation, the distribution is

$$P(X = x) = \frac{\binom{4}{x} \binom{48}{2-x}}{\binom{52}{2}}, \quad x = 0, 1, 2.$$

Using this formula, the probabilities of X , to 4 places, are 0.8507, 0.1448, and 0.0045 for x equal to 0, 1, and 2, respectively. Using these probabilities and independence, the distribution and expected value of G can be determined; see Exercise 1.8.13. Suppose, however, a person does not have this expertise. Such a person would observe the game a number of times and then use the average of the observed gains as his/her estimate of $E(G)$. We will show in Chapter 2 that this estimate, in a probability sense, is close to $E(G)$, as the number of times the game is played increases. To compute this estimation, we use the following R function, `simplegame`, which plays the game and returns the gain. This function can be downloaded at the site given in the Preface. The argument of the function is the amount the player pays to play. Also, the third line of the function computes the distribution of the above random variable X . To draw from a discrete distribution, the code makes use of the R function `sample` which was discussed previously in Example 1.4.12.

```
simplegame <- function(amtpaid){
    gain <- -amtpaid
    x <- 0:2; pace <- (choose(4,x)*choose(48,2-x))/choose(52,2)
    x <- sample(1:6,1,prob=rep(1/6,6))
    if(x > 2){
        y <- sample(0:1,1,prob=rep(1/2,2))
        if(y==0){
            gain <- gain + 1
        } else {
            z <- sample(0:2,1,prob=pace)
            if(z==0){gain <- gain + 2}
            if(z==1){gain <- gain + 10}
            if(z==2){gain <- gain + 50}
        }
    }
}
```

```

        }
    }
    return(gain)
}

```

The following R script obtains the average gain for a sample of 10,000 games. For the example, we set the amount the player pays at \$5.

```

amtpaid <- 5; numtimes <- 10000; gains <- c()
for(i in 1:numtimes){gains <- c(gains,simplegame(amtpaid))}
mean(gains)

```

When we ran this script, we obtained -3.5446 as our estimate of $E(G)$. Exercise 1.8.13 shows that $E(G) = -3.54$. ■

EXERCISES

1.8.1. Our proof of Theorem 1.8.1 was for the discrete case. The proof for the continuous case requires some advanced results in analysis. If, in addition, though, the function $g(x)$ is one-to-one, show that the result is true for the continuous case.
Hint: First assume that $y = g(x)$ is strictly increasing. Then use the change-of-variable technique with Jacobian dx/dy on the integral $\int_{x \in S_X} g(x)f_X(x) dx$.

1.8.2. Consider the random variable X in Example 1.8.5. As in the example, let $Y = 1/(1 + X)$. In the example we found the $E(Y)$ by using Theorem 1.8.1. Verify this result by finding the pdf of Y and use it to obtain the $E(Y)$.

1.8.3. Let X have the pdf $f(x) = (x + 2)/18$, $-2 < x < 4$, zero elsewhere. Find $E(X)$, $E[(X + 2)^3]$, and $E[6X - 2(X + 2)^3]$.

1.8.4. Suppose that $p(x) = \frac{1}{5}$, $x = 1, 2, 3, 4, 5$, zero elsewhere, is the pmf of the discrete-type random variable X . Compute $E(X)$ and $E(X^2)$. Use these two results to find $E[(X + 2)^2]$ by writing $(X + 2)^2 = X^2 + 4X + 4$.

1.8.5. Let X be a number selected at random from a set of numbers $\{51, 52, \dots, 100\}$. Approximate $E(1/X)$.

Hint: Find reasonable upper and lower bounds by finding integrals bounding $E(1/X)$.

1.8.6. Let the pmf $p(x)$ be positive at $x = -1, 0, 1$ and zero elsewhere.

(a) If $p(0) = \frac{1}{4}$, find $E(X^2)$.

(b) If $p(0) = \frac{1}{4}$ and if $E(X) = \frac{1}{4}$, determine $p(-1)$ and $p(1)$.

1.8.7. Let X have the pdf $f(x) = 3x^2$, $0 < x < 1$, zero elsewhere. Consider a random rectangle whose sides are X and $(1 - X)$. Determine the expected value of the area of the rectangle.

1.8.8. A bowl contains 10 chips, of which 8 are marked \$2 each and 2 are marked \$5 each. Let a person choose, at random and without replacement, three chips from this bowl. If the person is to receive the sum of the resulting amounts, find his expectation.

1.8.9. Let $f(x) = 2x$, $0 < x < 1$, zero elsewhere, be the pdf of X .

- (a) Compute $E(1/X)$.
- (b) Find the cdf and the pdf of $Y = 1/X$.
- (c) Compute $E(Y)$ and compare this result with the answer obtained in part (a).

1.8.10. Two distinct integers are chosen at random and without replacement from the first six positive integers. Compute the expected value of the absolute value of the difference of these two numbers.

1.8.11. Let X have a Cauchy distribution which has the pdf

$$f(x) = \frac{1}{\pi} \frac{1}{x^2 + 1}, \quad -\infty < x < \infty. \quad (1.8.8)$$

Then X is symmetrically distributed about 0 (why?). Why isn't $E(X) = 0$?

1.8.12. Let X have the pdf $f(x) = 3x^2$, $0 < x < 1$, zero elsewhere.

- (a) Compute $E(X^3)$.
- (b) Show that $Y = X^3$ has a uniform(0, 1) distribution.
- (c) Compute $E(Y)$ and compare this result with the answer obtained in part (a).

1.8.13. Using the probabilities discussed in Example 1.8.9 and independence, determine the distribution of the random variable G , the gain to a player of the game when he pays p_0 dollars to play. Show that $E(G) = -\$3.54$ if the player pays \$5 to play.

1.8.14. A bowl contains five chips, which cannot be distinguished by a sense of touch alone. Three of the chips are marked \$1 each and the remaining two are marked \$4 each. A player is blindfolded and draws, at random and without replacement, two chips from the bowl. The player is paid an amount equal to the sum of the values of the two chips that he draws and the game is over. Suppose it costs p_0 dollars to play the game. Let the random variable G be the gain to a player of the game. Determine the distribution of G and the $E(G)$. Determine p_0 so that the game is fair. The R code `sample(c(1,1,1,4,4), 2)` computes a sample for this game. Expand this into an R function that simulates the game.

1.9 Some Special Expectations

Certain expectations, if they exist, have special names and symbols to represent them. First, let X be a random variable of the discrete type with pmf $p(x)$. Then

$$E(X) = \sum_x xp(x).$$

If the support of X is $\{a_1, a_2, a_3, \dots\}$, it follows that

$$E(X) = a_1 p(a_1) + a_2 p(a_2) + a_3 p(a_3) + \dots.$$

This sum of products is seen to be a “weighted average” of the values of a_1, a_2, a_3, \dots , the “weight” associated with each a_i being $p(a_i)$. This suggests that we call $E(X)$ the arithmetic mean of the values of X , or, more simply, the **mean value** of X (or the mean value of the distribution).

Definition 1.9.1 (Mean). *Let X be a random variable whose expectation exists. The mean value μ of X is defined to be $\mu = E(X)$.*

The mean is the first moment (about 0) of a random variable. Another special expectation involves the second moment. Let X be a discrete random variable with support $\{a_1, a_2, \dots\}$ and with pmf $p(x)$, then

$$\begin{aligned} E[(X - \mu)^2] &= \sum_x (x - \mu)^2 p(x) \\ &= (a_1 - \mu)^2 p(a_1) + (a_2 - \mu)^2 p(a_2) + \dots. \end{aligned}$$

This sum of products may be interpreted as a “weighted average” of the squares of the deviations of the numbers a_1, a_2, \dots from the mean value μ of those numbers where the “weight” associated with each $(a_i - \mu)^2$ is $p(a_i)$. It can also be thought of as the second moment of X about μ . This is an important expectation for all types of random variables, and we usually refer to it as the **variance** of X .

Definition 1.9.2 (Variance). *Let X be a random variable with finite mean μ and such that $E[(X - \mu)^2]$ is finite. Then the variance of X is defined to be $E[(X - \mu)^2]$. It is usually denoted by σ^2 or by $\text{Var}(X)$.*

It is worthwhile to observe that $\text{Var}(X)$ equals

$$\sigma^2 = E[(X - \mu)^2] = E(X^2 - 2\mu X + \mu^2).$$

Because E is a linear operator it then follows that

$$\begin{aligned} \sigma^2 &= E(X^2) - 2\mu E(X) + \mu^2 \\ &= E(X^2) - 2\mu^2 + \mu^2 \\ &= E(X^2) - \mu^2. \end{aligned}$$

This frequently affords an easier way of computing the variance of X .

It is customary to call σ (the positive square root of the variance) the **standard deviation** of X (or the standard deviation of the distribution). The number σ is sometimes interpreted as a measure of the dispersion of the points of the space relative to the mean value μ . If the space contains only one point k for which $p(k) > 0$, then $p(k) = 1$, $\mu = k$, and $\sigma = 0$.

While the variance is not a linear operator, it does satisfy the following result:

Theorem 1.9.1. *Let X be a random variable with finite mean μ and variance σ^2 . Then for all constants a and b ,*

$$\text{Var}(aX + b) = a^2 \text{Var}(X). \quad (1.9.1)$$

Proof. Because E is linear, $E(aX + b) = a\mu + b$. Hence, by definition

$$\text{Var}(aX + b) = E\{(aX + b) - (a\mu + b)\}^2 = E\{a^2[X - \mu]^2\} = a^2\text{Var}(X).$$

■

Based on this theorem, for standard deviations, $\sigma_{aX+b} = |a|\sigma_X$. The following example illustrates these points.

Example 1.9.1. Suppose the random variable X has a uniform distribution, (1.7.4), with pdf $f_X(x) = 1/(2a)$, $-a < x < a$, zero elsewhere. Then the mean and variance of X are:

$$\begin{aligned}\mu &= \int_{-a}^a x \frac{1}{2a} dx = \frac{1}{2a} \left. \frac{x^2}{2} \right|_{-a}^a = 0, \\ \sigma^2 &= \int_{-a}^a x^2 \frac{1}{2a} dx = \frac{1}{2a} \left. \frac{x^3}{3} \right|_{-a}^a = \frac{a^2}{3}.\end{aligned}$$

so that $\sigma_X = a/\sqrt{3}$ is the standard deviation of the distribution of X . Consider the transformation $Y = 2X$. Because the inverse transformation is $x = y/2$ and $dx/dy = 1/2$, it follows from Theorem 1.7.1 that the pdf of Y is $f_Y(y) = 1/4a$, $-2a < y < 2a$, zero elsewhere. Based on the above discussion, $\sigma_Y = (2a)/\sqrt{3}$. Hence, the standard deviation of Y is twice that of X , reflecting the fact that the probability for Y is spread out twice as much (relative to the mean zero) as the probability for X . ■

Example 1.9.2. Let X have the pdf

$$f(x) = \begin{cases} \frac{1}{2}(x+1) & -1 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then the mean value of X is

$$\mu = \int_{-\infty}^{\infty} xf(x) dx = \int_{-1}^1 x \frac{x+1}{2} dx = \frac{1}{3},$$

while the variance of X is

$$\sigma^2 = \int_{-\infty}^{\infty} x^2 f(x) dx - \mu^2 = \int_{-1}^1 x^2 \frac{x+1}{2} dx - \left(\frac{1}{3}\right)^2 = \frac{2}{9}. \quad \blacksquare$$

Example 1.9.3. If X has the pdf

$$f(x) = \begin{cases} \frac{1}{x^2} & 1 < x < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

then the mean value of X does not exist, because

$$\int_1^\infty |x| \frac{1}{x^2} dx = \lim_{b \rightarrow \infty} \int_1^b \frac{1}{x} dx = \lim_{b \rightarrow \infty} (\log b - \log 1) = \infty,$$

which is not finite. ■

We next define a third special expectation.

Definition 1.9.3 (Moment Generating Function). *Let X be a random variable such that for some $h > 0$, the expectation of e^{tX} exists for $-h < t < h$. The moment generating function of X is defined to be the function $M(t) = E(e^{tX})$, for $-h < t < h$. We use the abbreviation mgf to denote the moment generating function of a random variable.*

Actually, all that is needed is that the mgf exists in an open neighborhood of 0. Such an interval, of course, includes an interval of the form $(-h, h)$ for some $h > 0$. Further, it is evident that if we set $t = 0$, we have $M(0) = 1$. But note that for an mgf to exist, it must exist in an open interval about 0.

Example 1.9.4. Suppose we have a fair spinner with the numbers 1, 2, and 3 on it. Let X be the number of spins until the first 3 occurs. Assuming that the spins are independent, the pmf of X is

$$p(x) = \frac{1}{3} \left(\frac{2}{3}\right)^{x-1}, \quad x = 1, 2, 3, \dots$$

Then, using the geometric series, the mgf of X is

$$M(t) = E(e^{tX}) = \sum_{x=1}^{\infty} e^{tx} \frac{1}{3} \left(\frac{2}{3}\right)^{x-1} = \frac{1}{3} e^t \sum_{x=1}^{\infty} \left(e^t \frac{2}{3}\right)^{x-1} = \frac{1}{3} e^t \left(1 - e^t \frac{2}{3}\right)^{-1},$$

provided that $e^t(2/3) < 1$; i.e., $t < \log(3/2)$. This last interval is an open interval of 0; hence, the mgf of X exists and is given in the final line of the above derivation. ■

If we are discussing several random variables, it is often useful to subscript M as M_X to denote that this is the mgf of X .

Let X and Y be two random variables with mgfs. If X and Y have the same distribution, i.e., $F_X(z) = F_Y(z)$ for all z , then certainly $M_X(t) = M_Y(t)$ in a neighborhood of 0. But one of the most important properties of mgfs is that the converse of this statement is true too. That is, mgfs uniquely identify distributions. We state this as a theorem. The proof of this converse, though, is beyond the scope of this text; see Chung (1974). We verify it for a discrete situation.

Theorem 1.9.2. Let X and Y be random variables with moment generating functions M_X and M_Y , respectively, existing in open intervals about 0. Then $F_X(z) = F_Y(z)$ for all $z \in R$ if and only if $M_X(t) = M_Y(t)$ for all $t \in (-h, h)$ for some $h > 0$.

Because of the importance of this theorem, it does seem desirable to try to make the assertion plausible. This can be done if the random variable is of the discrete type. For example, let it be given that

$$M(t) = \frac{1}{10}e^t + \frac{2}{10}e^{2t} + \frac{3}{10}e^{3t} + \frac{4}{10}e^{4t}$$

is, for all real values of t , the mgf of a random variable X of the discrete type. If we let $p(x)$ be the pmf of X with support $\{a_1, a_2, a_3, \dots\}$, then because

$$M(t) = \sum_x e^{tx} p(x),$$

we have

$$\frac{1}{10}e^t + \frac{2}{10}e^{2t} + \frac{3}{10}e^{3t} + \frac{4}{10}e^{4t} = p(a_1)e^{a_1 t} + p(a_2)e^{a_2 t} + \dots$$

Because this is an identity for all real values of t , it seems that the right-hand member should consist of but four terms and that each of the four should be equal, respectively, to one of those in the left-hand member; hence we may take $a_1 = 1$, $p(a_1) = \frac{1}{10}$; $a_2 = 2$, $p(a_2) = \frac{2}{10}$; $a_3 = 3$, $p(a_3) = \frac{3}{10}$; $a_4 = 4$, $p(a_4) = \frac{4}{10}$. Or, more simply, the pmf of X is

$$p(x) = \begin{cases} \frac{x}{10} & x = 1, 2, 3, 4 \\ 0 & \text{elsewhere.} \end{cases}$$

On the other hand, suppose X is a random variable of the continuous type. Let it be given that

$$M(t) = \frac{1}{1-t}, \quad t < 1,$$

is the mgf of X . That is, we are given

$$\frac{1}{1-t} = \int_{-\infty}^{\infty} e^{tx} f(x) dx, \quad t < 1.$$

It is not at all obvious how $f(x)$ is found. However, it is easy to see that a distribution with pdf

$$f(x) = \begin{cases} e^{-x} & 0 < x < \infty \\ 0 & \text{elsewhere} \end{cases}$$

has the mgf $M(t) = (1-t)^{-1}$, $t < 1$. Thus the random variable X has a distribution with this pdf in accordance with the assertion of the uniqueness of the mgf.

Since a distribution that has an mgf $M(t)$ is completely determined by $M(t)$, it would not be surprising if we could obtain some properties of the distribution directly from $M(t)$. For example, the existence of $M(t)$ for $-h < t < h$ implies that derivatives of $M(t)$ of all orders exist at $t = 0$. Also, a theorem in analysis allows

us to interchange the order of differentiation and integration (or summation in the discrete case). That is, if X is continuous,

$$M'(t) = \frac{dM(t)}{dt} = \frac{d}{dt} \int_{-\infty}^{\infty} e^{tx} f(x) dx = \int_{-\infty}^{\infty} \frac{d}{dt} e^{tx} f(x) dx = \int_{-\infty}^{\infty} x e^{tx} f(x) dx.$$

Likewise, if X is a discrete random variable,

$$M'(t) = \frac{dM(t)}{dt} = \sum_x x e^{tx} p(x).$$

Upon setting $t = 0$, we have in either case

$$M'(0) = E(X) = \mu.$$

The second derivative of $M(t)$ is

$$M''(t) = \int_{-\infty}^{\infty} x^2 e^{tx} f(x) dx \quad \text{or} \quad \sum_x x^2 e^{tx} p(x),$$

so that $M''(0) = E(X^2)$. Accordingly, $\text{Var}(X)$ equals

$$\sigma^2 = E(X^2) - \mu^2 = M''(0) - [M'(0)]^2.$$

For example, if $M(t) = (1-t)^{-1}$, $t < 1$, as in the illustration above, then

$$M'(t) = (1-t)^{-2} \quad \text{and} \quad M''(t) = 2(1-t)^{-3}.$$

Hence

$$\mu = M'(0) = 1$$

and

$$\sigma^2 = M''(0) - \mu^2 = 2 - 1 = 1.$$

Of course, we could have computed μ and σ^2 from the pdf by

$$\mu = \int_{-\infty}^{\infty} x f(x) dx \quad \text{and} \quad \sigma^2 = \int_{-\infty}^{\infty} x^2 f(x) dx - \mu^2,$$

respectively. Sometimes one way is easier than the other.

In general, if m is a positive integer and if $M^{(m)}(t)$ means the m th derivative of $M(t)$, we have, by repeated differentiation with respect to t ,

$$M^{(m)}(0) = E(X^m).$$

Now

$$E(X^m) = \int_{-\infty}^{\infty} x^m f(x) dx \quad \text{or} \quad \sum_x x^m p(x),$$

and the integrals (or sums) of this sort are, in mechanics, called *moments*. Since $M(t)$ generates the values of $E(X^m)$, $m = 1, 2, 3, \dots$, it is called the moment-generating function (mgf). In fact, we sometimes call $E(X^m)$ the **m th moment** of the distribution, or the m th moment of X .

The next two examples concern random variables whose distributions do not have mgfs.

Example 1.9.5. It is known that the series

$$\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \dots$$

converges to $\pi^2/6$. Then

$$p(x) = \begin{cases} \frac{6}{\pi^2 x^2} & x = 1, 2, 3, \dots \\ 0 & \text{elsewhere} \end{cases}$$

is the pmf of a discrete type of random variable X . The mgf of this distribution, if it exists, is given by

$$\begin{aligned} M(t) &= E(e^{tX}) = \sum_x e^{tx} p(x) \\ &= \sum_{x=1}^{\infty} \frac{6e^{tx}}{\pi^2 x^2}. \end{aligned}$$

The ratio test of calculus⁷ may be used to show that this series diverges if $t > 0$. Thus there does not exist a positive number h such that $M(t)$ exists for $-h < t < h$. Accordingly, the distribution has the pmf $p(x)$ of this example and does not have an mgf. ■

Example 1.9.6. Let X be a continuous random variable with pdf

$$f(x) = \frac{1}{\pi} \frac{1}{x^2 + 1}, \quad -\infty < x < \infty. \quad (1.9.2)$$

This is of course the Cauchy pdf which was introduced in Exercise 1.7.24. Let $t > 0$ be given. If $x > 0$, then by the mean value theorem, for some $0 < \xi_0 < tx$,

$$\frac{e^{tx} - 1}{tx} = e^{\xi_0} \geq 1.$$

Hence, $e^{tx} \geq 1 + tx \geq tx$. This leads to the second inequality in the following derivation:

$$\begin{aligned} \int_{-\infty}^{\infty} e^{tx} \frac{1}{\pi} \frac{1}{x^2 + 1} dx &\geq \int_0^{\infty} e^{tx} \frac{1}{\pi} \frac{1}{x^2 + 1} dx \\ &\geq \int_0^{\infty} \frac{1}{\pi} \frac{tx}{x^2 + 1} dx = \infty. \end{aligned}$$

Because t was arbitrary, the integral does not exist in an open interval of 0. Hence, the mgf of the Cauchy distribution does not exist. ■

Example 1.9.7. Let X have the mgf $M(t) = e^{t^2/2}$, $-\infty < t < \infty$. As discussed in Chapter 3, this is the mgf of a standard normal distribution. We can differentiate $M(t)$ any number of times to find the moments of X . However, it is instructive to

⁷For example, see Chapter 2 of *Mathematical Comments*.

consider this alternative method. The function $M(t)$ is represented by the following Maclaurin's series:⁸

$$\begin{aligned} e^{t^2/2} &= 1 + \frac{1}{1!} \left(\frac{t^2}{2} \right) + \frac{1}{2!} \left(\frac{t^2}{2} \right)^2 + \cdots + \frac{1}{k!} \left(\frac{t^2}{2} \right)^k + \cdots \\ &= 1 + \frac{1}{2!} t^2 + \frac{(3)(1)}{4!} t^4 + \cdots + \frac{(2k-1)\cdots(3)(1)}{(2k)!} t^{2k} + \cdots. \end{aligned}$$

In general, though, from calculus the Maclaurin's series for $M(t)$ is

$$\begin{aligned} M(t) &= M(0) + \frac{M'(0)}{1!} t + \frac{M''(0)}{2!} t^2 + \cdots + \frac{M^{(m)}(0)}{m!} t^m + \cdots \\ &= 1 + \frac{E(X)}{1!} t + \frac{E(X^2)}{2!} t^2 + \cdots + \frac{E(X^m)}{m!} t^m + \cdots. \end{aligned}$$

Thus the coefficient of $(t^m/m!)$ in the Maclaurin's series representation of $M(t)$ is $E(X^m)$. So, for our particular $M(t)$, we have

$$E(X^{2k}) = (2k-1)(2k-3)\cdots(3)(1) = \frac{(2k)!}{2^k k!}, \quad k = 1, 2, 3, \dots \quad (1.9.3)$$

$$E(X^{2k-1}) = 0, \quad k = 1, 2, 3, \dots \quad (1.9.4)$$

We make use of this result in Section 3.4. ■

Remark 1.9.1. As Examples 1.9.5 and 1.9.6 show, distributions may not have moment-generating functions. In a more advanced course, we would let i denote the imaginary unit, t an arbitrary real, and we would define $\varphi(t) = E(e^{itX})$. This expectation exists for *every* distribution and it is called the **characteristic function** of the distribution. To see why $\varphi(t)$ exists for all real t , we note, in the continuous case, that its absolute value

$$|\varphi(t)| = \left| \int_{-\infty}^{\infty} e^{itx} f(x) dx \right| \leq \int_{-\infty}^{\infty} |e^{itx} f(x)| dx.$$

However, $|f(x)| = f(x)$ since $f(x)$ is nonnegative and

$$|e^{itx}| = |\cos tx + i \sin tx| = \sqrt{\cos^2 tx + \sin^2 tx} = 1.$$

Thus

$$|\varphi(t)| \leq \int_{-\infty}^{\infty} f(x) dx = 1.$$

Accordingly, the integral for $\varphi(t)$ exists for all real values of t . In the discrete case, a summation would replace the integral. In reference to Example 1.9.6, it can be shown that the characteristic function of the Cauchy distribution is given by $\varphi(t) = \exp\{-|t|\}$, $-\infty < t < \infty$.

⁸See Chapter 2 of *Mathematical Comments*.

Every distribution has a unique characteristic function; and to each characteristic function there corresponds a unique distribution of probability. If X has a distribution with characteristic function $\varphi(t)$, then, for instance, if $E(X)$ and $E(X^2)$ exist, they are given, respectively, by $iE(X) = \varphi'(0)$ and $i^2 E(X^2) = \varphi''(0)$. Readers who are familiar with complex-valued functions may write $\varphi(t) = M(it)$ and, throughout this book, may prove certain theorems in complete generality.

Those who have studied Laplace and Fourier transforms note a similarity between these transforms and $M(t)$ and $\varphi(t)$; it is the uniqueness of these transforms that allows us to assert the uniqueness of each of the moment-generating and characteristic functions. ■

EXERCISES

1.9.1. Find the mean and variance, if they exist, of each of the following distributions.

(a) $p(x) = \frac{3!}{x!(3-x)!} \left(\frac{1}{2}\right)^3$, $x = 0, 1, 2, 3$, zero elsewhere.

(b) $f(x) = 6x(1-x)$, $0 < x < 1$, zero elsewhere.

(c) $f(x) = 2/x^3$, $1 < x < \infty$, zero elsewhere.

1.9.2. Let $p(x) = (\frac{1}{2})^x$, $x = 1, 2, 3, \dots$, zero elsewhere, be the pmf of the random variable X . Find the mgf, the mean, and the variance of X .

1.9.3. For each of the following distributions, compute $P(\mu - 2\sigma < X < \mu + 2\sigma)$.

(a) $f(x) = 6x(1-x)$, $0 < x < 1$, zero elsewhere.

(b) $p(x) = (\frac{1}{2})^x$, $x = 1, 2, 3, \dots$, zero elsewhere.

1.9.4. If the variance of the random variable X exists, show that

$$E(X^2) \geq [E(X)]^2.$$

1.9.5. Let a random variable X of the continuous type have a pdf $f(x)$ whose graph is symmetric with respect to $x = c$. If the mean value of X exists, show that $E(X) = c$.

Hint: Show that $E(X - c)$ equals zero by writing $E(X - c)$ as the sum of two integrals: one from $-\infty$ to c and the other from c to ∞ . In the first, let $y = c - x$; and, in the second, $z = x - c$. Finally, use the symmetry condition $f(c-y) = f(c+y)$ in the first.

1.9.6. Let the random variable X have mean μ , standard deviation σ , and mgf $M(t)$, $-h < t < h$. Show that

$$E\left(\frac{X - \mu}{\sigma}\right) = 0, \quad E\left[\left(\frac{X - \mu}{\sigma}\right)^2\right] = 1,$$

and

$$E\left\{\exp\left[t\left(\frac{X - \mu}{\sigma}\right)\right]\right\} = e^{-\mu t/\sigma} M\left(\frac{t}{\sigma}\right), \quad -h\sigma < t < h\sigma.$$

1.9.7. Show that the moment generating function of the random variable X having the pdf $f(x) = \frac{1}{3}$, $-1 < x < 2$, zero elsewhere, is

$$M(t) = \begin{cases} \frac{e^{2t}-e^{-t}}{3t} & t \neq 0 \\ 1 & t = 0. \end{cases}$$

1.9.8. Let X be a random variable such that $E[(X - b)^2]$ exists for all real b . Show that $E[(X - b)^2]$ is a minimum when $b = E(X)$.

1.9.9. Let X be a random variable of the continuous type that has pdf $f(x)$. If m is the unique median of the distribution of X and b is a real constant, show that

$$E(|X - b|) = E(|X - m|) + 2 \int_m^b (b - x)f(x) dx,$$

provided that the expectations exist. For what value of b is $E(|X - b|)$ a minimum?

1.9.10. Let X denote a random variable for which $E[(X - a)^2]$ exists. Give an example of a distribution of a discrete type such that this expectation is zero. Such a distribution is called a **degenerate distribution**.

1.9.11. Let X denote a random variable such that $K(t) = E(t^X)$ exists for all real values of t in a certain open interval that includes the point $t = 1$. Show that $K^{(m)}(1)$ is equal to the m th **factorial moment** $E[X(X - 1) \cdots (X - m + 1)]$.

1.9.12. Let X be a random variable. If m is a positive integer, the expectation $E[(X - b)^m]$, if it exists, is called the m th moment of the distribution about the point b . Let the first, second, and third moments of the distribution about the point 7 be 3, 11, and 15, respectively. Determine the mean μ of X , and then find the first, second, and third moments of the distribution about the point μ .

1.9.13. Let X be a random variable such that $R(t) = E(e^{t(X-b)})$ exists for t such that $-h < t < h$. If m is a positive integer, show that $R^{(m)}(0)$ is equal to the m th moment of the distribution about the point b .

1.9.14. Let X be a random variable with mean μ and variance σ^2 such that the third moment $E[(X - \mu)^3]$ about the vertical line through μ exists. The value of the ratio $E[(X - \mu)^3]/\sigma^3$ is often used as a measure of **skewness**. Graph each of the following probability density functions and show that this measure is negative, zero, and positive for these respective distributions (which are said to be skewed to the left, not skewed, and skewed to the right, respectively).

(a) $f(x) = (x + 1)/2$, $-1 < x < 1$, zero elsewhere.

(b) $f(x) = \frac{1}{2}$, $-1 < x < 1$, zero elsewhere.

(c) $f(x) = (1 - x)/2$, $-1 < x < 1$, zero elsewhere.

1.9.15. Let X be a random variable with mean μ and variance σ^2 such that the fourth moment $E[(X - \mu)^4]$ exists. The value of the ratio $E[(X - \mu)^4]/\sigma^4$ is often used as a measure of **kurtosis**. Graph each of the following probability density functions and show that this measure is smaller for the first distribution.

- (a) $f(x) = \frac{1}{2}$, $-1 < x < 1$, zero elsewhere.
 (b) $f(x) = 3(1 - x^2)/4$, $-1 < x < 1$, zero elsewhere.

1.9.16. Let the random variable X have pmf

$$p(x) = \begin{cases} p & x = -1, 1 \\ 1 - 2p & x = 0 \\ 0 & \text{elsewhere,} \end{cases}$$

where $0 < p < \frac{1}{2}$. Find the measure of kurtosis as a function of p . Determine its value when $p = \frac{1}{3}$, $p = \frac{1}{5}$, $p = \frac{1}{10}$, and $p = \frac{1}{100}$. Note that the kurtosis increases as p decreases.

1.9.17. Let $\psi(t) = \log M(t)$, where $M(t)$ is the mgf of a distribution. Prove that $\psi'(0) = \mu$ and $\psi''(0) = \sigma^2$. The function $\psi(t)$ is called the **cumulant generating function**.

1.9.18. Find the mean and the variance of the distribution that has the cdf

$$F(x) = \begin{cases} 0 & x < 0 \\ \frac{x}{8} & 0 \leq x < 2 \\ \frac{x^2}{16} & 2 \leq x < 4 \\ 1 & 4 \leq x. \end{cases}$$

1.9.19. Find the moments of the distribution that has mgf $M(t) = (1-t)^{-3}$, $t < 1$.
Hint: Find the Maclaurin series for $M(t)$.

1.9.20. We say that X has a **Laplace** distribution if its pdf is

$$f(t) = \frac{1}{2}e^{-|t|}, \quad -\infty < t < \infty. \quad (1.9.5)$$

- (a) Show that the mgf of X is $M(t) = (1-t^2)^{-1}$ for $|t| < 1$.
 (b) Expand $M(t)$ into a Maclaurin series and use it to find all the moments of X .

1.9.21. Let X be a random variable of the continuous type with pdf $f(x)$, which is positive provided $0 < x < b < \infty$, and is equal to zero elsewhere. Show that

$$E(X) = \int_0^b [1 - F(x)] dx,$$

where $F(x)$ is the cdf of X .

1.9.22. Let X be a random variable of the discrete type with pmf $p(x)$ that is positive on the nonnegative integers and is equal to zero elsewhere. Show that

$$E(X) = \sum_{x=0}^{\infty} [1 - F(x)],$$

where $F(x)$ is the cdf of X .

1.9.23. Let X have the pmf $p(x) = 1/k$, $x = 1, 2, 3, \dots, k$, zero elsewhere. Show that the mgf is

$$M(t) = \begin{cases} \frac{e^t(1-e^{kt})}{k(1-e^t)} & t \neq 0 \\ 1 & t = 0. \end{cases}$$

1.9.24. Let X have the cdf $F(x)$ that is a mixture of the continuous and discrete types, namely

$$F(x) = \begin{cases} 0 & x < 0 \\ \frac{x+1}{4} & 0 \leq x < 1 \\ 1 & 1 \leq x. \end{cases}$$

Determine reasonable definitions of $\mu = E(X)$ and $\sigma^2 = \text{var}(X)$ and compute each.

Hint: Determine the parts of the pmf and the pdf associated with each of the discrete and continuous parts, and then sum for the discrete part and integrate for the continuous part.

1.9.25. Consider k continuous-type distributions with the following characteristics: pdf $f_i(x)$, mean μ_i , and variance σ_i^2 , $i = 1, 2, \dots, k$. If $c_i \geq 0$, $i = 1, 2, \dots, k$, and $c_1 + c_2 + \dots + c_k = 1$, show that the mean and the variance of the distribution having pdf $c_1 f_1(x) + \dots + c_k f_k(x)$ are $\mu = \sum_{i=1}^k c_i \mu_i$ and $\sigma^2 = \sum_{i=1}^k c_i [\sigma_i^2 + (\mu_i - \mu)^2]$, respectively.

1.9.26. Let X be a random variable with a pdf $f(x)$ and mgf $M(t)$. Suppose f is symmetric about 0; i.e., $f(-x) = f(x)$. Show that $M(-t) = M(t)$.

1.9.27. Let X have the exponential pdf, $f(x) = \beta^{-1} \exp\{-x/\beta\}$, $0 < x < \infty$, zero elsewhere. Find the mgf, the mean, and the variance of X .

1.10 Important Inequalities

In this section, we discuss some famous inequalities involving expectations. We make use of these inequalities in the remainder of the text. We begin with a useful result.

Theorem 1.10.1. *Let X be a random variable and let m be a positive integer. Suppose $E[X^m]$ exists. If k is a positive integer and $k \leq m$, then $E[X^k]$ exists.*

Proof: We prove it for the continuous case; but the proof is similar for the discrete case if we replace integrals by sums. Let $f(x)$ be the pdf of X . Then

$$\begin{aligned} \int_{-\infty}^{\infty} |x|^k f(x) dx &= \int_{|x| \leq 1} |x|^k f(x) dx + \int_{|x| > 1} |x|^k f(x) dx \\ &\leq \int_{|x| \leq 1} f(x) dx + \int_{|x| > 1} |x|^m f(x) dx \\ &\leq \int_{-\infty}^{\infty} f(x) dx + \int_{-\infty}^{\infty} |x|^m f(x) dx \\ &\leq 1 + E[|X|^m] < \infty, \end{aligned} \tag{1.10.1}$$

which is the the desired result. ■

Theorem 1.10.2 (Markov's Inequality). *Let $u(X)$ be a nonnegative function of the random variable X . If $E[u(X)]$ exists, then for every positive constant c ,*

$$P[u(X) \geq c] \leq \frac{E[u(X)]}{c}.$$

Proof. The proof is given when the random variable X is of the continuous type; but the proof can be adapted to the discrete case if we replace integrals by sums. Let $A = \{x : u(x) \geq c\}$ and let $f(x)$ denote the pdf of X . Then

$$E[u(X)] = \int_{-\infty}^{\infty} u(x)f(x) dx = \int_A u(x)f(x) dx + \int_{A^c} u(x)f(x) dx.$$

Since each of the integrals in the extreme right-hand member of the preceding equation is nonnegative, the left-hand member is greater than or equal to either of them. In particular,

$$E[u(X)] \geq \int_A u(x)f(x) dx.$$

However, if $x \in A$, then $u(x) \geq c$; accordingly, the right-hand member of the preceding inequality is not increased if we replace $u(x)$ by c . Thus

$$E[u(X)] \geq c \int_A f(x) dx.$$

Since

$$\int_A f(x) dx = P(X \in A) = P[u(X) \geq c],$$

it follows that

$$E[u(X)] \geq c P[u(X) \geq c],$$

which is the desired result. ■

The preceding theorem is a generalization of an inequality that is often called **Chebyshev's Inequality**. This inequality we now establish.

Theorem 1.10.3 (Chebyshev's Inequality). *Let X be a random variable with finite variance σ^2 (by Theorem 1.10.1, this implies that the mean $\mu = E(X)$ exists). Then for every $k > 0$,*

$$P(|X - \mu| \geq k\sigma) \leq \frac{1}{k^2}, \quad (1.10.2)$$

or, equivalently,

$$P(|X - \mu| < k\sigma) \geq 1 - \frac{1}{k^2}.$$

Proof. In Theorem 1.10.2 take $u(X) = (X - \mu)^2$ and $c = k^2\sigma^2$. Then we have

$$P[(X - \mu)^2 \geq k^2\sigma^2] \leq \frac{E[(X - \mu)^2]}{k^2\sigma^2}.$$

Since the numerator of the right-hand member of the preceding inequality is σ^2 , the inequality may be written

$$P(|X - \mu| \geq k\sigma) \leq \frac{1}{k^2},$$

which is the desired result. Naturally, we would take the positive number k to be greater than 1 to have an inequality of interest. ■

Hence, the number $1/k^2$ is an upper bound for the probability $P(|X - \mu| \geq k\sigma)$. In the following example this upper bound and the exact value of the probability are compared in special instances.

Example 1.10.1. Let X have the uniform pdf

$$f(x) = \begin{cases} \frac{1}{2\sqrt{3}} & -\sqrt{3} < x < \sqrt{3} \\ 0 & \text{elsewhere.} \end{cases}$$

Based on Example 1.9.1, for this uniform distribution, we have $\mu = 0$ and $\sigma^2 = 1$. If $k = \frac{3}{2}$, we have the exact probability

$$P(|X - \mu| \geq k\sigma) = P\left(|X| \geq \frac{3}{2}\right) = 1 - \int_{-3/2}^{3/2} \frac{1}{2\sqrt{3}} dx = 1 - \frac{\sqrt{3}}{2}.$$

By Chebyshev's inequality, this probability has the upper bound $1/k^2 = \frac{4}{9}$. Since $1 - \sqrt{3}/2 = 0.134$, approximately, the exact probability in this case is considerably less than the upper bound $\frac{4}{9}$. If we take $k = 2$, we have the exact probability $P(|X - \mu| \geq 2\sigma) = P(|X| \geq 2) = 0$. This again is considerably less than the upper bound $1/k^2 = \frac{1}{4}$ provided by Chebyshev's inequality. ■

In each of the instances in Example 1.10.1, the probability $P(|X - \mu| \geq k\sigma)$ and its upper bound $1/k^2$ differ considerably. This suggests that this inequality might be made sharper. However, if we want an inequality that holds for every $k > 0$ and holds for all random variables having a finite variance, such an improvement is impossible, as is shown by the following example.

Example 1.10.2. Let the random variable X of the discrete type have probabilities $\frac{1}{8}, \frac{6}{8}, \frac{1}{8}$ at the points $x = -1, 0, 1$, respectively. Here $\mu = 0$ and $\sigma^2 = \frac{1}{4}$. If $k = 2$, then $1/k^2 = \frac{1}{4}$ and $P(|X - \mu| \geq k\sigma) = P(|X| \geq 1) = \frac{1}{4}$. That is, the probability $P(|X - \mu| \geq k\sigma)$ here attains the upper bound $1/k^2 = \frac{1}{4}$. Hence the inequality cannot be improved without further assumptions about the distribution of X . ■

A convenient form of Chebyshev's Inequality is found by taking $k\sigma = \epsilon$ for $\epsilon > 0$. Then Equation (1.10.2) becomes

$$P(|X - \mu| \geq \epsilon) \leq \frac{\sigma^2}{\epsilon^2}, \quad \text{for all } \epsilon > 0. \quad (1.10.3)$$

The second inequality of this section involves convex functions.

Definition 1.10.1. A function ϕ defined on an interval (a, b) , $-\infty \leq a < b \leq \infty$, is said to be a **convex** function if for all x, y in (a, b) and for all $0 < \gamma < 1$,

$$\phi[\gamma x + (1 - \gamma)y] \leq \gamma\phi(x) + (1 - \gamma)\phi(y). \quad (1.10.4)$$

We say ϕ is **strictly convex** if the above inequality is strict.

Depending on the existence of first or second derivatives of ϕ , the following theorem can be proved.

Theorem 1.10.4. If ϕ is differentiable on (a, b) , then

- (a) ϕ is convex if and only if $\phi'(x) \leq \phi'(y)$, for all $a < x < y < b$,
- (b) ϕ is strictly convex if and only if $\phi'(x) < \phi'(y)$, for all $a < x < y < b$.

If ϕ is twice differentiable on (a, b) , then

- (a) ϕ is convex if and only if $\phi''(x) \geq 0$, for all $a < x < b$,
- (b) ϕ is strictly convex if $\phi''(x) > 0$, for all $a < x < b$.

Of course, the second part of this theorem follows immediately from the first part. While the first part appeals to one's intuition, the proof of it can be found in most analysis books; see, for instance, Hewitt and Stromberg (1965). A very useful probability inequality follows from convexity.

Theorem 1.10.5 (Jensen's Inequality). If ϕ is convex on an open interval I and X is a random variable whose support is contained in I and has finite expectation, then

$$\phi[E(X)] \leq E[\phi(X)]. \quad (1.10.5)$$

If ϕ is strictly convex, then the inequality is strict unless X is a constant random variable.

Proof: For our proof we assume that ϕ has a second derivative, but in general only convexity is required. Expand $\phi(x)$ into a Taylor series about $\mu = E[X]$ of order 2:

$$\phi(x) = \phi(\mu) + \phi'(\mu)(x - \mu) + \frac{\phi''(\zeta)(x - \mu)^2}{2},$$

where ζ is between x and μ .⁹ Because the last term on the right side of the above equation is nonnegative, we have

$$\phi(x) \geq \phi(\mu) + \phi'(\mu)(x - \mu).$$

Taking expectations of both sides leads to the result. The inequality is strict if $\phi''(x) > 0$, for all $x \in (a, b)$, provided X is not a constant. ■

⁹See, for example, the discussion on Taylor series in *Mathematical Comments* referenced in the Preface.

Example 1.10.3. Let X be a nondegenerate random variable with mean μ and a finite second moment. Then $\mu^2 < E(X^2)$. This is obtained by Jensen's inequality using the strictly convex function $\phi(t) = t^2$. ■

The last inequality concerns different means of finite sets of positive numbers.

Example 1.10.4 (Harmonic and Geometric Means). Let $\{a_1, \dots, a_n\}$ be a set of positive numbers. Create a distribution for a random variable X by placing weight $1/n$ on each of the numbers a_1, \dots, a_n . Then the mean of X is the **arithmetic mean**, (AM), $E(X) = n^{-1} \sum_{i=1}^n a_i$. Then, since $-\log x$ is a convex function, we have by Jensen's inequality that

$$-\log \left(\frac{1}{n} \sum_{i=1}^n a_i \right) \leq E(-\log X) = -\frac{1}{n} \sum_{i=1}^n \log a_i = -\log(a_1 a_2 \cdots a_n)^{1/n}$$

or, equivalently,

$$\log \left(\frac{1}{n} \sum_{i=1}^n a_i \right) \geq \log(a_1 a_2 \cdots a_n)^{1/n},$$

and, hence,

$$(a_1 a_2 \cdots a_n)^{1/n} \leq \frac{1}{n} \sum_{i=1}^n a_i. \quad (1.10.6)$$

The quantity on the left side of this inequality is called the **geometric mean** (GM). So (1.10.6) is equivalent to saying that $GM \leq AM$ for any finite set of positive numbers.

Now in (1.10.6) replace a_i by $1/a_i$ (which is also positive). We then obtain

$$\frac{1}{n} \sum_{i=1}^n \frac{1}{a_i} \geq \left(\frac{1}{a_1} \frac{1}{a_2} \cdots \frac{1}{a_n} \right)^{1/n}$$

or, equivalently,

$$\frac{1}{\frac{1}{n} \sum_{i=1}^n \frac{1}{a_i}} \leq (a_1 a_2 \cdots a_n)^{1/n}. \quad (1.10.7)$$

The left member of this inequality is called the **harmonic mean** (HM). Putting (1.10.6) and (1.10.7) together, we have shown the relationship

$$HM \leq GM \leq AM, \quad (1.10.8)$$

for any finite set of positive numbers. ■

EXERCISES

1.10.1. Let X be a random variable with mean μ and let $E[(X - \mu)^{2k}]$ exist. Show, with $d > 0$, that $P(|X - \mu| \geq d) \leq E[(X - \mu)^{2k}] / d^{2k}$. This is essentially Chebyshev's inequality when $k = 1$. The fact that this holds for all $k = 1, 2, 3, \dots$, when those $(2k)$ th moments exist, usually provides a much smaller upper bound for $P(|X - \mu| \geq d)$ than does Chebyshev's result.

1.10.2. Let X be a random variable such that $P(X \leq 0) = 0$ and let $\mu = E(X)$ exist. Show that $P(X \geq 2\mu) \leq \frac{1}{2}$.

1.10.3. If X is a random variable such that $E(X) = 3$ and $E(X^2) = 13$, use Chebyshev's inequality to determine a lower bound for the probability $P(-2 < X < 8)$.

1.10.4. Suppose X has a Laplace distribution with pdf (1.9.20). Show that the mean and variance of X are 0 and 2, respectively. Using Chebyshev's inequality determine the upper bound for $P(|X| \geq 5)$ and then compare it with the exact probability.

1.10.5. Let X be a random variable with mgf $M(t)$, $-h < t < h$. Prove that

$$P(X \geq a) \leq e^{-at} M(t), \quad 0 < t < h,$$

and that

$$P(X \leq a) \leq e^{-at} M(t), \quad -h < t < 0.$$

Hint: Let $u(x) = e^{tx}$ and $c = e^{ta}$ in Theorem 1.10.2. *Note:* These results imply that $P(X \geq a)$ and $P(X \leq a)$ are less than or equal to their respective least upper bounds for $e^{-at} M(t)$ when $0 < t < h$ and when $-h < t < 0$.

1.10.6. The mgf of X exists for all real values of t and is given by

$$M(t) = \frac{e^t - e^{-t}}{2t}, \quad t \neq 0, \quad M(0) = 1.$$

Use the results of the preceding exercise to show that $P(X \geq 1) = 0$ and $P(X \leq -1) = 0$. Note that here h is infinite.

1.10.7. Let X be a positive random variable; i.e., $P(X \leq 0) = 0$. Argue that

- (a) $E(1/X) \geq 1/E(X)$
- (b) $E[-\log X] \geq -\log[E(X)]$
- (c) $E[\log(1/X)] \geq \log[1/E(X)]$
- (d) $E[X^3] \geq [E(X)]^3$.

Chapter 2

Multivariate Distributions

2.1 Distributions of Two Random Variables

We begin the discussion of a pair of random variables with the following example. A coin is tossed three times and our interest is in the ordered number pair (number of H's on first two tosses, number of H's on all three tosses), where H and T represent, respectively, heads and tails. Let $\mathcal{C} = \{\text{TTT}, \text{TTH}, \text{THT}, \text{HTT}, \text{THH}, \text{HTH}, \text{HHT}, \text{HHH}\}$ denote the sample space. Let X_1 denote the number of H's on the first two tosses and X_2 denote the number of H's on all three flips. Then our interest can be represented by the pair of random variables (X_1, X_2) . For example, $(X_1(\text{HTH}), X_2(\text{HTH}))$ represents the outcome $(1, 2)$. Continuing in this way, X_1 and X_2 are real-valued functions defined on the sample space \mathcal{C} , which take us from the sample space to the space of ordered number pairs.

$$\mathcal{D} = \{(0, 0), (0, 1), (1, 1), (1, 2), (2, 2), (2, 3)\}.$$

Thus X_1 and X_2 are two random variables defined on the space \mathcal{C} , and, in this example, the space of these random variables is the two-dimensional set \mathcal{D} , which is a subset of two-dimensional Euclidean space R^2 . Hence (X_1, X_2) is a vector function from \mathcal{C} to \mathcal{D} . We now formulate the definition of a random vector.

Definition 2.1.1 (Random Vector). *Given a random experiment with a sample space \mathcal{C} , consider two random variables X_1 and X_2 , which assign to each element c of \mathcal{C} one and only one ordered pair of numbers $X_1(c) = x_1$, $X_2(c) = x_2$. Then we say that (X_1, X_2) is a **random vector**. The **space** of (X_1, X_2) is the set of ordered pairs $\mathcal{D} = \{(x_1, x_2) : x_1 = X_1(c), x_2 = X_2(c), c \in \mathcal{C}\}$.*

We often denote random vectors using vector notation $\mathbf{X} = (X_1, X_2)'$, where the ' denotes the transpose of the row vector (X_1, X_2) . Also, we often use (X, Y) to denote random vectors.

Let \mathcal{D} be the space associated with the random vector (X_1, X_2) . Let A be a subset of \mathcal{D} . As in the case of one random variable, we speak of the event A . We wish to define the probability of the event A , which we denote by $P_{X_1, X_2}[A]$. As

with random variables in Section 1.5 we can uniquely define P_{X_1, X_2} in terms of the **cumulative distribution function** (cdf), which is given by

$$F_{X_1, X_2}(x_1, x_2) = P[\{X_1 \leq x_1\} \cap \{X_2 \leq x_2\}], \quad (2.1.1)$$

for all $(x_1, x_2) \in R^2$. Because X_1 and X_2 are random variables, each of the events in the above intersection and the intersection of the events are events in the original sample space \mathcal{C} . Thus the expression is well defined. As with random variables, we write $P[\{X_1 \leq x_1\} \cap \{X_2 \leq x_2\}]$ as $P[X_1 \leq x_1, X_2 \leq x_2]$. As Exercise 2.1.3 shows,

$$\begin{aligned} P[a_1 < X_1 \leq b_1, a_2 < X_2 \leq b_2] &= F_{X_1, X_2}(b_1, b_2) - F_{X_1, X_2}(a_1, b_2) \\ &\quad - F_{X_1, X_2}(b_1, a_2) + F_{X_1, X_2}(a_1, a_2). \end{aligned} \quad (2.1.2)$$

Hence, all induced probabilities of sets of the form $(a_1, b_1] \times (a_2, b_2]$ can be formulated in terms of the cdf. We often call this cdf the **joint cumulative distribution function** of (X_1, X_2) .

As with random variables, we are mainly concerned with two types of random vectors, namely discrete and continuous. We first discuss the discrete type.

A random vector (X_1, X_2) is a **discrete random vector** if its space \mathcal{D} is finite or countable. Hence, X_1 and X_2 are both discrete also. The **joint probability mass function** (pmf) of (X_1, X_2) is defined by

$$p_{X_1, X_2}(x_1, x_2) = P[X_1 = x_1, X_2 = x_2], \quad (2.1.3)$$

for all $(x_1, x_2) \in \mathcal{D}$. As with random variables, the pmf uniquely defines the cdf. It also is characterized by the two properties

$$(i) \ 0 \leq p_{X_1, X_2}(x_1, x_2) \leq 1 \text{ and } (ii) \sum_{\mathcal{D}} p_{X_1, X_2}(x_1, x_2) = 1. \quad (2.1.4)$$

For an event $B \in \mathcal{D}$, we have

$$P[(X_1, X_2) \in B] = \sum_B \sum p_{X_1, X_2}(x_1, x_2).$$

Example 2.1.1. Consider the example at the beginning of this section where a fair coin is flipped three times and X_1 and X_2 are the number of heads on the first two flips and all 3 flips, respectively. We can conveniently table the pmf of (X_1, X_2) as

		Support of X_2			
		0	1	2	3
Support of X_1	0	$\frac{1}{8}$	$\frac{1}{8}$	0	0
	1	0	$\frac{2}{8}$	$\frac{2}{8}$	0
	2	0	0	$\frac{1}{8}$	$\frac{1}{8}$

For instance, $P(X_1 \geq 2, X_2 \geq 2) = p(2, 2) + p(2, 3) = 2/8$. ■

At times it is convenient to speak of the **support** of a discrete random vector (X_1, X_2) . These are all the points (x_1, x_2) in the space of (X_1, X_2) such that $p(x_1, x_2) > 0$. In the last example the support consists of the six points $\{(0, 0), (0, 1), (1, 1), (1, 2), (2, 2), (2, 3)\}$.

We say a random vector (X_1, X_2) with space \mathcal{D} is of the **continuous** type if its cdf $F_{X_1, X_2}(x_1, x_2)$ is continuous. For the most part, the continuous random vectors in this book have cdfs that can be represented as integrals of nonnegative functions. That is, $F_{X_1, X_2}(x_1, x_2)$ can be expressed as

$$F_{X_1, X_2}(x_1, x_2) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} f_{X_1, X_2}(w_1, w_2) dw_1 dw_2, \quad (2.1.5)$$

for all $(x_1, x_2) \in R^2$. We call the integrand the **joint probability density function** (pdf) of (X_1, X_2) . Then

$$\frac{\partial^2 F_{X_1, X_2}(x_1, x_2)}{\partial x_1 \partial x_2} = f_{X_1, X_2}(x_1, x_2),$$

except possibly on events that have probability zero. A pdf is essentially characterized by the two properties

$$(i) f_{X_1, X_2}(x_1, x_2) \geq 0 \text{ and } (ii) \int \int_{\mathcal{D}} f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 = 1. \quad (2.1.6)$$

For the reader's benefit, Section 4.2 of the accompanying resource *Mathematical Comments*¹ offers a short review of double integration. For an event $A \in \mathcal{D}$, we have

$$P[(X_1, X_2) \in A] = \int \int_A f_{X_1, X_2}(x_1, x_2) dx_1 dx_2.$$

Note that the $P[(X_1, X_2) \in A]$ is just the volume under the surface $z = f_{X_1, X_2}(x_1, x_2)$ over the set A .

Remark 2.1.1. As with univariate random variables, we often drop the subscript (X_1, X_2) from joint cdfs, pdfs, and pmfs, when it is clear from the context. We also use notation such as f_{12} instead of f_{X_1, X_2} . Besides (X_1, X_2) , we often use (X, Y) to express random vectors. ■

We next present two examples of jointly continuous random variables.

Example 2.1.2. Consider a continuous random vector (X, Y) which is uniformly distributed over the unit circle in R^2 . Since the area of the unit circle is π , the joint pdf is

$$f(x, y) = \begin{cases} \frac{1}{\pi} & -1 < y < 1, -\sqrt{1-y^2} < x < \sqrt{1-y^2} \\ 0 & \text{elsewhere.} \end{cases}$$

Probabilities of certain events follow immediately from geometry. For instance, let A be the interior of the circle with radius $1/2$. Then $P[(X, Y) \in A] = \pi(1/2)^2/\pi = 1/4$. Next, let B be the ring formed by the concentric circles with the respective radii of $1/2$ and $\sqrt{2}/2$. Then $P[(X, Y) \in B] = \pi[(\sqrt{2}/2)^2 - (1/2)^2]/\pi = 1/4$. The regions A and B have the same area and hence for this uniform pdf are equilikely. ■

¹Downloadable at the site listed in the Preface.

In the next example, we use the general fact that double integrals can be expressed as iterated univariate integrals. Thus double integrations can be carried out using iterated univariate integrations. This is discussed in some detail with examples in Section 4.2 of the accompanying resource *Mathematical Comments*.² The aid of a simple sketch of the region of integration is valuable in setting up the upper and lower limits of integration for each of the iterated integrals.

Example 2.1.3. Suppose an electrical component has two batteries. Let X and Y denote the lifetimes in standard units of the respective batteries. Assume that the pdf of (X, Y) is

$$f(x, y) = \begin{cases} 4xye^{-(x^2+y^2)} & x > 0, y > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

The surface $z = f(x, y)$ is sketched in Figure 2.1.1 where the grid squares are 0.1 by 0.1. From the figure, the pdf peaks at about $(x, y) = (0.7, 0.7)$. Solving the equations $\partial f / \partial x = 0$ and $\partial f / \partial y = 0$ simultaneously shows that actually the maximum of $f(x, y)$ occurs at $(x, y) = (\sqrt{2}/2, \sqrt{2}/2)$. The batteries are more likely to die in regions near the peak. The surface tapers to 0 as x and y get large in any direction. for instance, the probability that both batteries survive beyond $\sqrt{2}/2$ units is given by

$$\begin{aligned} P\left(X > \frac{\sqrt{2}}{2}, Y > \frac{\sqrt{2}}{2}\right) &= \int_{\sqrt{2}/2}^{\infty} \int_{\sqrt{2}/2}^{\infty} 4xye^{-(x^2+y^2)} dx dy \\ &= \int_{\sqrt{2}/2}^{\infty} 2xe^{-x^2} \left[\int_{\sqrt{2}/2}^{\infty} 2ye^{-y^2} dy \right] dx \\ &= \int_{1/2}^{\infty} e^{-z} \left[\int_{1/2}^{\infty} e^{-w} dw \right] dz = \left(e^{-1/2}\right)^2 \approx 0.3679, \end{aligned}$$

where we made use of the change-in-variables $z = x^2$ and $w = y^2$. In contrast to the last example, consider the regions $A = \{(x, y) : |x - (1/2)| < 0.3, |y - (1/2)| < 0.3\}$ and $B = \{(x, y) : |x - 2| < 0.3, |y - 2| < 0.3\}$. The reader should locate these regions on Figure 2.1.1. The areas of A and B are the same, but it is clear from the figure that $P[(X, Y) \in A]$ is much larger than $P[(X, Y) \in B]$. Exercise 2.1.6 confirms this by showing that $P[(X, Y) \in A] = 0.1879$ while $P[(X, Y) \in B] = 0.0026$. ■

For a continuous random vector (X_1, X_2) , the **support** of (X_1, X_2) contains all points (x_1, x_2) for which $f(x_1, x_2) > 0$. We denote the support of a random vector by \mathcal{S} . As in the univariate case, $\mathcal{S} \subset \mathcal{D}$.

As in the last two examples, we extend the definition of a pdf $f_{X_1, X_2}(x_1, x_2)$ over R^2 by using zero elsewhere. We do this consistently so that tedious, repetitious references to the space \mathcal{D} can be avoided. Once this is done, we replace

$$\int \int_{\mathcal{D}} f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \quad \text{by} \quad \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x_1, x_2) dx_1 dx_2.$$

²Downloadable at the site listed in the Preface.

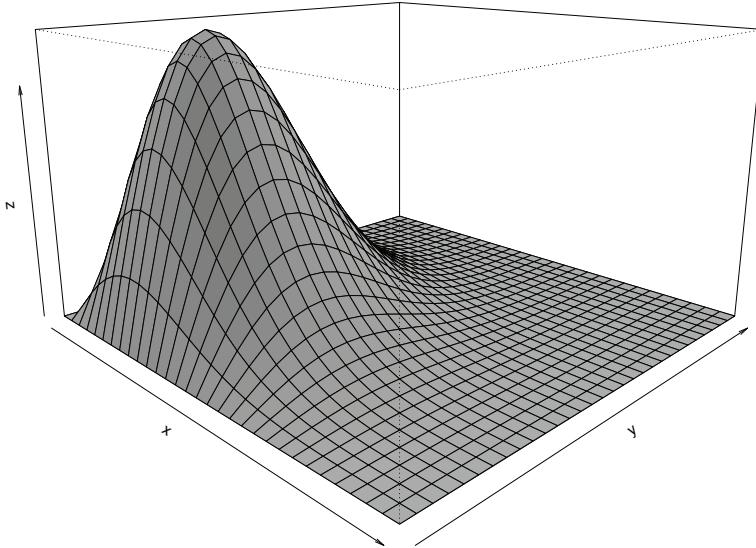

Figure 2.1.1: A sketch of the the surface of the joint pdf discussed in Example 2.1.3. On the figure, the origin is located at the intersection of the x and z axes and the grid squares are 0.1 by 0.1, so points are easily located. As discussed in the text, the peak of the pdf occurs at the point $(\sqrt{2}/2, \sqrt{2}/2)$.

Likewise we may extend the pmf $p_{X_1, X_2}(x_1, x_2)$ over a convenient set by using zero elsewhere. Hence, we replace

$$\sum_{\mathcal{D}} \sum p_{X_1, X_2}(x_1, x_2) \quad \text{by} \quad \sum_{x_2} \sum_{x_1} p(x_1, x_2).$$

2.1.1 Marginal Distributions

Let (X_1, X_2) be a random vector. Then both X_1 and X_2 are random variables. We can obtain their distributions in terms of the joint distribution of (X_1, X_2) as follows. Recall that the event which defined the cdf of X_1 at x_1 is $\{X_1 \leq x_1\}$. However,

$$\{X_1 \leq x_1\} = \{X_1 \leq x_1\} \cap \{-\infty < X_2 < \infty\} = \{X_1 \leq x_1, -\infty < X_2 < \infty\}.$$

Taking probabilities, we have

$$F_{X_1}(x_1) = P[X_1 \leq x_1, -\infty < X_2 < \infty], \quad (2.1.7)$$

Table 2.1.1: Joint and Marginal Distributions for the discrete random vector (X_1, X_2) of Example 2.1.1.

		Support of X_2				$p_{X_1}(x_1)$
		0	1	2	3	
Support of X_1	0	$\frac{1}{8}$	$\frac{1}{8}$	0	0	$\frac{2}{8}$
	1	0	$\frac{2}{8}$	$\frac{2}{8}$	0	$\frac{4}{8}$
	2	0	0	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{2}{8}$
		$p_{X_2}(x_2)$	$\frac{1}{8}$	$\frac{3}{8}$	$\frac{3}{8}$	$\frac{1}{8}$

for all $x_1 \in R$. By Theorem 1.3.6 we can write this equation as $F_{X_1}(x_1) = \lim_{x_2 \uparrow \infty} F(x_1, x_2)$. Thus we have a relationship between the cdfs, which we can extend to either the pmf or pdf depending on whether (X_1, X_2) is discrete or continuous.

First consider the discrete case. Let \mathcal{D}_{X_1} be the support of X_1 . For $x_1 \in \mathcal{D}_{X_1}$, Equation (2.1.7) is equivalent to

$$F_{X_1}(x_1) = \sum_{w_1 \leq x_1, -\infty < x_2 < \infty} p_{X_1, X_2}(w_1, x_2) = \sum_{w_1 \leq x_1} \left\{ \sum_{x_2 < \infty} p_{X_1, X_2}(w_1, x_2) \right\}.$$

By the uniqueness of cdfs, the quantity in braces must be the pmf of X_1 evaluated at w_1 ; that is,

$$p_{X_1}(x_1) = \sum_{x_2 < \infty} p_{X_1, X_2}(x_1, x_2), \quad (2.1.8)$$

for all $x_1 \in \mathcal{D}_{X_1}$. Hence, to find the probability that X_1 is x_1 , keep x_1 fixed and sum p_{X_1, X_2} over all of x_2 . In terms of a tabled joint pmf with rows comprised of X_1 support values and columns comprised of X_2 support values, this says that the distribution of X_1 can be obtained by the marginal sums of the rows. Likewise, the pmf of X_2 can be obtained by marginal sums of the columns.

Consider the joint discrete distribution of the random vector (X_1, X_2) as presented in Example 2.1.1. In Table 2.1.1, we have added these marginal sums. The final row of this table is the pmf of X_2 , while the final column is the pmf of X_1 . In general, because these distributions are recorded in the margins of the table, we often refer to them as **marginal** pmfs.

Example 2.1.4. Consider a random experiment that consists of drawing at random one chip from a bowl containing 10 chips of the same shape and size. Each chip has an ordered pair of numbers on it: one with $(1, 1)$, one with $(2, 1)$, two with $(3, 1)$, one with $(1, 2)$, two with $(2, 2)$, and three with $(3, 2)$. Let the random variables X_1 and X_2 be defined as the respective first and second values of the ordered pair. Thus the joint pmf $p(x_1, x_2)$ of X_1 and X_2 can be given by the following table, with $p(x_1, x_2)$ equal to zero elsewhere.

	x_2		
x_1	1	2	$p_1(x_1)$
1	$\frac{1}{10}$	$\frac{1}{10}$	$\frac{2}{10}$
2	$\frac{1}{10}$	$\frac{2}{10}$	$\frac{3}{10}$
3	$\frac{2}{10}$	$\frac{3}{10}$	$\frac{5}{10}$
$p_2(x_2)$	$\frac{4}{10}$	$\frac{6}{10}$	

The joint probabilities have been summed in each row and each column and these sums recorded in the margins to give the marginal probability mass functions of X_1 and X_2 , respectively. Note that it is not necessary to have a formula for $p(x_1, x_2)$ to do this. ■

We next consider the continuous case. Let \mathcal{D}_{X_1} be the support of X_1 . For $x_1 \in \mathcal{D}_{X_1}$, Equation (2.1.7) is equivalent to

$$F_{X_1}(x_1) = \int_{-\infty}^{x_1} \int_{-\infty}^{\infty} f_{X_1, X_2}(w_1, x_2) dx_2 dw_1 = \int_{-\infty}^{x_1} \left\{ \int_{-\infty}^{\infty} f_{X_1, X_2}(w_1, x_2) dx_2 \right\} dw_1.$$

By the uniqueness of cdfs, the quantity in braces must be the pdf of X_1 , evaluated at w_1 ; that is,

$$f_{X_1}(x_1) = \int_{-\infty}^{\infty} f_{X_1, X_2}(x_1, x_2) dx_2 \quad (2.1.9)$$

for all $x_1 \in \mathcal{D}_{X_1}$. Hence, in the continuous case the marginal pdf of X_1 is found by integrating out x_2 . Similarly, the marginal pdf of X_2 is found by integrating out x_1 .

Example 2.1.5 (Example 2.1.2, continued). Consider the vector of continuous random variables (X, Y) discussed in Example 2.1.2. The space of the random vector is the unit circle with center at $(0, 0)$ as shown in Figure 2.1.2. To find the marginal distribution of X , fix x between -1 and 1 and then integrate out y from $-\sqrt{1-x^2}$ to $\sqrt{1-x^2}$ as the arrow shows on Figure 2.1.2. Hence, the marginal pdf of X is

$$f_X(x) = \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \frac{1}{\pi} dy = \frac{2}{\pi} \sqrt{1-x^2}, \quad -1 < x < 1.$$

Although (X, Y) has a joint uniform distribution, the distribution of X is unimodal with peak at 0. This is not surprising. Since the joint distribution is uniform, from Figure 2.1.2 X is more likely to be near 0 than at either extreme -1 or 1 . Because the joint pdf is symmetric in x and y , the marginal pdf of Y is the same as that of X . ■

Example 2.1.6. Let X_1 and X_2 have the joint pdf

$$f(x_1, x_2) = \begin{cases} x_1 + x_2 & 0 < x_1 < 1, \quad 0 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

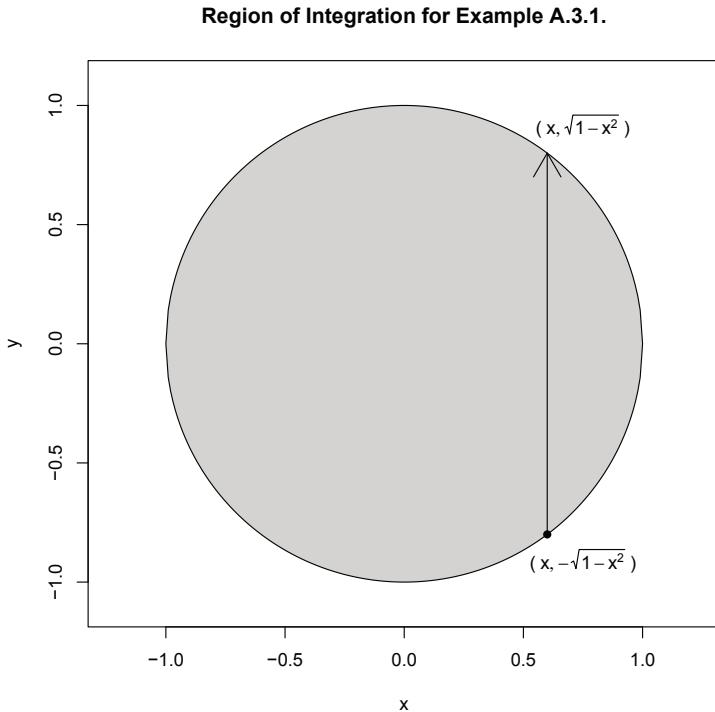

Figure 2.1.2: Region of integration for Example 2.1.5. It depicts the integration with respect to y at a fixed but arbitrary x .

Notice the space of the random vector is the interior of the square with vertices $(0,0)$, $(1,0)$, $(1,1)$ and $(0,1)$. The marginal pdf of X_1 is

$$f_1(x_1) = \int_0^1 (x_1 + x_2) dx_2 = x_1 + \frac{1}{2}, \quad 0 < x_1 < 1,$$

zero elsewhere, and the marginal pdf of X_2 is

$$f_2(x_2) = \int_0^1 (x_1 + x_2) dx_1 = \frac{1}{2} + x_2, \quad 0 < x_2 < 1,$$

zero elsewhere. A probability like $P(X_1 \leq \frac{1}{2})$ can be computed from either $f_1(x_1)$ or $f(x_1, x_2)$ because

$$\int_0^{1/2} \int_0^1 f(x_1, x_2) dx_2 dx_1 = \int_0^{1/2} f_1(x_1) dx_1 = \frac{3}{8}.$$

Suppose, though, we want to find the probability $P(X_1 + X_2 \leq 1)$. Notice that the region of integration is the interior of the triangle with vertices $(0,0)$, $(1,0)$ and

$(0, 1)$. The reader should sketch this region on the space of (X_1, X_2) . Fixing x_1 and integrating with respect to x_2 , we have

$$\begin{aligned} P(X_1 + X_2 \leq 1) &= \int_0^1 \left[\int_0^{1-x_1} (x_1 + x_2) dx_2 \right] dx_1 \\ &= \int_0^1 \left[x_1(1-x_1) + \frac{(1-x_1)^2}{2} \right] dx_1 \\ &= \int_0^1 \left(\frac{1}{2} - \frac{1}{2}x_1^2 \right) dx_1 = \frac{1}{3}. \end{aligned}$$

This latter probability is the volume under the surface $f(x_1, x_2) = x_1 + x_2$ above the set $\{(x_1, x_2) : 0 < x_1, x_1 + x_2 \leq 1\}$. ■

Example 2.1.7 (Example 2.1.3, Continued). Recall that the random variables X and Y of Example 2.1.3 were the lifetimes of two batteries installed in an electrical component. The joint pdf of (X, Y) is sketched in Figure 2.1.1. Its space is the positive quadrant of R^2 so there are no constraints involving both x and y . Using the change-in-variable $w = y^2$, the marginal pdf of X is

$$f_X(x) = \int_0^\infty 4xye^{-(x^2+y^2)} dy = 2xe^{-x^2} \int_0^\infty e^{-w} dw = 2xe^{-x^2},$$

for $x > 0$. By the symmetry of x and y in the model, the pdf of Y is the same as that of X . To determine the median lifetime, θ , of these batteries, we need to solve

$$\frac{1}{2} = \int_0^\theta 2xe^{-x^2} dx = 1 - e^{-\theta^2},$$

where again we have made use of the change-in-variables $z = x^2$. Solving this equation, we obtain $\theta = \sqrt{\log 2} \approx 0.8326$. So 50% of the batteries have lifetimes exceeding 0.83 units. ■

2.1.2 Expectation

The concept of expectation extends in a straightforward manner. Let (X_1, X_2) be a random vector and let $Y = g(X_1, X_2)$ for some real-valued function; i.e., $g : R^2 \rightarrow R$. Then Y is a random variable and we could determine its expectation by obtaining the distribution of Y . But Theorem 1.8.1 is true for random vectors also. Note the proof we gave for this theorem involved the discrete case, and Exercise 2.1.12 shows its extension to the random vector case.

Suppose (X_1, X_2) is of the continuous type. Then $E(Y)$ exists if

$$\int_{-\infty}^\infty \int_{-\infty}^\infty |g(x_1, x_2)| f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 < \infty.$$

Then

$$E(Y) = \int_{-\infty}^\infty \int_{-\infty}^\infty g(x_1, x_2) f_{X_1, X_2}(x_1, x_2) dx_1 dx_2. \quad (2.1.10)$$

Likewise if (X_1, X_2) is discrete, then $E(Y)$ exists if

$$\sum_{x_1} \sum_{x_2} |g(x_1, x_2)| p_{X_1, X_2}(x_1, x_2) < \infty.$$

Then

$$E(Y) = \sum_{x_1} \sum_{x_2} g(x_1, x_2) p_{X_1, X_2}(x_1, x_2). \quad (2.1.11)$$

We can now show that E is a linear operator.

Theorem 2.1.1. Let (X_1, X_2) be a random vector. Let $Y_1 = g_1(X_1, X_2)$ and $Y_2 = g_2(X_1, X_2)$ be random variables whose expectations exist. Then for all real numbers k_1 and k_2 ,

$$E(k_1 Y_1 + k_2 Y_2) = k_1 E(Y_1) + k_2 E(Y_2). \quad (2.1.12)$$

Proof: We prove it for the continuous case. The existence of the expected value of $k_1 Y_1 + k_2 Y_2$ follows directly from the triangle inequality and linearity of integrals; i.e.,

$$\begin{aligned} & \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} |k_1 g_1(x_1, x_2) + k_2 g_2(x_1, x_2)| f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ & \leq |k_1| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} |g_1(x_1, x_2)| f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ & \quad + |k_2| \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} |g_2(x_1, x_2)| f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 < \infty. \end{aligned}$$

By once again using linearity of the integral, we have

$$\begin{aligned} E(k_1 Y_1 + k_2 Y_2) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [k_1 g_1(x_1, x_2) + k_2 g_2(x_1, x_2)] f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ &= k_1 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g_1(x_1, x_2) f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ & \quad + k_2 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g_2(x_1, x_2) f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ &= k_1 E(Y_1) + k_2 E(Y_2), \end{aligned}$$

i.e., the desired result. ■

We also note that the expected value of any function $g(X_2)$ of X_2 can be found in two ways:

$$E(g(X_2)) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x_2) f(x_1, x_2) dx_1 dx_2 = \int_{-\infty}^{\infty} g(x_2) f_{X_2}(x_2) dx_2,$$

the latter single integral being obtained from the double integral by integrating on x_1 first. The following example illustrates these ideas.

Example 2.1.8. Let X_1 and X_2 have the pdf

$$f(x_1, x_2) = \begin{cases} 8x_1x_2 & 0 < x_1 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Figure 2.1.3 shows the space for (X_1, X_2) . Then

$$E(X_1 X_2^2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x_1 x_2^2 f(x_1, x_2) dx_1 dx_2.$$

To compute the integration, as shown by the arrow on Figure 2.1.3, we fix x_2 and then integrate x_1 from 0 to x_2 . We then integrate out x_2 from 0 to 1. Hence,

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x_1 x_2^2 f(x_1, x_2) dx_1 dx_2 = \int_0^1 \left[\int_0^{x_2} 8x_1^2 x_2^3 dx_1 \right] dx_2 = \int_0^1 \frac{8}{3} x_2^6 dx_2 = \frac{8}{21}.$$

In addition,

$$E(X_2) = \int_0^1 \left[\int_0^{x_2} x_2 (8x_1 x_2) dx_1 \right] dx_2 = \frac{4}{5}.$$

Since X_2 has the pdf $f_2(x_2) = 4x_2^3$, $0 < x_2 < 1$, zero elsewhere, the latter expectation can also be found by

$$E(X_2) = \int_0^1 x_2 (4x_2^3) dx_2 = \frac{4}{5}.$$

Using Theorem 2.1.1,

$$\begin{aligned} E(7X_1 X_2^2 + 5X_2) &= 7E(X_1 X_2^2) + 5E(X_2) \\ &= (7)(\frac{8}{21}) + (5)(\frac{4}{5}) = \frac{20}{3}. \quad \blacksquare \end{aligned}$$

Example 2.1.9. Continuing with Example 2.1.8, suppose the random variable Y is defined by $Y = X_1/X_2$. We determine $E(Y)$ in two ways. The first way is by definition; i.e., find the distribution of Y and then determine its expectation. The cdf of Y , for $0 < y \leq 1$, is

$$\begin{aligned} F_Y(y) &= P(Y \leq y) = P(X_1 \leq yX_2) = \int_0^1 \left[\int_0^{yx_2} 8x_1 x_2 dx_1 \right] dx_2 \\ &= \int_0^1 4y^2 x_2^3 dx_2 = y^2. \end{aligned}$$

Hence, the pdf of Y is

$$f_Y(y) = F'_Y(y) = \begin{cases} 2y & 0 < y < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

which leads to

$$E(Y) = \int_0^1 y(2y) dy = \frac{2}{3}.$$

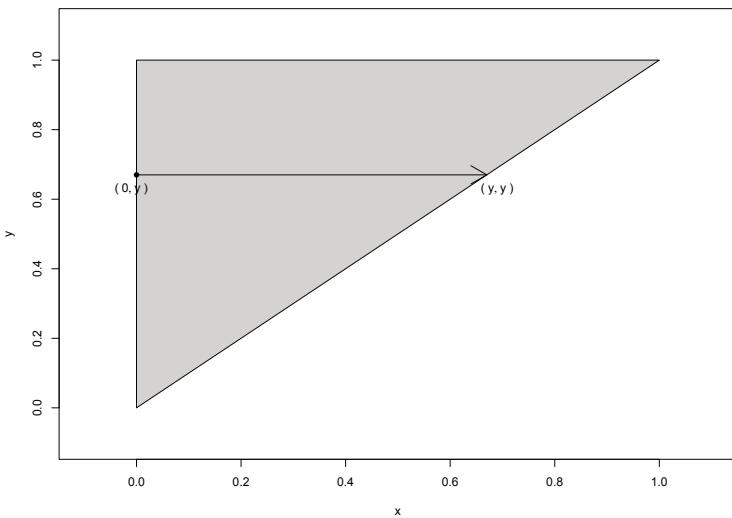

Figure 2.1.3: Region of integration for Example 2.1.8. The arrow depicts the integration with respect to x_1 at a fixed but arbitrary x_2 .

For the second way, we make use of expression (2.1.10) and find $E(Y)$ directly by

$$\begin{aligned} E(Y) &= E\left(\frac{X_1}{X_2}\right) = \int_0^1 \left\{ \int_0^{x_2} \left(\frac{x_1}{x_2} \right) 8x_1 x_2 dx_1 \right\} dx_2 \\ &= \int_0^1 \frac{8}{3} x_2^3 dx_2 = \frac{2}{3}. \blacksquare \end{aligned}$$

We next define the moment generating function of a random vector.

Definition 2.1.2 (Moment Generating Function of a Random Vector). *Let $\mathbf{X} = (X_1, X_2)'$ be a random vector. If $E(e^{t_1 X_1 + t_2 X_2})$ exists for $|t_1| < h_1$ and $|t_2| < h_2$, where h_1 and h_2 are positive, it is denoted by $M_{X_1, X_2}(t_1, t_2)$ and is called the moment generating function (mgf) of \mathbf{X} .*

As in the one-variable case, if it exists, the mgf of a random vector uniquely determines the distribution of the random vector.

Let $\mathbf{t} = (t_1, t_2)'$. Then we can write the mgf of \mathbf{X} as

$$M_{X_1, X_2}(\mathbf{t}) = E[e^{\mathbf{t}' \mathbf{X}}], \quad (2.1.13)$$

so it is quite similar to the mgf of a random variable. Also, the mgfs of X_1 and X_2 are immediately seen to be $M_{X_1, X_2}(t_1, 0)$ and $M_{X_1, X_2}(0, t_2)$, respectively. If there is no confusion, we often drop the subscripts on M .

Example 2.1.10. Let the continuous-type random variables X and Y have the joint pdf

$$f(x, y) = \begin{cases} e^{-y} & 0 < x < y < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

The reader should sketch the space of (X, Y) . The mgf of this joint distribution is

$$\begin{aligned} M(t_1, t_2) &= \int_0^\infty \left[\int_x^\infty \exp(t_1 x + t_2 y - y) dy \right] dx \\ &= \frac{1}{(1 - t_1 - t_2)(1 - t_2)}, \end{aligned}$$

provided that $t_1 + t_2 < 1$ and $t_2 < 1$. Furthermore, the moment-generating functions of the marginal distributions of X and Y are, respectively,

$$\begin{aligned} M(t_1, 0) &= \frac{1}{1 - t_1}, \quad t_1 < 1 \\ M(0, t_2) &= \frac{1}{(1 - t_2)^2}, \quad t_2 < 1. \end{aligned}$$

These moment-generating functions are, of course, respectively, those of the marginal probability density functions,

$$f_1(x) = \int_x^\infty e^{-y} dy = e^{-x}, \quad 0 < x < \infty,$$

zero elsewhere, and

$$f_2(y) = e^{-y} \int_0^y dx = ye^{-y}, \quad 0 < y < \infty,$$

zero elsewhere. ■

We also need to define the expected value of the random vector itself, but this is not a new concept because it is defined in terms of componentwise expectation:

Definition 2.1.3 (Expected Value of a Random Vector). *Let $\mathbf{X} = (X_1, X_2)'$ be a random vector. Then the **expected value** of \mathbf{X} exists if the expectations of X_1 and X_2 exist. If it exists, then the **expected value** is given by*

$$E[\mathbf{X}] = \begin{bmatrix} E(X_1) \\ E(X_2) \end{bmatrix}. \quad (2.1.14)$$

EXERCISES

2.1.1. Let $f(x_1, x_2) = 4x_1 x_2$, $0 < x_1 < 1$, $0 < x_2 < 1$, zero elsewhere, be the pdf of X_1 and X_2 . Find $P(0 < X_1 < \frac{1}{2}, \frac{1}{4} < X_2 < 1)$, $P(X_1 = X_2)$, $P(X_1 < X_2)$, and $P(X_1 \leq X_2)$.

Hint: Recall that $P(X_1 = X_2)$ would be the volume under the surface $f(x_1, x_2) = 4x_1 x_2$ and above the line segment $0 < x_1 = x_2 < 1$ in the $x_1 x_2$ -plane.

2.1.2. Let $A_1 = \{(x, y) : x \leq 2, y \leq 4\}$, $A_2 = \{(x, y) : x \leq 2, y \leq 1\}$, $A_3 = \{(x, y) : x \leq 0, y \leq 4\}$, and $A_4 = \{(x, y) : x \leq 0, y \leq 1\}$ be subsets of the space \mathcal{A} of two random variables X and Y , which is the entire two-dimensional plane. If $P(A_1) = \frac{7}{8}$, $P(A_2) = \frac{4}{8}$, $P(A_3) = \frac{3}{8}$, and $P(A_4) = \frac{2}{8}$, find $P(A_5)$, where $A_5 = \{(x, y) : 0 < x \leq 2, 1 < y \leq 4\}$.

2.1.3. Let $F(x, y)$ be the distribution function of X and Y . For all real constants $a < b$, $c < d$, show that $P(a < X \leq b, c < Y \leq d) = F(b, d) - F(b, c) - F(a, d) + F(a, c)$.

2.1.4. Show that the function $F(x, y)$ that is equal to 1 provided that $x + 2y \geq 1$, and that is equal to zero provided that $x + 2y < 1$, cannot be a distribution function of two random variables.

Hint: Find four numbers $a < b$, $c < d$, so that

$$F(b, d) - F(a, d) - F(b, c) + F(a, c)$$

is less than zero.

2.1.5. Given that the nonnegative function $g(x)$ has the property that

$$\int_0^\infty g(x) dx = 1,$$

show that

$$f(x_1, x_2) = \frac{2g(\sqrt{x_1^2 + x_2^2})}{\pi \sqrt{x_1^2 + x_2^2}}, \quad 0 < x_1 < \infty, 0 < x_2 < \infty,$$

zero elsewhere, satisfies the conditions for a pdf of two continuous-type random variables X_1 and X_2 .

Hint: Use polar coordinates.

2.1.6. Consider Example 2.1.3.

- (a) Show that $P(a < X < b, c < Y < d) = (\exp\{-a^2\} - \exp\{-b^2\})(\exp\{-c^2\} - \exp\{-d^2\})$.
- (b) Using Part (a) and the notation in Example 2.1.3, show that $P[(X, Y) \in A] = 0.1879$ while $P[(X, Y) \in B] = 0.0026$.
- (c) Show that the following R program computes $P(a < X < b, c < Y < d)$. Then use it to compute the probabilities in Part (b).

```
plifetime <- function(a,b,c,d)
  {(exp(-a^2) - exp(-b^2))*(exp(-c^2) - exp(-d^2))}
```

2.1.7. Let $f(x, y) = e^{-x-y}$, $0 < x < \infty$, $0 < y < \infty$, zero elsewhere, be the pdf of X and Y . Then if $Z = X + Y$, compute $P(Z \leq 0)$, $P(Z \leq 6)$, and, more generally, $P(Z \leq z)$, for $0 < z < \infty$. What is the pdf of Z ?

2.1.8. Let X and Y have the pdf $f(x, y) = 1$, $0 < x < 1$, $0 < y < 1$, zero elsewhere. Find the cdf and pdf of the product $Z = XY$.

2.1.9. Let 13 cards be taken, at random and without replacement, from an ordinary deck of playing cards. If X is the number of spades in these 13 cards, find the pmf of X . If, in addition, Y is the number of hearts in these 13 cards, find the probability $P(X = 2, Y = 5)$. What is the joint pmf of X and Y ?

2.1.10. Let the random variables X_1 and X_2 have the joint pmf described as follows:

(x_1, x_2)	(0, 0)	(0, 1)	(0, 2)	(1, 0)	(1, 1)	(1, 2)
$p(x_1, x_2)$	$\frac{2}{12}$	$\frac{3}{12}$	$\frac{2}{12}$	$\frac{2}{12}$	$\frac{2}{12}$	$\frac{1}{12}$

and $p(x_1, x_2)$ is equal to zero elsewhere.

- (a) Write these probabilities in a rectangular array as in Example 2.1.4, recording each marginal pdf in the “margins.”
- (b) What is $P(X_1 + X_2 = 1)$?

2.1.11. Let X_1 and X_2 have the joint pdf $f(x_1, x_2) = 15x_1^2x_2$, $0 < x_1 < x_2 < 1$, zero elsewhere. Find the marginal pdfs and compute $P(X_1 + X_2 \leq 1)$.

Hint: Graph the space X_1 and X_2 and carefully choose the limits of integration in determining each marginal pdf.

2.1.12. Let X_1, X_2 be two random variables with the joint pmf $p(x_1, x_2)$, $(x_1, x_2) \in \mathcal{S}$, where \mathcal{S} is the support of X_1, X_2 . Let $Y = g(X_1, X_2)$ be a function such that

$$\sum_{(x_1, x_2) \in \mathcal{S}} |g(x_1, x_2)| p(x_1, x_2) < \infty.$$

By following the proof of Theorem 1.8.1, show that

$$E(Y) = \sum_{(x_1, x_2) \in \mathcal{S}} g(x_1, x_2) p(x_1, x_2).$$

2.1.13. Let X_1, X_2 be two random variables with the joint pmf $p(x_1, x_2) = (x_1 + x_2)/12$, for $x_1 = 1, 2$, $x_2 = 1, 2$, zero elsewhere. Compute $E(X_1)$, $E(X_1^2)$, $E(X_2)$, $E(X_2^2)$, and $E(X_1X_2)$. Is $E(X_1X_2) = E(X_1)E(X_2)$? Find $E(2X_1 - 6X_2^2 + 7X_1X_2)$.

2.1.14. Let X_1, X_2 be two random variables with joint pdf $f(x_1, x_2) = 4x_1x_2$, $0 < x_1 < 1$, $0 < x_2 < 1$, zero elsewhere. Compute $E(X_1)$, $E(X_1^2)$, $E(X_2)$, $E(X_2^2)$, and $E(X_1X_2)$. Is $E(X_1X_2) = E(X_1)E(X_2)$? Find $E(3X_2 - 2X_1^2 + 6X_1X_2)$.

2.1.15. Let X_1, X_2 be two random variables with joint pmf $p(x_1, x_2) = (1/2)^{x_1+x_2}$, for $1 \leq x_i < \infty$, $i = 1, 2$, where x_1 and x_2 are integers, zero elsewhere. Determine the joint mgf of X_1, X_2 . Show that $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$.

2.1.16. Let X_1, X_2 be two random variables with joint pdf $f(x_1, x_2) = x_1 \exp\{-x_2\}$, for $0 < x_1 < x_2 < \infty$, zero elsewhere. Determine the joint mgf of X_1, X_2 . Does $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$?

2.1.17. Let X and Y have the joint pdf $f(x, y) = 6(1 - x - y)$, $x + y < 1$, $0 < x$, $0 < y$, zero elsewhere. Compute $P(2X + 3Y < 1)$ and $E(XY + 2X^2)$.

2.2 Transformations: Bivariate Random Variables

Let (X_1, X_2) be a random vector. Suppose we know the joint distribution of (X_1, X_2) and we seek the distribution of a transformation of (X_1, X_2) , say, $Y = g(X_1, X_2)$. We may be able to obtain the cdf of Y . Another way is to use a transformation as we did for univariate random variables in Sections 1.6 and 1.7. In this section, we extend this theory to random vectors. It is best to discuss the discrete and continuous cases separately. We begin with the discrete case.

There are no essential difficulties involved in a problem like the following. Let $p_{X_1, X_2}(x_1, x_2)$ be the joint pmf of two discrete-type random variables X_1 and X_2 with \mathcal{S} the (two-dimensional) set of points at which $p_{X_1, X_2}(x_1, x_2) > 0$; i.e., \mathcal{S} is the support of (X_1, X_2) . Let $y_1 = u_1(x_1, x_2)$ and $y_2 = u_2(x_1, x_2)$ define a one-to-one transformation that maps \mathcal{S} onto \mathcal{T} . The joint pmf of the two new random variables $Y_1 = u_1(X_1, X_2)$ and $Y_2 = u_2(X_1, X_2)$ is given by

$$p_{Y_1, Y_2}(y_1, y_2) = \begin{cases} p_{X_1, X_2}[w_1(y_1, y_2), w_2(y_1, y_2)] & (y_1, y_2) \in \mathcal{T} \\ 0 & \text{elsewhere,} \end{cases}$$

where $x_1 = w_1(y_1, y_2)$, $x_2 = w_2(y_1, y_2)$ is the single-valued inverse of $y_1 = u_1(x_1, x_2)$, $y_2 = u_2(x_1, x_2)$. From this joint pmf $p_{Y_1, Y_2}(y_1, y_2)$ we may obtain the marginal pmf of Y_1 by summing on y_2 or the marginal pmf of Y_2 by summing on y_1 .

In using this change of variable technique, it should be emphasized that we need two “new” variables to replace the two “old” variables. An example helps explain this technique.

Example 2.2.1. In a large metropolitan area during flu season, suppose that two strains of flu, A and B, are occurring. For a given week, let X_1 and X_2 be the respective number of reported cases of strains A and B with the joint pmf

$$p_{X_1, X_2}(x_1, x_2) = \frac{\mu_1^{x_1} \mu_2^{x_2} e^{-\mu_1} e^{-\mu_2}}{x_1! x_2!}, \quad x_1 = 0, 1, 2, 3, \dots, \quad x_2 = 0, 1, 2, 3, \dots,$$

and is zero elsewhere, where the parameters μ_1 and μ_2 are positive real numbers. Thus the space \mathcal{S} is the set of points (x_1, x_2) , where each of x_1 and x_2 is a non-negative integer. Further, repeatedly using the Maclaurin series for the exponential function,³ we have

$$\begin{aligned} E(X_1) &= e^{-\mu_1} \sum_{x_1=0}^{\infty} x_1 \frac{\mu_1^{x_1}}{x_1!} e^{-\mu_2} \sum_{x_2=0}^{\infty} \frac{\mu_2^{x_2}}{x_2!} \\ &= e^{-\mu_1} \sum_{x_1=1}^{\infty} x_1 \mu_1 \frac{\mu_1^{x_1-1}}{(x_1-1)!} \cdot 1 = \mu_1. \end{aligned}$$

Thus μ_1 is the mean number of cases of Strain A flu reported during a week. Likewise, μ_2 is the mean number of cases of Strain B flu reported during a week.

³See for example the discussion on Taylor series in *Mathematical Comments* as referenced in the Preface.

A random variable of interest is $Y_1 = X_1 + X_2$; i.e., the total number of reported cases of A and B flu during a week. By Theorem 2.1.1, we know $E(Y_1) = \mu_1 + \mu_2$; however, we wish to determine the distribution of Y_1 . If we use the change of variable technique, we need to define a second random variable Y_2 . Because Y_2 is of no interest to us, let us choose it in such a way that we have a simple one-to-one transformation. For this example, we take $Y_2 = X_2$. Then $y_1 = x_1 + x_2$ and $y_2 = x_2$ represent a one-to-one transformation that maps \mathcal{S} onto

$$\mathcal{T} = \{(y_1, y_2) : y_2 = 0, 1, \dots, y_1 \text{ and } y_1 = 0, 1, 2, \dots\}.$$

Note that if $(y_1, y_2) \in \mathcal{T}$, then $0 \leq y_2 \leq y_1$. The inverse functions are given by $x_1 = y_1 - y_2$ and $x_2 = y_2$. Thus the joint pmf of Y_1 and Y_2 is

$$p_{Y_1, Y_2}(y_1, y_2) = \frac{\mu_1^{y_1-y_2} \mu_2^{y_2} e^{-\mu_1-\mu_2}}{(y_1 - y_2)! y_2!}, \quad (y_1, y_2) \in \mathcal{T},$$

and is zero elsewhere. Consequently, the marginal pmf of Y_1 is given by

$$\begin{aligned} p_{Y_1}(y_1) &= \sum_{y_2=0}^{y_1} p_{Y_1, Y_2}(y_1, y_2) \\ &= \frac{e^{-\mu_1-\mu_2}}{y_1!} \sum_{y_2=0}^{y_1} \frac{y_1!}{(y_1 - y_2)! y_2!} \mu_1^{y_1-y_2} \mu_2^{y_2} \\ &= \frac{(\mu_1 + \mu_2)^{y_1} e^{-\mu_1-\mu_2}}{y_1!}, \quad y_1 = 0, 1, 2, \dots, \end{aligned}$$

and is zero elsewhere, where the third equality follows from the binomial expansion. ■

For the continuous case we begin with an example that illustrates the cdf technique.

Example 2.2.2. Consider an experiment in which a person chooses at random a point (X_1, X_2) from the unit square $\mathcal{S} = \{(x_1, x_2) : 0 < x_1 < 1, 0 < x_2 < 1\}$. Suppose that our interest is not in X_1 or in X_2 but in $Z = X_1 + X_2$. Once a suitable probability model has been adopted, we shall see how to find the pdf of Z . To be specific, let the nature of the random experiment be such that it is reasonable to *assume* that the distribution of probability over the unit square is uniform. Then the pdf of X_1 and X_2 may be written

$$f_{X_1, X_2}(x_1, x_2) = \begin{cases} 1 & 0 < x_1 < 1, 0 < x_2 < 1 \\ 0 & \text{elsewhere,} \end{cases} \quad (2.2.1)$$

and this describes the probability model. Now let the cdf of Z be denoted by $F_Z(z) = P(X_1 + X_2 \leq z)$. Then

$$F_Z(z) = \begin{cases} 0 & z < 0 \\ \int_0^z \int_0^{z-x_1} dx_2 dx_1 = \frac{z^2}{2} & 0 \leq z < 1 \\ 1 - \int_{z-1}^1 \int_{z-x_1}^1 dx_2 dx_1 = 1 - \frac{(2-z)^2}{2} & 1 \leq z < 2 \\ 1 & 2 \leq z. \end{cases}$$

Since $F'_Z(z)$ exists for all values of z , the pmf of Z may then be written

$$f_Z(z) = \begin{cases} z & 0 < z < 1 \\ 2 - z & 1 \leq z < 2 \\ 0 & \text{elsewhere.} \end{cases} \quad (2.2.2)$$

In the last example, we used the cdf technique to find the distribution of the transformed random vector. Recall in Chapter 1, Theorem 1.7.1 gave a transformation technique to directly determine the pdf of the transformed random variable for one-to-one transformations. As discussed in Section 4.1 of the accompanying resource *Mathematical Comments*,⁴ this is based on the change-in-variable technique for univariate integration. Further Section 4.2 of this resource shows that a similar change-in-variable technique exists for multiple integration. We now discuss in general the transformation technique for the continuous case based on this theory.

Let (X_1, X_2) have a jointly continuous distribution with pdf $f_{X_1, X_2}(x_1, x_2)$ and support set \mathcal{S} . Consider the transformed random vector $(Y_1, Y_2) = T(X_1, X_2)$ where T is a one-to-one continuous transformation. Let $\mathcal{T} = T(\mathcal{S})$ denote the support of (Y_1, Y_2) . The transformation is depicted in Figure 2.2.1. Rewrite the transformation in terms of its components as $(Y_1, Y_2) = T(X_1, X_2) = (u_1(X_1, X_2), u_2(X_1, X_2))$, where the functions $y_1 = u_1(x_1, x_2)$ and $y_2 = u_2(x_1, x_2)$ define T . Since the transformation is one-to-one, the inverse transformation T^{-1} exists. We write it as $x_1 = w_1(y_1, y_2)$, $x_2 = w_2(y_1, y_2)$. Finally, we need the **Jacobian** of the transformation which is the determinant of order 2 given by

$$J = \begin{vmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{vmatrix}.$$

Note that J plays the role of dx/dy in the univariate case. We assume that these first-order partial derivatives are continuous and that the Jacobian J is not identically equal to zero in \mathcal{T} .

Let B be any region⁵ in \mathcal{T} and let $A = T^{-1}(B)$ as shown in Figure 2.2.1. Because the transformation T is one-to-one, $P[(X_1, X_2) \in A] = P[T(X_1, X_2) \in T(A)] = P[(Y_1, Y_2) \in B]$. Then based on the change-in-variable technique, cited above, we have

$$\begin{aligned} P[(X_1, X_2) \in A] &= \iint_A f_{X_1, X_2}(x_1, x_2) dx_1 dx_2 \\ &= \iint_{T(A)} f_{X_1, X_2}[T^{-1}(y_1, y_2)] |J| dy_1 dy_2 \\ &= \iint_B f_{X_1, X_2}[w_1(y_1, y_2), w_2(y_1, y_2)] |J| dy_1 dy_2. \end{aligned}$$

⁴See the reference for *Mathematical Comments* in the Preface.

⁵Technically an event in the support of (Y_1, Y_2) .

Since B is arbitrary, the last integrand must be the joint pdf of (Y_1, Y_2) . That is the pdf of (Y_1, Y_2) is

$$f_{Y_1, Y_2}(y_1, y_2) = \begin{cases} f_{X_1, X_2}[w_1(y_1, y_2), w_2(y_1, y_2)]|J| & (y_1, y_2) \in \mathcal{T} \\ 0 & \text{elsewhere.} \end{cases} \quad (2.2.3)$$

Several examples of this result are given next.

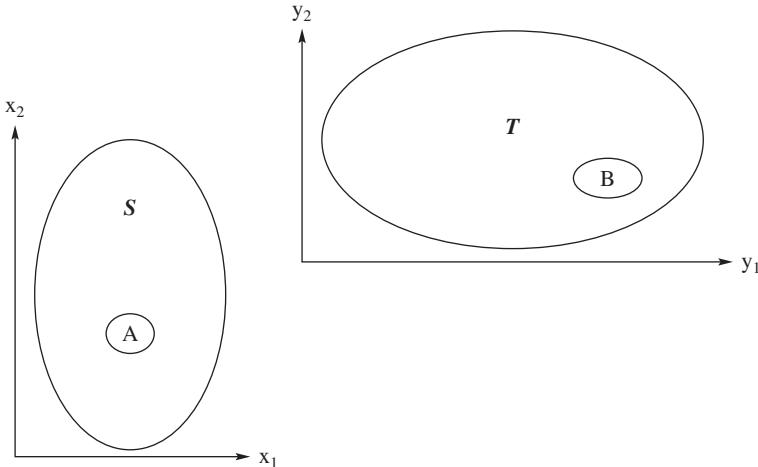

Figure 2.2.1: A general sketch of the supports of (X_1, X_2) , (\mathcal{S}) , and (Y_1, Y_2) , (\mathcal{T}) .

Example 2.2.3. Reconsider Example 2.2.2, where (X_1, X_2) have the uniform distribution over the unit square with the pdf given in expression (2.2.1). The support of (X_1, X_2) is the set $\mathcal{S} = \{(x_1, x_2) : 0 < x_1 < 1, 0 < x_2 < 1\}$ as depicted in Figure 2.2.2.

Suppose $Y_1 = X_1 + X_2$ and $Y_2 = X_1 - X_2$. The transformation is given by

$$\begin{aligned} y_1 &= u_1(x_1, x_2) = x_1 + x_2 \\ y_2 &= u_2(x_1, x_2) = x_1 - x_2. \end{aligned}$$

This transformation is one-to-one. We first determine the set \mathcal{T} in the $y_1 y_2$ -plane that is the mapping of \mathcal{S} under this transformation. Now

$$\begin{aligned} x_1 &= w_1(y_1, y_2) = \frac{1}{2}(y_1 + y_2) \\ x_2 &= w_2(y_1, y_2) = \frac{1}{2}(y_1 - y_2). \end{aligned}$$

To determine the set \mathcal{S} in the $y_1 y_2$ -plane onto which \mathcal{T} is mapped under the transformation, note that the boundaries of \mathcal{S} are transformed as follows into the boundaries

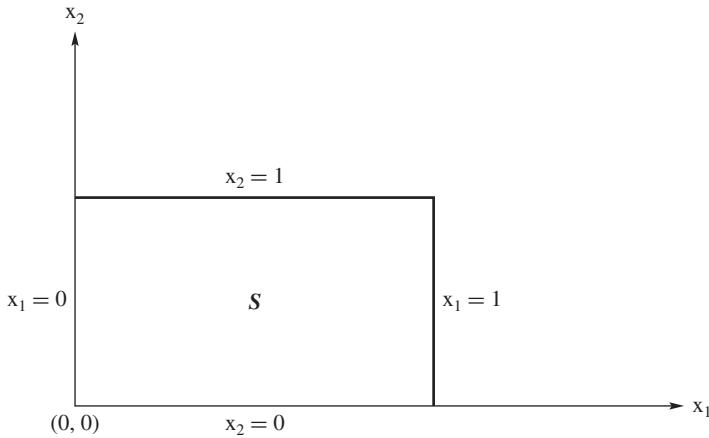

Figure 2.2.2: The support of (X_1, X_2) of Example 2.2.3.

of \mathcal{T} :

$$\begin{aligned}x_1 = 0 &\text{ into } 0 = \frac{1}{2}(y_1 + y_2) \\x_1 = 1 &\text{ into } 1 = \frac{1}{2}(y_1 + y_2) \\x_2 = 0 &\text{ into } 0 = \frac{1}{2}(y_1 - y_2) \\x_2 = 1 &\text{ into } 1 = \frac{1}{2}(y_1 - y_2).\end{aligned}$$

Accordingly, \mathcal{T} is shown in Figure 2.2.3. Next, the Jacobian is given by

$$J = \left| \begin{array}{cc} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{array} \right| = \left| \begin{array}{cc} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} \end{array} \right| = -\frac{1}{2}.$$

Although we suggest transforming the boundaries of \mathcal{S} , others might want to use the inequalities

$$0 < x_1 < 1 \quad \text{and} \quad 0 < x_2 < 1$$

directly. These four inequalities become

$$0 < \frac{1}{2}(y_1 + y_2) < 1 \quad \text{and} \quad 0 < \frac{1}{2}(y_1 - y_2) < 1.$$

It is easy to see that these are equivalent to

$$-y_1 < y_2, \quad y_2 < 2 - y_1, \quad y_2 < y_1 \quad y_1 - 2 < y_2;$$

and they define the set \mathcal{T} .

Hence, the joint pdf of (Y_1, Y_2) is given by

$$f_{Y_1, Y_2}(y_1, y_2) = \begin{cases} f_{X_1, X_2}[\frac{1}{2}(y_1 + y_2), \frac{1}{2}(y_1 - y_2)] |J| = \frac{1}{2} & (y_1, y_2) \in \mathcal{T} \\ 0 & \text{elsewhere.} \end{cases}$$

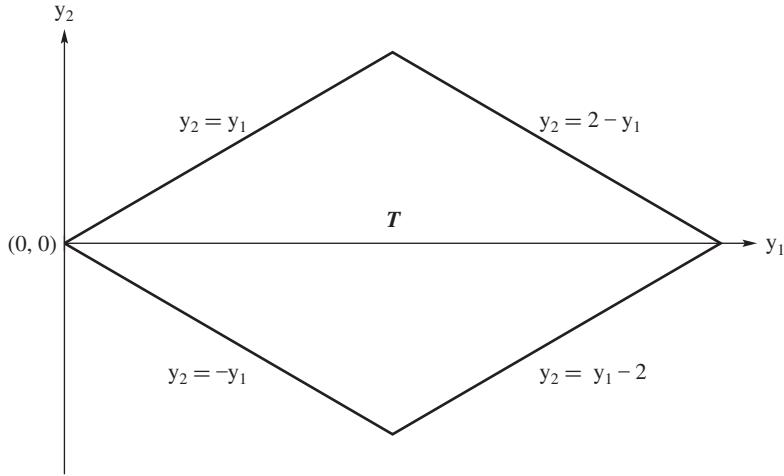

Figure 2.2.3: The support of (Y_1, Y_2) of Example 2.2.3.

The marginal pdf of Y_1 is given by

$$f_{Y_1}(y_1) = \int_{-\infty}^{\infty} f_{Y_1, Y_2}(y_1, y_2) dy_2.$$

If we refer to Figure 2.2.3, we can see that

$$f_{Y_1}(y_1) = \begin{cases} \int_{-y_1}^{y_1} \frac{1}{2} dy_2 = y_1 & 0 < y_1 \leq 1 \\ \int_{y_1-2}^{2-y_1} \frac{1}{2} dy_2 = 2 - y_1 & 1 < y_1 < 2 \\ 0 & \text{elsewhere,} \end{cases}$$

which agrees with expression (2.2.2) of Example 2.2.2. In a similar manner, the marginal pdf $f_{Y_2}(y_2)$ is given by

$$f_{Y_2}(y_2) = \begin{cases} \int_{-y_2}^{y_2+2} \frac{1}{2} dy_1 = y_2 + 1 & -1 < y_2 \leq 0 \\ \int_{y_2}^{2-y_2} \frac{1}{2} dy_1 = 1 - y_2 & 0 < y_2 < 1 \\ 0 & \text{elsewhere.} \end{cases} \blacksquare$$

Example 2.2.4. Let $Y_1 = \frac{1}{2}(X_1 - X_2)$, where X_1 and X_2 have the joint pdf

$$f_{X_1, X_2}(x_1, x_2) = \begin{cases} \frac{1}{4} \exp\left(-\frac{x_1+x_2}{2}\right) & 0 < x_1 < \infty, 0 < x_2 < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Let $Y_2 = X_2$ so that $y_1 = \frac{1}{2}(x_1 - x_2)$, $y_2 = x_2$ or, equivalently, $x_1 = 2y_1 + y_2$, $x_2 = y_2$, define a one-to-one transformation from $\mathcal{S} = \{(x_1, x_2) : 0 < x_1 < \infty, 0 < x_2 < \infty\}$ onto $\mathcal{T} = \{(y_1, y_2) : -2y_1 < y_2 \text{ and } 0 < y_2 < \infty, -\infty < y_1 < \infty\}$. The Jacobian of the transformation is

$$J = \begin{vmatrix} 2 & 1 \\ 0 & 1 \end{vmatrix} = 2;$$

hence the joint pdf of Y_1 and Y_2 is

$$f_{Y_1, Y_2}(y_1, y_2) = \begin{cases} \frac{|2|}{4} e^{-y_1-y_2} & (y_1, y_2) \in \mathcal{T} \\ 0 & \text{elsewhere.} \end{cases}$$

Thus the pdf of Y_1 is given by

$$f_{Y_1}(y_1) = \begin{cases} \int_{-2y_1}^{\infty} \frac{1}{2} e^{-y_1-y_2} dy_2 = \frac{1}{2} e^{y_1} & -\infty < y_1 < 0 \\ \int_0^{\infty} \frac{1}{2} e^{-y_1-y_2} dy_2 = \frac{1}{2} e^{-y_1} & 0 \leq y_1 < \infty, \end{cases}$$

or

$$f_{Y_1}(y_1) = \frac{1}{2} e^{-|y_1|}, \quad -\infty < y_1 < \infty. \quad (2.2.4)$$

Recall from expression (1.9.20) of Chapter 1 that Y_1 has the Laplace distribution. This pdf is also frequently called the **double exponential** pdf. ■

Example 2.2.5. Let X_1 and X_2 have the joint pdf

$$f_{X_1, X_2}(x_1, x_2) = \begin{cases} 10x_1x_2^2 & 0 < x_1 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Suppose $Y_1 = X_1/X_2$ and $Y_2 = X_2$. Hence, the inverse transformation is $x_1 = y_1y_2$ and $x_2 = y_2$, which has the Jacobian

$$J = \begin{vmatrix} y_2 & y_1 \\ 0 & 1 \end{vmatrix} = y_2.$$

The inequalities defining the support \mathcal{S} of (X_1, X_2) become

$$0 < y_1y_2, \quad y_1y_2 < y_2, \quad \text{and} \quad y_2 < 1.$$

These inequalities are equivalent to

$$0 < y_1 < 1 \quad \text{and} \quad 0 < y_2 < 1,$$

which defines the support set \mathcal{T} of (Y_1, Y_2) . Hence, the joint pdf of (Y_1, Y_2) is

$$f_{Y_1, Y_2}(y_1, y_2) = 10y_1y_2y_2^2|y_2| = 10y_1y_2^4, \quad (y_1, y_2) \in \mathcal{T}.$$

The marginal pdfs are

$$f_{Y_1}(y_1) = \int_0^1 10y_1y_2^4 dy_2 = 2y_1, \quad 0 < y_1 < 1,$$

zero elsewhere, and

$$f_{Y_2}(y_2) = \int_0^1 10y_1y_2^4 dy_1 = 5y_2^4, \quad 0 < y_1 < 1,$$

zero elsewhere. ■

In addition to the change-of-variable and cdf techniques for finding distributions of functions of random variables, there is another method, called the **moment generating function (mgf) technique**, which works well for linear functions of random variables. In Subsection 2.1.2, we pointed out that if $Y = g(X_1, X_2)$, then $E(Y)$, if it exists, could be found by

$$E(Y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x_1, x_2) f_{X_1, X_2}(x_1, x_2) dx_1 dx_2$$

in the continuous case, with summations replacing integrals in the discrete case. Certainly, that function $g(X_1, X_2)$ could be $\exp\{tu(X_1, X_2)\}$, so that in reality we would be finding the mgf of the function $Z = u(X_1, X_2)$. If we could then recognize this mgf as belonging to a certain distribution, then Z would have that distribution. We give two illustrations that demonstrate the power of this technique by reconsidering Examples 2.2.1 and 2.2.4.

Example 2.2.6 (Continuation of Example 2.2.1). Here X_1 and X_2 have the joint pmf

$$p_{X_1, X_2}(x_1, x_2) = \begin{cases} \frac{\mu_1^{x_1} \mu_2^{x_2} e^{-\mu_1} e^{-\mu_2}}{x_1! x_2!} & x_1 = 0, 1, 2, 3, \dots, \quad x_2 = 0, 1, 2, 3, \dots \\ 0 & \text{elsewhere,} \end{cases}$$

where μ_1 and μ_2 are fixed positive real numbers. Let $Y = X_1 + X_2$ and consider

$$\begin{aligned} E(e^{tY}) &= \sum_{x_1=0}^{\infty} \sum_{x_2=0}^{\infty} e^{t(x_1+x_2)} p_{X_1, X_2}(x_1, x_2) \\ &= \sum_{x_1=0}^{\infty} e^{tx_1} \frac{\mu_1^{x_1} e^{-\mu_1}}{x_1!} \sum_{x_2=0}^{\infty} e^{tx_2} \frac{\mu_2^{x_2} e^{-\mu_2}}{x_2!} \\ &= \left[e^{-\mu_1} \sum_{x_1=0}^{\infty} \frac{(e^t \mu_1)^{x_1}}{x_1!} \right] \left[e^{-\mu_2} \sum_{x_2=0}^{\infty} \frac{(e^t \mu_2)^{x_2}}{x_2!} \right] \\ &= \left[e^{\mu_1(e^t - 1)} \right] \left[e^{\mu_2(e^t - 1)} \right] \\ &= e^{(\mu_1 + \mu_2)(e^t - 1)}. \end{aligned}$$

Notice that the factors in the brackets in the next-to-last equality are the mgfs of X_1 and X_2 , respectively. Hence, the mgf of Y is the same as that of X_1 except μ_1 has been replaced by $\mu_1 + \mu_2$. Therefore, by the uniqueness of mgfs, the pmf of Y must be

$$p_Y(y) = e^{-(\mu_1 + \mu_2)} \frac{(\mu_1 + \mu_2)^y}{y!}, \quad y = 0, 1, 2, \dots,$$

which is the same pmf that was obtained in Example 2.2.1. ■

Example 2.2.7 (Continuation of Example 2.2.4). Here X_1 and X_2 have the joint pdf

$$f_{X_1, X_2}(x_1, x_2) = \begin{cases} \frac{1}{4} \exp\left(-\frac{x_1+x_2}{2}\right) & 0 < x_1 < \infty, \quad 0 < x_2 < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

So the mgf of $Y = (1/2)(X_1 - X_2)$ is given by

$$\begin{aligned} E(e^{tY}) &= \int_0^\infty \int_0^\infty e^{t(x_1-x_2)/2} \frac{1}{4} e^{-(x_1+x_2)/2} dx_1 dx_2 \\ &= \left[\int_0^\infty \frac{1}{2} e^{-x_1(1-t)/2} dx_1 \right] \left[\int_0^\infty \frac{1}{2} e^{-x_2(1+t)/2} dx_2 \right] \\ &= \left[\frac{1}{1-t} \right] \left[\frac{1}{1+t} \right] = \frac{1}{1-t^2} \end{aligned}$$

provided that $1-t > 0$ and $1+t > 0$; i.e., $-1 < t < 1$. However, the mgf of a Laplace distribution with pdf (1.9.20) is

$$\begin{aligned} \int_{-\infty}^\infty e^{tx} \frac{e^{-|x|}}{2} dx &= \int_{-\infty}^0 \frac{e^{(1+t)x}}{2} dx + \int_0^\infty \frac{e^{(t-1)x}}{2} dx \\ &= \frac{1}{2(1+t)} + \frac{1}{2(1-t)} = \frac{1}{1-t^2}, \end{aligned}$$

provided $-1 < t < 1$. Thus, by the uniqueness of mgfs, Y has a Laplace distribution with pdf (1.9.20). ■

EXERCISES

2.2.1. If $p(x_1, x_2) = (\frac{2}{3})^{x_1+x_2} (\frac{1}{3})^{2-x_1-x_2}$, $(x_1, x_2) = (0, 0), (0, 1), (1, 0), (1, 1)$, zero elsewhere, is the joint pmf of X_1 and X_2 , find the joint pmf of $Y_1 = X_1 - X_2$ and $Y_2 = X_1 + X_2$.

2.2.2. Let X_1 and X_2 have the joint pmf $p(x_1, x_2) = x_1 x_2 / 36$, $x_1 = 1, 2, 3$ and $x_2 = 1, 2, 3$, zero elsewhere. Find first the joint pmf of $Y_1 = X_1 X_2$ and $Y_2 = X_2$, and then find the marginal pmf of Y_1 .

2.2.3. Let X_1 and X_2 have the joint pdf $h(x_1, x_2) = 2e^{-x_1-x_2}$, $0 < x_1 < x_2 < \infty$, zero elsewhere. Find the joint pdf of $Y_1 = 2X_1$ and $Y_2 = X_2 - X_1$.

2.2.4. Let X_1 and X_2 have the joint pdf $h(x_1, x_2) = 8x_1 x_2$, $0 < x_1 < x_2 < 1$, zero elsewhere. Find the joint pdf of $Y_1 = X_1/X_2$ and $Y_2 = X_2$.

Hint: Use the inequalities $0 < y_1 y_2 < y_2 < 1$ in considering the mapping from \mathcal{S} onto \mathcal{T} .

2.2.5. Let X_1 and X_2 be continuous random variables with the joint probability density function $f_{X_1, X_2}(x_1, x_2)$, $-\infty < x_i < \infty$, $i = 1, 2$. Let $Y_1 = X_1 + X_2$ and $Y_2 = X_2$.

(a) Find the joint pdf f_{Y_1, Y_2} .

(b) Show that

$$f_{Y_1}(y_1) = \int_{-\infty}^{\infty} f_{X_1, X_2}(y_1 - y_2, y_2) dy_2, \quad (2.2.5)$$

which is sometimes called the **convolution formula**.

2.2.6. Suppose X_1 and X_2 have the joint pdf $f_{X_1, X_2}(x_1, x_2) = e^{-(x_1+x_2)}$, $0 < x_i < \infty$, $i = 1, 2$, zero elsewhere.

(a) Use formula (2.2.5) to find the pdf of $Y_1 = X_1 + X_2$.

(b) Find the mgf of Y_1 .

2.2.7. Use the formula (2.2.5) to find the pdf of $Y_1 = X_1 + X_2$, where X_1 and X_2 have the joint pdf $f_{X_1, X_2}(x_1, x_2) = 2e^{-(x_1+x_2)}$, $0 < x_1 < x_2 < \infty$, zero elsewhere.

2.2.8. Suppose X_1 and X_2 have the joint pdf

$$f(x_1, x_2) = \begin{cases} e^{-x_1} e^{-x_2} & x_1 > 0, x_2 > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

For constants $w_1 > 0$ and $w_2 > 0$, let $W = w_1 X_1 + w_2 X_2$.

(a) Show that the pdf of W is

$$f_W(w) = \begin{cases} \frac{1}{w_1 - w_2} (e^{-w/w_1} - e^{-w/w_2}) & w > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

(b) Verify that $f_W(w) > 0$ for $w > 0$.

(c) Note that the pdf $f_W(w)$ has an indeterminate form when $w_1 = w_2$. Rewrite $f_W(w)$ using h defined as $w_1 - w_2 = h$. Then use l'Hôpital's rule to show that when $w_1 = w_2$, the pdf is given by $f_W(w) = (w/w_1^2) \exp\{-w/w_1\}$ for $w > 0$ and zero elsewhere.

2.3 Conditional Distributions and Expectations

In Section 2.1 we introduced the joint probability distribution of a pair of random variables. We also showed how to recover the individual (marginal) distributions for the random variables from the joint distribution. In this section, we discuss conditional distributions, i.e., the distribution of one of the random variables when the other has assumed a specific value. We discuss this first for the discrete case, which follows easily from the concept of conditional probability presented in Section 1.4.

Let X_1 and X_2 denote random variables of the discrete type, which have the joint pmf $p_{X_1, X_2}(x_1, x_2)$ that is positive on the support set \mathcal{S} and is zero elsewhere. Let $p_{X_1}(x_1)$ and $p_{X_2}(x_2)$ denote, respectively, the marginal probability mass functions of X_1 and X_2 . Let x_1 be a point in the support of X_1 ; hence, $p_{X_1}(x_1) > 0$. Using the definition of conditional probability, we have

$$P(X_2 = x_2 | X_1 = x_1) = \frac{P(X_1 = x_1, X_2 = x_2)}{P(X_1 = x_1)} = \frac{p_{X_1, X_2}(x_1, x_2)}{p_{X_1}(x_1)}$$

for all x_2 in the support \mathcal{S}_{X_2} of X_2 . Define this function as

$$p_{X_2|X_1}(x_2|x_1) = \frac{p_{X_1, X_2}(x_1, x_2)}{p_{X_1}(x_1)}, \quad x_2 \in \mathcal{S}_{X_2}. \quad (2.3.1)$$

For any fixed x_1 with $p_{X_1}(x_1) > 0$, this function $p_{X_2|X_1}(x_2|x_1)$ satisfies the conditions of being a pmf of the discrete type because $p_{X_2|X_1}(x_2|x_1)$ is nonnegative and

$$\begin{aligned}\sum_{x_2} p_{X_2|X_1}(x_2|x_1) &= \sum_{x_2} \frac{p_{X_1, X_2}(x_1, x_2)}{p_{X_1}(x_1)} \\ &= \frac{1}{p_{X_1}(x_1)} \sum_{x_2} p_{X_1, X_2}(x_1, x_2) = \frac{p_{X_1}(x_1)}{p_{X_1}(x_1)} = 1.\end{aligned}$$

We call $p_{X_2|X_1}(x_2|x_1)$ the **conditional pmf** of the discrete type of random variable X_2 , given that the discrete type of random variable $X_1 = x_1$. In a similar manner, provided $x_2 \in S_{X_2}$, we define the symbol $p_{X_1|X_2}(x_1|x_2)$ by the relation

$$p_{X_1|X_2}(x_1|x_2) = \frac{p_{X_1, X_2}(x_1, x_2)}{p_{X_2}(x_2)}, \quad x_1 \in S_{X_1},$$

and we call $p_{X_1|X_2}(x_1|x_2)$ the conditional pmf of the discrete type of random variable X_1 , given that the discrete type of random variable $X_2 = x_2$. We often abbreviate $p_{X_1|X_2}(x_1|x_2)$ by $p_{1|2}(x_1|x_2)$ and $p_{X_2|X_1}(x_2|x_1)$ by $p_{2|1}(x_2|x_1)$. Similarly, $p_1(x_1)$ and $p_2(x_2)$ are used to denote the respective marginal pmfs.

Now let X_1 and X_2 denote random variables of the continuous type and have the joint pdf $f_{X_1, X_2}(x_1, x_2)$ and the marginal probability density functions $f_{X_1}(x_1)$ and $f_{X_2}(x_2)$, respectively. We use the results of the preceding paragraph to motivate a definition of a conditional pdf of a continuous type of random variable. When $f_{X_1}(x_1) > 0$, we define the symbol $f_{X_2|X_1}(x_2|x_1)$ by the relation

$$f_{X_2|X_1}(x_2|x_1) = \frac{f_{X_1, X_2}(x_1, x_2)}{f_{X_1}(x_1)}. \quad (2.3.2)$$

In this relation, x_1 is to be thought of as having a fixed (but any fixed) value for which $f_{X_1}(x_1) > 0$. It is evident that $f_{X_2|X_1}(x_2|x_1)$ is nonnegative and that

$$\begin{aligned}\int_{-\infty}^{\infty} f_{X_2|X_1}(x_2|x_1) dx_2 &= \int_{-\infty}^{\infty} \frac{f_{X_1, X_2}(x_1, x_2)}{f_{X_1}(x_1)} dx_2 \\ &= \frac{1}{f_{X_1}(x_1)} \int_{-\infty}^{\infty} f_{X_1, X_2}(x_1, x_2) dx_2 \\ &= \frac{1}{f_{X_1}(x_1)} f_{X_1}(x_1) = 1.\end{aligned}$$

That is, $f_{X_2|X_1}(x_2|x_1)$ has the properties of a pdf of one continuous type of random variable. It is called the **conditional pdf** of the continuous type of random variable X_2 , given that the continuous type of random variable X_1 has the value x_1 . When $f_{X_2}(x_2) > 0$, the conditional pdf of the continuous random variable X_1 , given that the continuous type of random variable X_2 has the value x_2 , is defined by

$$f_{X_1|X_2}(x_1|x_2) = \frac{f_{X_1, X_2}(x_1, x_2)}{f_{X_2}(x_2)}, \quad f_{X_2}(x_2) > 0.$$

We often abbreviate these conditional pdfs by $f_{1|2}(x_1|x_2)$ and $f_{2|1}(x_2|x_1)$, respectively. Similarly, $f_1(x_1)$ and $f_2(x_2)$ are used to denote the respective marginal pdfs.

Since each of $f_{2|1}(x_2|x_1)$ and $f_{1|2}(x_1|x_2)$ is a pdf of one random variable, each has all the properties of such a pdf. Thus we can compute probabilities and mathematical expectations. If the random variables are of the continuous type, the probability

$$P(a < X_2 < b | X_1 = x_1) = \int_a^b f_{2|1}(x_2|x_1) dx_2$$

is called “the conditional probability that $a < X_2 < b$, given that $X_1 = x_1$.” If there is no ambiguity, this may be written in the form $P(a < X_2 < b | x_1)$. Similarly, the conditional probability that $c < X_1 < d$, given $X_2 = x_2$, is

$$P(c < X_1 < d | X_2 = x_2) = \int_c^d f_{1|2}(x_1|x_2) dx_1.$$

If $u(X_2)$ is a function of X_2 , the **conditional expectation** of $u(X_2)$, given that $X_1 = x_1$, if it exists, is given by

$$E[u(X_2)|x_1] = \int_{-\infty}^{\infty} u(x_2) f_{2|1}(x_2|x_1) dx_2.$$

Note that $E[u(X_2)|x_1]$ is a function of x_1 . If they do exist, then $E(X_2|x_1)$ is the mean and $E\{[X_2 - E(X_2|x_1)]^2|x_1\}$ is the **conditional variance** of the conditional distribution of X_2 , given $X_1 = x_1$, which can be written more simply as $\text{Var}(X_2|x_1)$. It is convenient to refer to these as the “conditional mean” and the “conditional variance” of X_2 , given $X_1 = x_1$. Of course, we have

$$\text{Var}(X_2|x_1) = E(X_2^2|x_1) - [E(X_2|x_1)]^2$$

from an earlier result. In a like manner, the conditional expectation of $u(X_1)$, given $X_2 = x_2$, if it exists, is given by

$$E[u(X_1)|x_2] = \int_{-\infty}^{\infty} u(x_1) f_{1|2}(x_1|x_2) dx_1.$$

With random variables of the discrete type, these conditional probabilities and conditional expectations are computed by using summation instead of integration. An illustrative example follows.

Example 2.3.1. Let X_1 and X_2 have the joint pdf

$$f(x_1, x_2) = \begin{cases} 2 & 0 < x_1 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then the marginal probability density functions are, respectively,

$$f_1(x_1) = \begin{cases} \int_{x_1}^1 2 dx_2 = 2(1 - x_1) & 0 < x_1 < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

and

$$f_2(x_2) = \begin{cases} \int_0^{x_2} 2 dx_1 = 2x_2 & 0 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

The conditional pdf of X_1 , given $X_2 = x_2$, $0 < x_2 < 1$, is

$$f_{1|2}(x_1|x_2) = \begin{cases} \frac{2}{2x_2} = \frac{1}{x_2} & 0 < x_1 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Here the conditional mean and the conditional variance of X_1 , given $X_2 = x_2$, are respectively,

$$\begin{aligned} E(X_1|x_2) &= \int_{-\infty}^{\infty} x_1 f_{1|2}(x_1|x_2) dx_1 \\ &= \int_0^{x_2} x_1 \left(\frac{1}{x_2} \right) dx_1 \\ &= \frac{x_2}{2}, \quad 0 < x_2 < 1, \end{aligned}$$

and

$$\begin{aligned} \text{Var}(X_1|x_2) &= \int_0^{x_2} \left(x_1 - \frac{x_2}{2} \right)^2 \left(\frac{1}{x_2} \right) dx_1 \\ &= \frac{x_2^2}{12}, \quad 0 < x_2 < 1. \end{aligned}$$

Finally, we compare the values of

$$P(0 < X_1 < \frac{1}{2}|X_2 = \frac{3}{4}) \quad \text{and} \quad P(0 < X_1 < \frac{1}{2}).$$

We have

$$P(0 < X_1 < \frac{1}{2}|X_2 = \frac{3}{4}) = \int_0^{1/2} f_{1|2}(x_1|\frac{3}{4}) dx_1 = \int_0^{1/2} (\frac{4}{3}) dx_1 = \frac{2}{3},$$

but

$$P(0 < X_1 < \frac{1}{2}) = \int_0^{1/2} f_1(x_1) dx_1 = \int_0^{1/2} 2(1-x_1) dx_1 = \frac{3}{4}. \blacksquare$$

Since $E(X_2|x_1)$ is a function of x_1 , then $E(X_2|X_1)$ is a random variable with its own distribution, mean, and variance. Let us consider the following illustration of this.

Example 2.3.2. Let X_1 and X_2 have the joint pdf

$$f(x_1, x_2) = \begin{cases} 6x_2 & 0 < x_2 < x_1 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then the marginal pdf of X_1 is

$$f_1(x_1) = \int_0^{x_1} 6x_2 dx_2 = 3x_1^2, \quad 0 < x_1 < 1,$$

zero elsewhere. The conditional pdf of X_2 , given $X_1 = x_1$, is

$$f_{2|1}(x_2|x_1) = \frac{6x_2}{3x_1^2} = \frac{2x_2}{x_1^2}, \quad 0 < x_2 < x_1,$$

zero elsewhere, where $0 < x_1 < 1$. The conditional mean of X_2 , given $X_1 = x_1$, is

$$E(X_2|x_1) = \int_0^{x_1} x_2 \left(\frac{2x_2}{x_1^2} \right) dx_2 = \frac{2}{3}x_1, \quad 0 < x_1 < 1.$$

Now $E(X_2|X_1) = 2X_1/3$ is a random variable, say Y . The cdf of $Y = 2X_1/3$ is

$$G(y) = P(Y \leq y) = P\left(X_1 \leq \frac{3y}{2}\right), \quad 0 \leq y < \frac{2}{3}.$$

From the pdf $f_1(x_1)$, we have

$$G(y) = \int_0^{3y/2} 3x_1^2 dx_1 = \frac{27y^3}{8}, \quad 0 \leq y < \frac{2}{3}.$$

Of course, $G(y) = 0$ if $y < 0$, and $G(y) = 1$ if $\frac{2}{3} < y$. The pdf, mean, and variance of $Y = 2X_1/3$ are

$$g(y) = \frac{81y^2}{8}, \quad 0 \leq y < \frac{2}{3},$$

zero elsewhere,

$$E(Y) = \int_0^{2/3} y \left(\frac{81y^2}{8} \right) dy = \frac{1}{2},$$

and

$$\text{Var}(Y) = \int_0^{2/3} y^2 \left(\frac{81y^2}{8} \right) dy - \frac{1}{4} = \frac{1}{60}.$$

Since the marginal pdf of X_2 is

$$f_2(x_2) = \int_{x_2}^1 6x_2 dx_1 = 6x_2(1 - x_2), \quad 0 < x_2 < 1,$$

zero elsewhere, it is easy to show that $E(X_2) = \frac{1}{2}$ and $\text{Var}(X_2) = \frac{1}{20}$. That is, here

$$E(Y) = E[E(X_2|X_1)] = E(X_2)$$

and

$$\text{Var}(Y) = \text{Var}[E(X_2|X_1)] \leq \text{Var}(X_2). \blacksquare$$

Example 2.3.2 is excellent, as it provides us with the opportunity to apply many of these new definitions as well as review the cdf technique for finding the distribution of a function of a random variable, namely $Y = 2X_1/3$. Moreover, the two observations at the end of this example are no accident because they are true in general.

Theorem 2.3.1. Let (X_1, X_2) be a random vector such that the variance of X_2 is finite. Then,

- (a) $E[E(X_2|X_1)] = E(X_2)$.
- (b) $\text{Var}[E(X_2|X_1)] \leq \text{Var}(X_2)$.

Proof: The proof is for the continuous case. To obtain it for the discrete case, exchange summations for integrals. We first prove (a). Note that

$$\begin{aligned} E(X_2) &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x_2 f(x_1, x_2) dx_2 dx_1 \\ &= \int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} x_2 \frac{f(x_1, x_2)}{f_1(x_1)} dx_2 \right] f_1(x_1) dx_1 \\ &= \int_{-\infty}^{\infty} E(X_2|x_1) f_1(x_1) dx_1 \\ &= E[E(X_2|X_1)], \end{aligned}$$

which is the first result.

Next we show (b). Consider with $\mu_2 = E(X_2)$,

$$\begin{aligned} \text{Var}(X_2) &= E[(X_2 - \mu_2)^2] \\ &= E\{[X_2 - E(X_2|X_1) + E(X_2|X_1) - \mu_2]^2\} \\ &= E\{[X_2 - E(X_2|X_1)]^2\} + E\{[E(X_2|X_1) - \mu_2]^2\} \\ &\quad + 2E\{[X_2 - E(X_2|X_1)][E(X_2|X_1) - \mu_2]\}. \end{aligned}$$

We show that the last term of the right-hand member of the immediately preceding equation is zero. It is equal to

$$\begin{aligned} &2 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [x_2 - E(X_2|x_1)][E(X_2|x_1) - \mu_2] f(x_1, x_2) dx_2 dx_1 \\ &= 2 \int_{-\infty}^{\infty} [E(X_2|x_1) - \mu_2] \left\{ \int_{-\infty}^{\infty} [x_2 - E(X_2|x_1)] \frac{f(x_1, x_2)}{f_1(x_1)} dx_2 \right\} f_1(x_1) dx_1. \end{aligned}$$

But $E(X_2|x_1)$ is the conditional mean of X_2 , given $X_1 = x_1$. Since the expression in the inner braces is equal to

$$E(X_2|x_1) - E(X_2|x_1) = 0,$$

the double integral is equal to zero. Accordingly, we have

$$\text{Var}(X_2) = E\{[X_2 - E(X_2|X_1)]^2\} + E\{[E(X_2|X_1) - \mu_2]^2\}.$$

The first term in the right-hand member of this equation is nonnegative because it is the expected value of a nonnegative function, namely $[X_2 - E(X_2|X_1)]^2$. Since $E[E(X_2|X_1)] = \mu_2$, the second term is $\text{Var}[E(X_2|X_1)]$. Hence we have

$$\text{Var}(X_2) \geq \text{Var}[E(X_2|X_1)],$$

which completes the proof. ■

Intuitively, this result could have this useful interpretation. Both the random variables X_2 and $E(X_2|X_1)$ have the same mean μ_2 . If we did not know μ_2 , we could use either of the two random variables to guess at the unknown μ_2 . Since, however, $\text{Var}(X_2) \geq \text{Var}[E(X_2|X_1)]$, we would put more reliance in $E(X_2|X_1)$ as a guess. That is, if we observe the pair (X_1, X_2) to be (x_1, x_2) , we could prefer to use $E(X_2|x_1)$ to x_2 as a guess at the unknown μ_2 . When studying the use of sufficient statistics in estimation in Chapter 7, we make use of this famous result, attributed to C. R. Rao and David Blackwell.

We finish this section with an example illustrating Theorem 2.3.1.

Example 2.3.3. Let X_1 and X_2 be discrete random variables. Suppose the conditional pmf of X_1 given X_2 and the marginal distribution of X_2 are given by

$$\begin{aligned} p(x_1|x_2) &= \binom{x_2}{x_1} \left(\frac{1}{2}\right)^{x_2}, \quad x_1 = 0, 1, \dots, x_2 \\ p(x_2) &= \frac{2}{3} \left(\frac{1}{3}\right)^{x_2-1}, \quad x_2 = 1, 2, 3 \dots \end{aligned}$$

Let us determine the mgf of X_1 . For fixed x_2 , by the binomial theorem,

$$\begin{aligned} E(e^{tX_1}|x_2) &= \sum_{x_1=0}^{x_2} \binom{x_2}{x_1} e^{tx_1} \left(\frac{1}{2}\right)^{x_2-x_1} \left(\frac{1}{2}\right)^{x_1} \\ &= \left(\frac{1}{2} + \frac{1}{2}e^t\right)^{x_2}. \end{aligned}$$

Hence, by the geometric series and Theorem 2.3.1,

$$\begin{aligned} E(e^{tX_1}) &= E[E(e^{tX_1}|X_2)] \\ &= \sum_{x_2=1}^{\infty} \left(\frac{1}{2} + \frac{1}{2}e^t\right)^{x_2} \frac{2}{3} \left(\frac{1}{3}\right)^{x_2-1} \\ &= \frac{2}{3} \left(\frac{1}{2} + \frac{1}{2}e^t\right) \sum_{x_2=1}^{\infty} \left(\frac{1}{6} + \frac{1}{6}e^t\right)^{x_2-1} \\ &= \frac{2}{3} \left(\frac{1}{2} + \frac{1}{2}e^t\right) \frac{1}{1 - [(1/6) + (1/6)e^t]}, \end{aligned}$$

provided $(1/6) + (1/6)e^t < 1$ or $t < \log 5$ (which includes $t = 0$). ■

EXERCISES

2.3.1. Let X_1 and X_2 have the joint pdf $f(x_1, x_2) = x_1 + x_2$, $0 < x_1 < 1$, $0 < x_2 < 1$, zero elsewhere. Find the conditional mean and variance of X_2 , given $X_1 = x_1$, $0 < x_1 < 1$.

2.3.2. Let $f_{1|2}(x_1|x_2) = c_1 x_1/x_2^2$, $0 < x_1 < x_2$, $0 < x_2 < 1$, zero elsewhere, and $f_2(x_2) = c_2 x_2^4$, $0 < x_2 < 1$, zero elsewhere, denote, respectively, the conditional pdf of X_1 , given $X_2 = x_2$, and the marginal pdf of X_2 . Determine:

- (a) The constants c_1 and c_2 .
- (b) The joint pdf of X_1 and X_2 .
- (c) $P(\frac{1}{4} < X_1 < \frac{1}{2}|X_2 = \frac{5}{8})$.
- (d) $P(\frac{1}{4} < X_1 < \frac{1}{2})$.

2.3.3. Let $f(x_1, x_2) = 21x_1^2x_2^3$, $0 < x_1 < x_2 < 1$, zero elsewhere, be the joint pdf of X_1 and X_2 .

- (a) Find the conditional mean and variance of X_1 , given $X_2 = x_2$, $0 < x_2 < 1$.
- (b) Find the distribution of $Y = E(X_1|X_2)$.
- (c) Determine $E(Y)$ and $\text{Var}(Y)$ and compare these to $E(X_1)$ and $\text{Var}(X_1)$, respectively.

2.3.4. Suppose X_1 and X_2 are random variables of the discrete type that have the joint pmf $p(x_1, x_2) = (x_1 + 2x_2)/18$, $(x_1, x_2) = (1, 1), (1, 2), (2, 1), (2, 2)$, zero elsewhere. Determine the conditional mean and variance of X_2 , given $X_1 = x_1$, for $x_1 = 1$ or 2 . Also, compute $E(3X_1 - 2X_2)$.

2.3.5. Let X_1 and X_2 be two random variables such that the conditional distributions and means exist. Show that:

- (a) $E(X_1 + X_2 | X_2) = E(X_1 | X_2) + X_2$,
- (b) $E(u(X_2) | X_2) = u(X_2)$.

2.3.6. Let the joint pdf of X and Y be given by

$$f(x, y) = \begin{cases} \frac{2}{(1+x+y)^3} & 0 < x < \infty, 0 < y < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

- (a) Compute the marginal pdf of X and the conditional pdf of Y , given $X = x$.
- (b) For a fixed $X = x$, compute $E(1 + x + Y|x)$ and use the result to compute $E(Y|x)$.

2.3.7. Suppose X_1 and X_2 are discrete random variables which have the joint pmf $p(x_1, x_2) = (3x_1 + x_2)/24$, $(x_1, x_2) = (1, 1), (1, 2), (2, 1), (2, 2)$, zero elsewhere. Find the conditional mean $E(X_2|x_1)$, when $x_1 = 1$.

2.3.8. Let X and Y have the joint pdf $f(x, y) = 2 \exp\{-(x + y)\}$, $0 < x < y < \infty$, zero elsewhere. Find the conditional mean $E(Y|x)$ of Y , given $X = x$.

2.3.9. Five cards are drawn at random and without replacement from an ordinary deck of cards. Let X_1 and X_2 denote, respectively, the number of spades and the number of hearts that appear in the five cards.

- (a) Determine the joint pmf of X_1 and X_2 .
- (b) Find the two marginal pmfs.
- (c) What is the conditional pmf of X_2 , given $X_1 = x_1$?

2.3.10. Let X_1 and X_2 have the joint pmf $p(x_1, x_2)$ described as follows:

(x_1, x_2)	(0, 0)	(0, 1)	(1, 0)	(1, 1)	(2, 0)	(2, 1)
$p(x_1, x_2)$	$\frac{1}{18}$	$\frac{3}{18}$	$\frac{4}{18}$	$\frac{3}{18}$	$\frac{6}{18}$	$\frac{1}{18}$

and $p(x_1, x_2)$ is equal to zero elsewhere. Find the two marginal probability mass functions and the two conditional means.

Hint: Write the probabilities in a rectangular array.

2.3.11. Let us choose at random a point from the interval $(0, 1)$ and let the random variable X_1 be equal to the number that corresponds to that point. Then choose a point at random from the interval $(0, x_1)$, where x_1 is the experimental value of X_1 ; and let the random variable X_2 be equal to the number that corresponds to this point.

- (a) Make assumptions about the marginal pdf $f_1(x_1)$ and the conditional pdf $f_{2|1}(x_2|x_1)$.
- (b) Compute $P(X_1 + X_2 \geq 1)$.
- (c) Find the conditional mean $E(X_1|x_2)$.

2.3.12. Let $f(x)$ and $F(x)$ denote, respectively, the pdf and the cdf of the random variable X . The conditional pdf of X , given $X > x_0$, x_0 a fixed number, is defined by $f(x|X > x_0) = f(x)/[1 - F(x_0)]$, $x_0 < x$, zero elsewhere. This kind of conditional pdf finds application in a problem of time until death, given survival until time x_0 .

- (a) Show that $f(x|X > x_0)$ is a pdf.
- (b) Let $f(x) = e^{-x}$, $0 < x < \infty$, and zero elsewhere. Compute $P(X > 2|X > 1)$.

2.4 Independent Random Variables

Let X_1 and X_2 denote the random variables of the continuous type that have the joint pdf $f(x_1, x_2)$ and marginal probability density functions $f_1(x_1)$ and $f_2(x_2)$, respectively. In accordance with the definition of the conditional pdf $f_{2|1}(x_2|x_1)$, we may write the joint pdf $f(x_1, x_2)$ as

$$f(x_1, x_2) = f_{2|1}(x_2|x_1)f_1(x_1).$$

Suppose that we have an instance where $f_{2|1}(x_2|x_1)$ does not depend upon x_1 . Then the marginal pdf of X_2 is, for random variables of the continuous type,

$$\begin{aligned} f_2(x_2) &= \int_{-\infty}^{\infty} f_{2|1}(x_2|x_1) f_1(x_1) dx_1 \\ &= f_{2|1}(x_2|x_1) \int_{-\infty}^{\infty} f_1(x_1) dx_1 \\ &= f_{2|1}(x_2|x_1). \end{aligned}$$

Accordingly,

$$f_2(x_2) = f_{2|1}(x_2|x_1) \quad \text{and} \quad f(x_1, x_2) = f_1(x_1)f_2(x_2),$$

when $f_{2|1}(x_2|x_1)$ does not depend upon x_1 . That is, if the conditional distribution of X_2 , given $X_1 = x_1$, is independent of any assumption about x_1 , then $f(x_1, x_2) = f_1(x_1)f_2(x_2)$.

The same discussion applies to the discrete case too, which we summarize in parentheses in the following definition.

Definition 2.4.1 (Independence). *Let the random variables X_1 and X_2 have the joint pdf $f(x_1, x_2)$ [joint pmf $p(x_1, x_2)$] and the marginal pdfs [pmfs] $f_1(x_1)$ [$p_1(x_1)$] and $f_2(x_2)$ [$p_2(x_2)$], respectively. The random variables X_1 and X_2 are said to be **independent** if, and only if, $f(x_1, x_2) \equiv f_1(x_1)f_2(x_2)$ [$p(x_1, x_2) \equiv p_1(x_1)p_2(x_2)$]. Random variables that are not independent are said to be **dependent**.*

Remark 2.4.1. Two comments should be made about the preceding definition. First, the product of two positive functions $f_1(x_1)f_2(x_2)$ means a function that is positive on the product space. That is, if $f_1(x_1)$ and $f_2(x_2)$ are positive on, and only on, the respective spaces \mathcal{S}_1 and \mathcal{S}_2 , then the product of $f_1(x_1)$ and $f_2(x_2)$ is positive on, and only on, the product space $\mathcal{S} = \{(x_1, x_2) : x_1 \in \mathcal{S}_1, x_2 \in \mathcal{S}_2\}$. For instance, if $\mathcal{S}_1 = \{x_1 : 0 < x_1 < 1\}$ and $\mathcal{S}_2 = \{x_2 : 0 < x_2 < 3\}$, then $\mathcal{S} = \{(x_1, x_2) : 0 < x_1 < 1, 0 < x_2 < 3\}$. The second remark pertains to the identity. The identity in Definition 2.4.1 should be interpreted as follows. There may be certain points $(x_1, x_2) \in \mathcal{S}$ at which $f(x_1, x_2) \neq f_1(x_1)f_2(x_2)$. However, if A is the set of points (x_1, x_2) at which the equality does not hold, then $P(A) = 0$. In subsequent theorems and the subsequent generalizations, a product of nonnegative functions and an identity should be interpreted in an analogous manner. ■

Example 2.4.1. Suppose an urn contains 10 blue, 8 red, and 7 yellow balls that are the same except for color. Suppose 4 balls are drawn without replacement. Let X and Y be the number of red and blue balls drawn, respectively. The joint pmf of (X, Y) is

$$p(x, y) = \frac{\binom{10}{x} \binom{8}{y} \binom{7}{4-x-y}}{\binom{25}{4}}, \quad 0 \leq x, y \leq 4; x + y \leq 4.$$

Since $X + Y \leq 4$, it would seem that X and Y are dependent. To see that this is true by definition, we first find the marginal pmf's which are:

$$\begin{aligned} p_X(x) &= \frac{\binom{10}{x} \binom{15}{4-x}}{\binom{25}{4}}, \quad 0 \leq x \leq 4; \\ p_Y(y) &= \frac{\binom{8}{y} \binom{17}{4-y}}{\binom{25}{4}}, \quad 0 \leq y \leq 4. \end{aligned}$$

To show dependence, we need to find only one point in the support of (X_1, X_2) where the joint pmf does not factor into the product of the marginal pmf's. Suppose we select the point $x = 1$ and $y = 1$. Then, using R for calculation, we compute (to 4 places):

$$\begin{aligned} p(1, 1) &= 10 \cdot 8 \cdot \binom{7}{2} / \binom{25}{4} = 0.1328 \\ p_X(1) &= 10 \binom{15}{3} / \binom{25}{4} = 0.3597 \\ p_Y(1) &= 8 \binom{17}{3} / \binom{25}{4} = 0.4300. \end{aligned}$$

Since $0.1328 \neq 0.1547 = 0.3597 \cdot 0.4300$, X and Y are dependent random variables. ■

Example 2.4.2. Let the joint pdf of X_1 and X_2 be

$$f(x_1, x_2) = \begin{cases} x_1 + x_2 & 0 < x_1 < 1, \quad 0 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

We show that X_1 and X_2 are dependent. Here the marginal probability density functions are

$$f_1(x_1) = \begin{cases} \int_{-\infty}^{\infty} f(x_1, x_2) dx_2 = \int_0^1 (x_1 + x_2) dx_2 = x_1 + \frac{1}{2} & 0 < x_1 < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

and

$$f_2(x_2) = \begin{cases} \int_{-\infty}^{\infty} f(x_1, x_2) dx_1 = \int_0^1 (x_1 + x_2) dx_1 = \frac{1}{2} + x_2 & 0 < x_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Since $f(x_1, x_2) \neq f_1(x_1)f_2(x_2)$, the random variables X_1 and X_2 are dependent. ■

The following theorem makes it possible to assert that the random variables X_1 and X_2 of Example 2.4.2 are dependent, without computing the marginal probability density functions.

Theorem 2.4.1. *Let the random variables X_1 and X_2 have supports \mathcal{S}_1 and \mathcal{S}_2 , respectively, and have the joint pdf $f(x_1, x_2)$. Then X_1 and X_2 are independent if*

and only if $f(x_1, x_2)$ can be written as a product of a nonnegative function of x_1 and a nonnegative function of x_2 . That is,

$$f(x_1, x_2) \equiv g(x_1)h(x_2),$$

where $g(x_1) > 0$, $x_1 \in \mathcal{S}_1$, zero elsewhere, and $h(x_2) > 0$, $x_2 \in \mathcal{S}_2$, zero elsewhere.

Proof. If X_1 and X_2 are independent, then $f(x_1, x_2) \equiv f_1(x_1)f_2(x_2)$, where $f_1(x_1)$ and $f_2(x_2)$ are the marginal probability density functions of X_1 and X_2 , respectively. Thus the condition $f(x_1, x_2) \equiv g(x_1)h(x_2)$ is fulfilled.

Conversely, if $f(x_1, x_2) \equiv g(x_1)h(x_2)$, then, for random variables of the continuous type, we have

$$f_1(x_1) = \int_{-\infty}^{\infty} g(x_1)h(x_2) dx_2 = g(x_1) \int_{-\infty}^{\infty} h(x_2) dx_2 = c_1 g(x_1)$$

and

$$f_2(x_2) = \int_{-\infty}^{\infty} g(x_1)h(x_2) dx_1 = h(x_2) \int_{-\infty}^{\infty} g(x_1) dx_1 = c_2 h(x_2),$$

where c_1 and c_2 are constants, not functions of x_1 or x_2 . Moreover, $c_1 c_2 = 1$ because

$$1 = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} g(x_1)h(x_2) dx_1 dx_2 = \left[\int_{-\infty}^{\infty} g(x_1) dx_1 \right] \left[\int_{-\infty}^{\infty} h(x_2) dx_2 \right] = c_2 c_1.$$

These results imply that

$$f(x_1, x_2) \equiv g(x_1)h(x_2) \equiv c_1 g(x_1)c_2 h(x_2) \equiv f_1(x_1)f_2(x_2).$$

Accordingly, X_1 and X_2 are independent. ■

This theorem is true for the discrete case also. Simply replace the joint pdf by the joint pmf. For instance, the discrete random variables X and Y of Example 2.4.1 are immediately seen to be dependent because the support of (X, Y) is not a product space.

Next, consider the joint distribution of the continuous random vector (X, Y) given in Example 2.1.3. The joint pdf is

$$f(x, y) = 4xe^{-x^2}ye^{-y^2}, \quad x > 0, y > 0.$$

which is a product of a nonnegative function of x and a nonnegative function of y . Further, the joint support is a product space. Hence, X and Y are independent random variables.

Example 2.4.3. Let the pdf of the random variable X_1 and X_2 be $f(x_1, x_2) = 8x_1x_2$, $0 < x_1 < x_2 < 1$, zero elsewhere. The formula $8x_1x_2$ might suggest to some that X_1 and X_2 are independent. However, if we consider the space $\mathcal{S} = \{(x_1, x_2) : 0 < x_1 < x_2 < 1\}$, we see that it is not a product space. This should make it clear that, in general, X_1 and X_2 must be dependent if the space of positive probability density of X_1 and X_2 is bounded by a curve that is neither a horizontal nor a vertical line. ■

Instead of working with pdfs (or pmfs) we could have presented independence in terms of cumulative distribution functions. The following theorem shows the equivalence.

Theorem 2.4.2. *Let (X_1, X_2) have the joint cdf $F(x_1, x_2)$ and let X_1 and X_2 have the marginal cdfs $F_1(x_1)$ and $F_2(x_2)$, respectively. Then X_1 and X_2 are independent if and only if*

$$F(x_1, x_2) = F_1(x_1)F_2(x_2) \quad \text{for all } (x_1, x_2) \in R^2. \quad (2.4.1)$$

Proof: We give the proof for the continuous case. Suppose expression (2.4.1) holds. Then the mixed second partial is

$$\frac{\partial^2}{\partial x_1 \partial x_2} F(x_1, x_2) = f_1(x_1)f_2(x_2).$$

Hence, X_1 and X_2 are independent. Conversely, suppose X_1 and X_2 are independent. Then by the definition of the joint cdf,

$$\begin{aligned} F(x_1, x_2) &= \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} f_1(w_1)f_2(w_2) dw_2 dw_1 \\ &= \int_{-\infty}^{x_1} f_1(w_1) dw_1 \cdot \int_{-\infty}^{x_2} f_2(w_2) dw_2 = F_1(x_1)F_2(x_2). \end{aligned}$$

Hence, condition (2.4.1) is true. ■

We now give a theorem that frequently simplifies the calculations of probabilities of events that involves independent variables.

Theorem 2.4.3. *The random variables X_1 and X_2 are independent random variables if and only if the following condition holds,*

$$P(a < X_1 \leq b, c < X_2 \leq d) = P(a < X_1 \leq b)P(c < X_2 \leq d) \quad (2.4.2)$$

for every $a < b$ and $c < d$, where a, b, c , and d are constants.

Proof: If X_1 and X_2 are independent, then an application of the last theorem and expression (2.1.2) shows that

$$\begin{aligned} P(a < X_1 \leq b, c < X_2 \leq d) &= F(b, d) - F(a, d) - F(b, c) + F(a, c) \\ &= F_1(b)F_2(d) - F_1(a)F_2(d) - F_1(b)F_2(c) \\ &\quad + F_1(a)F_2(c) \\ &= [F_1(b) - F_1(a)][F_2(d) - F_2(c)], \end{aligned}$$

which is the right side of expression (2.4.2). Conversely, condition (2.4.2) implies that the joint cdf of (X_1, X_2) factors into a product of the marginal cdfs, which in turn by Theorem 2.4.2 implies that X_1 and X_2 are independent. ■

Example 2.4.4 (Example 2.4.2, Continued). Independence is necessary for condition (2.4.2). For example, consider the dependent variables X_1 and X_2 of Example 2.4.2. For these random variables, we have

$$P(0 < X_1 < \frac{1}{2}, 0 < X_2 < \frac{1}{2}) = \int_0^{1/2} \int_0^{1/2} (x_1 + x_2) dx_1 dx_2 = \frac{1}{8},$$

whereas

$$P(0 < X_1 < \frac{1}{2}) = \int_0^{1/2} (x_1 + \frac{1}{2}) dx_1 = \frac{3}{8}$$

and

$$P(0 < X_2 < \frac{1}{2}) = \int_0^{1/2} (\frac{1}{2} + x_1) dx_2 = \frac{3}{8}.$$

Hence, condition (2.4.2) does not hold. ■

Not merely are calculations of some probabilities usually simpler when we have independent random variables, but many expectations, including certain moment generating functions, have comparably simpler computations. The following result proves so useful that we state it in the form of a theorem.

Theorem 2.4.4. Suppose X_1 and X_2 are independent and that $E(u(X_1))$ and $E(v(X_2))$ exist. Then

$$E[u(X_1)v(X_2)] = E[u(X_1)]E[v(X_2)].$$

Proof. We give the proof in the continuous case. The independence of X_1 and X_2 implies that the joint pdf of X_1 and X_2 is $f_1(x_1)f_2(x_2)$. Thus we have, by definition of expectation,

$$\begin{aligned} E[u(X_1)v(X_2)] &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} u(x_1)v(x_2)f_1(x_1)f_2(x_2) dx_1 dx_2 \\ &= \left[\int_{-\infty}^{\infty} u(x_1)f_1(x_1) dx_1 \right] \left[\int_{-\infty}^{\infty} v(x_2)f_2(x_2) dx_2 \right] \\ &= E[u(X_1)]E[v(X_2)]. \end{aligned}$$

Hence, the result is true. ■

Upon taking the functions $u(\cdot)$ and $v(\cdot)$ to be the identity functions in Theorem 2.4.4, we have that for independent random variables X_1 and X_2 ,

$$E(X_1X_2) = E(X_1)E(X_2). \quad (2.4.3)$$

We next prove a very useful theorem about independent random variables. The proof of the theorem relies heavily upon our assertion that an mgf, when it exists, is unique and that it uniquely determines the distribution of probability.

Theorem 2.4.5. Suppose the joint mgf, $M(t_1, t_2)$, exists for the random variables X_1 and X_2 . Then X_1 and X_2 are independent if and only if

$$M(t_1, t_2) = M(t_1, 0)M(0, t_2);$$

that is, the joint mgf is identically equal to the product of the marginal mgfs.

Proof. If X_1 and X_2 are independent, then

$$\begin{aligned} M(t_1, t_2) &= E(e^{t_1 X_1 + t_2 X_2}) \\ &= E(e^{t_1 X_1} e^{t_2 X_2}) \\ &= E(e^{t_1 X_1}) E(e^{t_2 X_2}) \\ &= M(t_1, 0) M(0, t_2). \end{aligned}$$

Thus the independence of X_1 and X_2 implies that the mgf of the joint distribution factors into the product of the moment-generating functions of the two marginal distributions.

Suppose next that the mgf of the joint distribution of X_1 and X_2 is given by $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$. Now X_1 has the unique mgf, which, in the continuous case, is given by

$$M(t_1, 0) = \int_{-\infty}^{\infty} e^{t_1 x_1} f_1(x_1) dx_1.$$

Similarly, the unique mgf of X_2 , in the continuous case, is given by

$$M(0, t_2) = \int_{-\infty}^{\infty} e^{t_2 x_2} f_2(x_2) dx_2.$$

Thus we have

$$\begin{aligned} M(t_1, 0)M(0, t_2) &= \left[\int_{-\infty}^{\infty} e^{t_1 x_1} f_1(x_1) dx_1 \right] \left[\int_{-\infty}^{\infty} e^{t_2 x_2} f_2(x_2) dx_2 \right] \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{t_1 x_1 + t_2 x_2} f_1(x_1) f_2(x_2) dx_1 dx_2. \end{aligned}$$

We are given that $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$; so

$$M(t_1, t_2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{t_1 x_1 + t_2 x_2} f_1(x_1) f_2(x_2) dx_1 dx_2.$$

But $M(t_1, t_2)$ is the mgf of X_1 and X_2 . Thus

$$M(t_1, t_2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{t_1 x_1 + t_2 x_2} f(x_1, x_2) dx_1 dx_2.$$

The uniqueness of the mgf implies that the two distributions of probability that are described by $f_1(x_1)f_2(x_2)$ and $f(x_1, x_2)$ are the same. Thus

$$f(x_1, x_2) \equiv f_1(x_1) f_2(x_2).$$

That is, if $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$, then X_1 and X_2 are independent. This completes the proof when the random variables are of the continuous type. With random variables of the discrete type, the proof is made by using summation instead of integration. ■

Example 2.4.5 (Example 2.1.10, Continued). Let (X, Y) be a pair of random variables with the joint pdf

$$f(x, y) = \begin{cases} e^{-y} & 0 < x < y < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

In Example 2.1.10, we showed that the mgf of (X, Y) is

$$\begin{aligned} M(t_1, t_2) &= \int_0^\infty \int_x^\infty \exp(t_1 x + t_2 y - y) dy dx \\ &= \frac{1}{(1-t_1-t_2)(1-t_2)}, \end{aligned}$$

provided that $t_1 + t_2 < 1$ and $t_2 < 1$. Because $M(t_1, t_2) \neq M(t_1, 0)M(t_2, 0)$, the random variables are dependent. ■

Example 2.4.6 (Exercise 2.1.15, Continued). For the random variable X_1 and X_2 defined in Exercise 2.1.15, we showed that the joint mgf is

$$M(t_1, t_2) = \left[\frac{\exp\{t_1\}}{2 - \exp\{t_1\}} \right] \left[\frac{\exp\{t_2\}}{2 - \exp\{t_2\}} \right], \quad t_i < \log 2, i = 1, 2.$$

We showed further that $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$. Hence, X_1 and X_2 are independent random variables. ■

EXERCISES

2.4.1. Show that the random variables X_1 and X_2 with joint pdf

$$f(x_1, x_2) = \begin{cases} 12x_1x_2(1-x_2) & 0 < x_1 < 1, 0 < x_2 < 1 \\ 0 & \text{elsewhere} \end{cases}$$

are independent.

2.4.2. If the random variables X_1 and X_2 have the joint pdf $f(x_1, x_2) = 2e^{-x_1-x_2}$, $0 < x_1 < x_2$, $0 < x_2 < \infty$, zero elsewhere, show that X_1 and X_2 are dependent.

2.4.3. Let $p(x_1, x_2) = \frac{1}{16}$, $x_1 = 1, 2, 3, 4$, and $x_2 = 1, 2, 3, 4$, zero elsewhere, be the joint pmf of X_1 and X_2 . Show that X_1 and X_2 are independent.

2.4.4. Find $P(0 < X_1 < \frac{1}{3}, 0 < X_2 < \frac{1}{3})$ if the random variables X_1 and X_2 have the joint pdf $f(x_1, x_2) = 4x_1(1-x_2)$, $0 < x_1 < 1$, $0 < x_2 < 1$, zero elsewhere.

2.4.5. Find the probability of the union of the events $a < X_1 < b$, $-\infty < X_2 < \infty$, and $-\infty < X_1 < \infty$, $c < X_2 < d$ if X_1 and X_2 are two independent variables with $P(a < X_1 < b) = \frac{2}{3}$ and $P(c < X_2 < d) = \frac{5}{8}$.

2.4.6. If $f(x_1, x_2) = e^{-x_1-x_2}$, $0 < x_1 < \infty$, $0 < x_2 < \infty$, zero elsewhere, is the joint pdf of the random variables X_1 and X_2 , show that X_1 and X_2 are independent and that $M(t_1, t_2) = (1 - t_1)^{-1}(1 - t_2)^{-1}$, $t_2 < 1$, $t_1 < 1$. Also show that

$$E(e^{t(X_1+X_2)}) = (1 - t)^{-2}, \quad t < 1.$$

Accordingly, find the mean and the variance of $Y = X_1 + X_2$.

2.4.7. Let the random variables X_1 and X_2 have the joint pdf $f(x_1, x_2) = 1/\pi$, for $(x_1 - 1)^2 + (x_2 + 2)^2 < 1$, zero elsewhere. Find $f_1(x_1)$ and $f_2(x_2)$. Are X_1 and X_2 independent?

2.4.8. Let X and Y have the joint pdf $f(x, y) = 3x$, $0 < y < x < 1$, zero elsewhere. Are X and Y independent? If not, find $E(X|y)$.

2.4.9. Suppose that a man leaves for work between 8:00 a.m. and 8:30 a.m. and takes between 40 and 50 minutes to get to the office. Let X denote the time of departure and let Y denote the time of travel. If we assume that these random variables are independent and uniformly distributed, find the probability that he arrives at the office before 9:00 a.m.

2.4.10. Let X and Y be random variables with the space consisting of the four points $(0, 0), (1, 1), (1, 0), (1, -1)$. Assign positive probabilities to these four points so that the correlation coefficient is equal to zero. Are X and Y independent?

2.4.11. Two line segments, each of length two units, are placed along the x -axis. The midpoint of the first is between $x = 0$ and $x = 14$ and that of the second is between $x = 6$ and $x = 20$. Assuming independence and uniform distributions for these midpoints, find the probability that the line segments overlap.

2.4.12. Cast a fair die and let $X = 0$ if 1, 2, or 3 spots appear, let $X = 1$ if 4 or 5 spots appear, and let $X = 2$ if 6 spots appear. Do this two independent times, obtaining X_1 and X_2 . Calculate $P(|X_1 - X_2| = 1)$.

2.4.13. For X_1 and X_2 in Example 2.4.6, show that the mgf of $Y = X_1 + X_2$ is $e^{2t}/(2 - e^t)^2$, $t < \log 2$, and then compute the mean and variance of Y .

2.5 The Correlation Coefficient

Let (X, Y) denote a random vector. In the last section, we discussed the concept of independence between X and Y . What if, though, X and Y are dependent and, if so, how are they related? There are many measures of dependence. In this section, we introduce a parameter ρ of the joint distribution of (X, Y) which measures linearity between X and Y . In this section, we assume the existence of all expectations under discussion.

Definition 2.5.1. Let (X, Y) have a joint distribution. Denote the means of X and Y respectively by μ_1 and μ_2 and their respective variances by σ_1^2 and σ_2^2 . The covariance of (X, Y) is denoted by $\text{cov}(X, Y)$ and is defined by the expectation

$$\text{cov}(X, Y) = E[(X - \mu_1)(Y - \mu_2)]. \quad \blacksquare \quad (2.5.1)$$

It follows by the linearity of expectation, Theorem 2.1.1, that the covariance of X and Y can also be expressed as

$$\begin{aligned}\text{cov}(X, Y) &= E(XY - \mu_2 X - \mu_1 Y + \mu_1 \mu_2) \\ &= E(XY) - \mu_2 E(X) - \mu_1 E(Y) + \mu_1 \mu_2 \\ &= E(XY) - \mu_1 \mu_2,\end{aligned}\tag{2.5.2}$$

which is often easier to compute than using the definition, (2.5.1).

The measure that we seek is a standardized (unitless) version of the covariance.

Definition 2.5.2. *If each of σ_1 and σ_2 is positive, then the **correlation coefficient** between X and Y is defined by*

$$\rho = \frac{E[(X - \mu_1)(Y - \mu_2)]}{\sigma_1 \sigma_2} = \frac{\text{cov}(X, Y)}{\sigma_1 \sigma_2}. \blacksquare\tag{2.5.3}$$

It should be noted that the expected value of the product of two random variables is equal to the product of their expectations plus their covariance; that is, $E(XY) = \mu_1 \mu_2 + \text{cov}(X, Y) = \mu_1 \mu_2 + \rho \sigma_1 \sigma_2$.

As illustrations, we present two examples. The first is for a discrete model while the second concerns a continuous model.

Example 2.5.1. Reconsider the random vector (X_1, X_2) of Example 2.1.1 where a fair coin is flipped three times and X_1 is the number of heads on the first two flips while X_2 is the number of heads on all three flips. Recall that Table 2.1.1 contains the marginal distributions of X_1 and X_2 . By symmetry of these pmfs, we have $E(X_1) = 1$ and $E(X_2) = 3/2$. To compute the correlation coefficient of (X_1, X_2) , we next sketch the computation of the required moments:

$$\begin{aligned}E(X_1^2) &= \frac{1}{2} + 2^2 \cdot \frac{1}{4} = \frac{3}{2} \Rightarrow \sigma_1^2 = \frac{3}{2} - 1^2 = \frac{1}{2}; \\ E(X_2^2) &= \frac{3}{8} + 4 \cdot \frac{3}{8} + 9 \cdot \frac{1}{8} = 3 \Rightarrow \sigma_2^2 = 3 - \left(\frac{3}{2}\right)^2 1^2 = \frac{1}{2}; \\ E(X_1 X_2) &= \frac{2}{8} + 1 \cdot 2 \cdot \frac{2}{8} + 2 \cdot 2 \cdot \frac{1}{8} + 2 \cdot 3 \cdot \frac{1}{8} = 2 \Rightarrow \text{cov}(X_1, X_2) = 2 - 1 \cdot \frac{3}{2} = \frac{1}{2}\end{aligned}$$

From which it follows that $\rho = (1/2)/(\sqrt{(1/2)}\sqrt{3/4}) = 0.816$. ■

Example 2.5.2. Let the random variables X and Y have the joint pdf

$$f(x, y) = \begin{cases} x + y & 0 < x < 1, \quad 0 < y < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

We next compute the correlation coefficient ρ of X and Y . Now

$$\mu_1 = E(X) = \int_0^1 \int_0^1 x(x + y) dx dy = \frac{7}{12}$$

and

$$\sigma_1^2 = E(X^2) - \mu_1^2 = \int_0^1 \int_0^1 x^2(x+y) dx dy - \left(\frac{7}{12}\right)^2 = \frac{11}{144}.$$

Similarly,

$$\mu_2 = E(Y) = \frac{7}{12} \quad \text{and} \quad \sigma_2^2 = E(Y^2) - \mu_2^2 = \frac{11}{144}.$$

The covariance of X and Y is

$$E(XY) - \mu_1\mu_2 = \int_0^1 \int_0^1 xy(x+y) dx dy - \left(\frac{7}{12}\right)^2 = -\frac{1}{144}.$$

Accordingly, the correlation coefficient of X and Y is

$$\rho = \frac{-\frac{1}{144}}{\sqrt{\left(\frac{11}{144}\right)\left(\frac{11}{144}\right)}} = -\frac{1}{11}. \blacksquare$$

We next establish that, in general, $|\rho| \leq 1$.

Theorem 2.5.1. *For all jointly distributed random variables (X, Y) whose correlation coefficient ρ exists, $-1 \leq \rho \leq 1$.*

Proof: Consider the polynomial in v given by

$$h(v) = E \left\{ [(X - \mu_1) + v(Y - \mu_2)]^2 \right\}.$$

Then $h(v) \geq 0$, for all v . Hence, the discriminant of $h(v)$ is less than or equal to 0. To obtain the discriminant, we expand $h(v)$ as

$$h(v) = \sigma_1^2 + 2v\rho\sigma_1\sigma_2 + v^2\sigma_2^2.$$

Hence, the discriminant of $h(v)$ is $4\rho^2\sigma_1^2\sigma_2^2 - 4\sigma_2^2\sigma_1^2$. Since this is less than or equal to 0, we have

$$4\rho^2\sigma_1^2\sigma_2^2 \leq 4\sigma_2^2\sigma_1^2 \quad \text{or} \quad \rho^2 \leq 1,$$

which is the result sought. ■

Theorem 2.5.2. *If X and Y are independent random variables then $\text{cov}(X, Y) = 0$ and, hence, $\rho = 0$.*

Proof: Because X and Y are independent, it follows from expression (2.4.3) that $E(XY) = E(X)E(Y)$. Hence, by (2.5.2) the covariance of X and Y is 0; i.e., $\rho = 0$. ■

As the following example shows, the converse of this theorem is not true:

Example 2.5.3. Let X and Y be jointly discrete random variables whose distribution has mass $1/4$ at each of the four points $(-1, 0), (0, -1), (1, 0)$ and $(0, 1)$. It follows that both X and Y have the same marginal distribution with range $\{-1, 0, 1\}$ and respective probabilities $1/4, 1/2$, and $1/4$. Hence, $\mu_1 = \mu_2 = 0$ and a quick calculation shows that $E(XY) = 0$. Thus, $\rho = 0$. However, $P(X = 0, Y = 0) = 0$ while $P(X = 0)P(Y = 0) = (1/2)(1/2) = 1/4$. Thus, X and Y are dependent but the correlation coefficient of X and Y is 0. ■

Although the converse of Theorem 2.5.2 is not true, the contrapositive is; i.e., if $\rho \neq 0$ then X and Y are dependent. For instance, in Example 2.5.1, since $\rho = 0.816$, we know that the random variables X_1 and X_2 discussed in this example are dependent. As discussed in Section 10.8, this contrapositive is often used in Statistics.

Exercise 2.5.7 points out that in the proof of Theorem 2.5.1, the discriminant of the polynomial $h(v)$ is 0 if and only if $\rho = \pm 1$. In that case X and Y are linear functions of one another with probability one; although, as shown, the relationship is degenerate. This suggests the following interesting question: When ρ does not have one of its extreme values, is there a line in the xy -plane such that the probability for X and Y tends to be concentrated in a band about this line? Under certain restrictive conditions this is, in fact, the case, and under those conditions we can look upon ρ as a measure of the intensity of the concentration of the probability for X and Y about that line.

We summarize these thoughts in the next theorem. For notation, let $f(x, y)$ denote the joint pdf of two random variables X and Y and let $f_1(x)$ denote the marginal pdf of X . Recall from Section 2.3 that the conditional pdf of Y , given $X = x$, is

$$f_{2|1}(y|x) = \frac{f(x, y)}{f_1(x)}$$

at points where $f_1(x) > 0$, and the conditional mean of Y , given $X = x$, is given by

$$E(Y|x) = \int_{-\infty}^{\infty} y f_{2|1}(y|x) dy = \frac{\int_{-\infty}^{\infty} y f(x, y) dy}{f_1(x)},$$

when dealing with random variables of the continuous type. This conditional mean of Y , given $X = x$, is, of course, a function of x , say $u(x)$. In a like vein, the conditional mean of X , given $Y = y$, is a function of y , say $v(y)$.

In case $u(x)$ is a linear function of x , say $u(x) = a + bx$, we say the conditional mean of Y is linear in x ; or that Y has a linear conditional mean. When $u(x) = a + bx$, the constants a and b have simple values which we show in the following theorem.

Theorem 2.5.3. *Suppose (X, Y) have a joint distribution with the variances of X and Y finite and positive. Denote the means and variances of X and Y by μ_1, μ_2 and σ_1^2, σ_2^2 , respectively, and let ρ be the correlation coefficient between X and Y . If $E(Y|X)$ is linear in X then*

$$E(Y|X) = \mu_2 + \rho \frac{\sigma_2}{\sigma_1} (X - \mu_1) \tag{2.5.4}$$

and

$$E(Var(Y|X)) = \sigma_2^2(1 - \rho^2). \tag{2.5.5}$$

Proof: The proof is given in the continuous case. The discrete case follows similarly.

by changing integrals to sums. Let $E(Y|x) = a + bx$. From

$$E(Y|x) = \frac{\int_{-\infty}^{\infty} y f(x,y) dy}{f_1(x)} = a + bx,$$

we have

$$\int_{-\infty}^{\infty} y f(x,y) dy = (a + bx)f_1(x). \quad (2.5.6)$$

If both members of Equation (2.5.6) are integrated on x , it is seen that

$$E(Y) = a + bE(X)$$

or

$$\mu_2 = a + b\mu_1, \quad (2.5.7)$$

where $\mu_1 = E(X)$ and $\mu_2 = E(Y)$. If both members of Equation (2.5.6) are first multiplied by x and then integrated on x , we have

$$E(XY) = aE(X) + bE(X^2),$$

or

$$\rho\sigma_1\sigma_2 + \mu_1\mu_2 = a\mu_1 + b(\sigma_1^2 + \mu_1^2), \quad (2.5.8)$$

where $\rho\sigma_1\sigma_2$ is the covariance of X and Y . The simultaneous solution of equations (2.5.7) and (2.5.8) yields

$$a = \mu_2 - \rho \frac{\sigma_2}{\sigma_1} \mu_1 \quad \text{and} \quad b = \rho \frac{\sigma_2}{\sigma_1}.$$

These values give the first result (2.5.4).

Next, the conditional variance of Y is given by

$$\begin{aligned} \text{Var}(Y|x) &= \int_{-\infty}^{\infty} \left[y - \mu_2 - \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1) \right]^2 f_{2|1}(y|x) dy \\ &= \frac{\int_{-\infty}^{\infty} \left[(y - \mu_2) - \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1) \right]^2 f(x,y) dy}{f_1(x)}. \end{aligned} \quad (2.5.9)$$

This variance is nonnegative and is at most a function of x alone. If it is multiplied by $f_1(x)$ and integrated on x , the result obtained is nonnegative. This result is

$$\begin{aligned} &\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left[(y - \mu_2) - \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1) \right]^2 f(x,y) dy dx \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left[(y - \mu_2)^2 - 2\rho \frac{\sigma_2}{\sigma_1} (y - \mu_2)(x - \mu_1) + \rho^2 \frac{\sigma_2^2}{\sigma_1^2} (x - \mu_1)^2 \right] f(x,y) dy dx \\ &= E[(Y - \mu_2)^2] - 2\rho \frac{\sigma_2}{\sigma_1} E[(X - \mu_1)(Y - \mu_2)] + \rho^2 \frac{\sigma_2^2}{\sigma_1^2} E[(X - \mu_1)^2] \\ &= \sigma_2^2 - 2\rho \frac{\sigma_2}{\sigma_1} \rho \sigma_1 \sigma_2 + \rho^2 \frac{\sigma_2^2}{\sigma_1^2} \sigma_1^2 \\ &= \sigma_2^2 - 2\rho^2 \sigma_2^2 + \rho^2 \sigma_2^2 = \sigma_2^2(1 - \rho^2), \end{aligned}$$

which is the desired result. ■

Note that if the variance, Equation (2.5.9), is denoted by $k(x)$, then $E[k(X)] = \sigma_2^2(1 - \rho^2) \geq 0$. Accordingly, $\rho^2 \leq 1$, or $-1 \leq \rho \leq 1$. This verifies Theorem 2.5.1 for the special case of linear conditional means.

As a corollary to Theorem 2.5.3, suppose that the variance, Equation (2.5.9), is positive but not a function of x ; that is, the variance is a constant $k > 0$. Now if k is multiplied by $f_1(x)$ and integrated on x , the result is k , so that $k = \sigma_2^2(1 - \rho^2)$. Thus, in this case, the variance of each conditional distribution of Y , given $X = x$, is $\sigma_2^2(1 - \rho^2)$. If $\rho = 0$, the variance of each conditional distribution of Y , given $X = x$, is σ_2^2 , the variance of the marginal distribution of Y . On the other hand, if ρ^2 is near 1, the variance of each conditional distribution of Y , given $X = x$, is relatively small, and there is a high concentration of the probability for this conditional distribution near the mean $E(Y|x) = \mu_2 + \rho(\sigma_2/\sigma_1)(x - \mu_1)$. Similar comments can be made about $E(X|y)$ if it is linear. In particular, $E(X|y) = \mu_1 + \rho(\sigma_1/\sigma_2)(y - \mu_2)$ and $E[\text{Var}(X|Y)] = \sigma_1^2(1 - \rho^2)$.

Example 2.5.4. Let the random variables X and Y have the linear conditional means $E(Y|x) = 4x + 3$ and $E(X|y) = \frac{1}{16}y - 3$. In accordance with the general formulas for the linear conditional means, we see that $E(Y|x) = \mu_2$ if $x = \mu_1$ and $E(X|y) = \mu_1$ if $y = \mu_2$. Accordingly, in this special case, we have $\mu_2 = 4\mu_1 + 3$ and $\mu_1 = \frac{1}{16}\mu_2 - 3$ so that $\mu_1 = -\frac{15}{4}$ and $\mu_2 = -12$. The general formulas for the linear conditional means also show that the product of the coefficients of x and y , respectively, is equal to ρ^2 and that the quotient of these coefficients is equal to σ_2^2/σ_1^2 . Here $\rho^2 = 4(\frac{1}{16}) = \frac{1}{4}$ with $\rho = \frac{1}{2}$ (not $-\frac{1}{2}$), and $\sigma_2^2/\sigma_1^2 = 64$. Thus, from the two linear conditional means, we are able to find the values of μ_1 , μ_2 , ρ , and σ_2/σ_1 , but not the values of σ_1 and σ_2 . ■

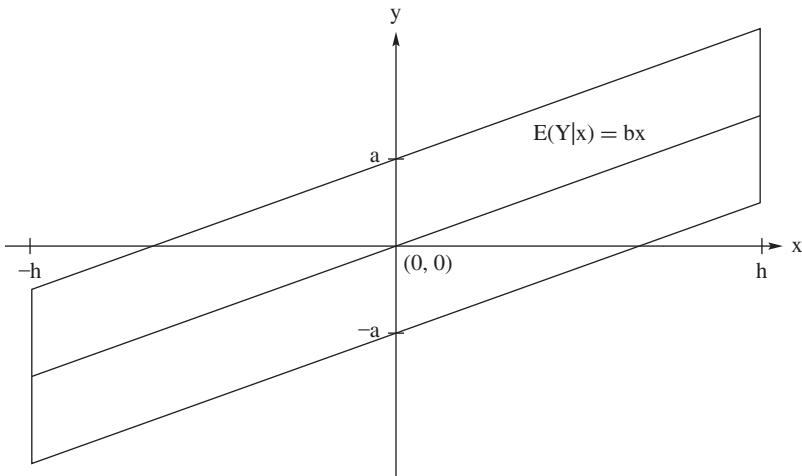

Figure 2.5.1: Illustration for Example 2.5.5.

Example 2.5.5. To illustrate how the correlation coefficient measures the intensity of the concentration of the probability for X and Y about a line, let these random variables have a distribution that is uniform over the area depicted in Figure 2.5.1. That is, the joint pdf of X and Y is

$$f(x, y) = \begin{cases} \frac{1}{4ah} & -a + bx < y < a + bx, \quad -h < x < h \\ 0 & \text{elsewhere.} \end{cases}$$

We assume here that $b \geq 0$, but the argument can be modified for $b \leq 0$. It is easy to show that the pdf of X is uniform, namely

$$f_1(x) = \begin{cases} \int_{-a+bx}^{a+bx} \frac{1}{4ah} dy = \frac{1}{2h} & -h < x < h \\ 0 & \text{elsewhere.} \end{cases}$$

The conditional mean and variance are

$$E(Y|x) = bx \quad \text{and} \quad \text{var}(Y|x) = \frac{a^2}{3}.$$

From the general expressions for those characteristics we know that

$$b = \rho \frac{\sigma_2}{\sigma_1} \quad \text{and} \quad \frac{a^2}{3} = \sigma_2^2(1 - \rho^2).$$

Additionally, we know that $\sigma_1^2 = h^2/3$. If we solve these three equations, we obtain an expression for the correlation coefficient, namely

$$\rho = \frac{bh}{\sqrt{a^2 + b^2h^2}}.$$

Referring to Figure 2.5.1, we note

1. As a gets small (large), the straight-line effect is more (less) intense and ρ is closer to 1 (0).
2. As h gets large (small), the straight-line effect is more (less) intense and ρ is closer to 1 (0).
3. As b gets large (small), the straight-line effect is more (less) intense and ρ is closer to 1 (0). ■

Recall that in Section 2.1 we introduced the mgf for the random vector (X, Y) . As for random variables, the joint mgf also gives explicit formulas for certain moments. In the case of random variables of the continuous type,

$$\frac{\partial^{k+m} M(t_1, t_2)}{\partial t_1^k \partial t_2^m} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^k y^m e^{t_1 x + t_2 y} f(x, y) dx dy,$$

so that

$$\left. \frac{\partial^{k+m} M(t_1, t_2)}{\partial t_1^k \partial t_2^m} \right|_{t_1=t_2=0} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^k y^m f(x, y) dx dy = E(X^k Y^m).$$

For instance, in a simplified notation that appears to be clear,

$$\begin{aligned}
 \mu_1 &= E(X) = \frac{\partial M(0, 0)}{\partial t_1} \\
 \mu_2 &= E(Y) = \frac{\partial M(0, 0)}{\partial t_2} \\
 \sigma_1^2 &= E(X^2) - \mu_1^2 = \frac{\partial^2 M(0, 0)}{\partial t_1^2} - \mu_1^2 \\
 \sigma_2^2 &= E(Y^2) - \mu_2^2 = \frac{\partial^2 M(0, 0)}{\partial t_2^2} - \mu_2^2 \\
 E[(X - \mu_1)(Y - \mu_2)] &= \frac{\partial^2 M(0, 0)}{\partial t_1 \partial t_2} - \mu_1 \mu_2,
 \end{aligned} \tag{2.5.10}$$

and from these we can compute the correlation coefficient ρ .

It is fairly obvious that the results of equations (2.5.10) hold if X and Y are random variables of the discrete type. Thus the correlation coefficients may be computed by using the mgf of the joint distribution if that function is readily available. An illustrative example follows.

Example 2.5.6 (Example 2.1.10, Continued). In Example 2.1.10, we considered the joint density

$$f(x, y) = \begin{cases} e^{-y} & 0 < x < y < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

and showed that the mgf was

$$M(t_1, t_2) = \frac{1}{(1 - t_1 - t_2)(1 - t_2)},$$

for $t_1 + t_2 < 1$ and $t_2 < 1$. For this distribution, equations (2.5.10) become

$$\begin{aligned}
 \mu_1 &= 1, & \mu_2 &= 2 \\
 \sigma_1^2 &= 1, & \sigma_2^2 &= 2 \\
 E[(X - \mu_1)(Y - \mu_2)] &= 1.
 \end{aligned} \tag{2.5.11}$$

Verification of (2.5.11) is left as an exercise; see Exercise 2.5.5. If, momentarily, we accept these results, the correlation coefficient of X and Y is $\rho = 1/\sqrt{2}$. ■

EXERCISES

2.5.1. Let the random variables X and Y have the joint pmf

- (a) $p(x, y) = \frac{1}{3}$, $(x, y) = (0, 0), (1, 1), (2, 2)$, zero elsewhere.
- (b) $p(x, y) = \frac{1}{3}$, $(x, y) = (0, 2), (1, 1), (2, 0)$, zero elsewhere.
- (c) $p(x, y) = \frac{1}{3}$, $(x, y) = (0, 0), (1, 1), (2, 0)$, zero elsewhere.

In each case compute the correlation coefficient of X and Y .

2.5.2. Let X and Y have the joint pmf described as follows:

(x, y)	(1, 1)	(1, 2)	(1, 3)	(2, 1)	(2, 2)	(2, 3)
$p(x, y)$	$\frac{2}{15}$	$\frac{4}{15}$	$\frac{3}{15}$	$\frac{1}{15}$	$\frac{1}{15}$	$\frac{4}{15}$

and $p(x, y)$ is equal to zero elsewhere.

- (a) Find the means μ_1 and μ_2 , the variances σ_1^2 and σ_2^2 , and the correlation coefficient ρ .
- (b) Compute $E(Y|X = 1)$, $E(Y|X = 2)$, and the line $\mu_2 + \rho(\sigma_2/\sigma_1)(x - \mu_1)$. Do the points $[k, E(Y|X = k)]$, $k = 1, 2$, lie on this line?

2.5.3. Let $f(x, y) = 2$, $0 < x < y$, $0 < y < 1$, zero elsewhere, be the joint pdf of X and Y . Show that the conditional means are, respectively, $(1+x)/2$, $0 < x < 1$, and $y/2$, $0 < y < 1$. Show that the correlation coefficient of X and Y is $\rho = \frac{1}{2}$.

2.5.4. Show that the variance of the conditional distribution of Y , given $X = x$, in Exercise 2.5.3, is $(1-x)^2/12$, $0 < x < 1$, and that the variance of the conditional distribution of X , given $Y = y$, is $y^2/12$, $0 < y < 1$.

2.5.5. Verify the results of equations (2.5.11) of this section.

2.5.6. Let X and Y have the joint pdf $f(x, y) = 1$, $-x < y < x$, $0 < x < 1$, zero elsewhere. Show that, on the set of positive probability density, the graph of $E(Y|x)$ is a straight line, whereas that of $E(X|y)$ is not a straight line.

2.5.7. In the proof of Theorem 2.5.1, consider the case when the discriminant of the polynomial $h(v)$ is 0. Show that this is equivalent to $\rho = \pm 1$. Consider the case when $\rho = 1$. Find the unique root of $h(v)$ and then use the fact that $h(v)$ is 0 at this root to show that Y is a linear function of X with probability 1.

2.5.8. Let $\psi(t_1, t_2) = \log M(t_1, t_2)$, where $M(t_1, t_2)$ is the mgf of X and Y . Show that

$$\frac{\partial \psi(0, 0)}{\partial t_i}, \quad \frac{\partial^2 \psi(0, 0)}{\partial t_i^2}, \quad i = 1, 2,$$

and

$$\frac{\partial^2 \psi(0, 0)}{\partial t_1 \partial t_2}$$

yield the means, the variances, and the covariance of the two random variables. Use this result to find the means, the variances, and the covariance of X and Y of Example 2.5.6.

2.5.9. Let X and Y have the joint pmf $p(x, y) = \frac{1}{7}$, $(0, 0), (1, 0), (0, 1), (1, 1), (2, 1), (1, 2), (2, 2)$, zero elsewhere. Find the correlation coefficient ρ .

2.5.10. Let X_1 and X_2 have the joint pmf described by the following table:

(x_1, x_2)	$(0, 0)$	$(0, 1)$	$(0, 2)$	$(1, 1)$	$(1, 2)$	$(2, 2)$
$p(x_1, x_2)$	$\frac{1}{12}$	$\frac{2}{12}$	$\frac{1}{12}$	$\frac{3}{12}$	$\frac{4}{12}$	$\frac{1}{12}$

Find $p_1(x_1), p_2(x_2), \mu_1, \mu_2, \sigma_1^2, \sigma_2^2$, and ρ .

2.5.11. Let $\sigma_1^2 = \sigma_2^2 = \sigma^2$ be the common variance of X_1 and X_2 and let ρ be the correlation coefficient of X_1 and X_2 . Show for $k > 0$ that

$$P[|(X_1 - \mu_1) + (X_2 - \mu_2)| \geq k\sigma] \leq \frac{2(1 + \rho)}{k^2}.$$

2.6 Extension to Several Random Variables

The notions about two random variables can be extended immediately to n random variables. We make the following definition of the space of n random variables.

Definition 2.6.1. Consider a random experiment with the sample space \mathcal{C} . Let the random variable X_i assign to each element $c \in \mathcal{C}$ one and only one real number $X_i(c) = x_i$, $i = 1, 2, \dots, n$. We say that (X_1, \dots, X_n) is an n -dimensional **random vector**. The **space** of this random vector is the set of ordered n -tuples $\mathcal{D} = \{(x_1, x_2, \dots, x_n) : x_1 = X_1(c), \dots, x_n = X_n(c), c \in \mathcal{C}\}$. Furthermore, let A be a subset of the space \mathcal{D} . Then $P[(X_1, \dots, X_n) \in A] = P(C)$, where $C = \{c : c \in \mathcal{C} \text{ and } (X_1(c), X_2(c), \dots, X_n(c)) \in A\}$.

In this section, we often use vector notation. We denote $(X_1, \dots, X_n)'$ by the n -dimensional column vector \mathbf{X} and the observed values $(x_1, \dots, x_n)'$ of the random variables by \mathbf{x} . The joint cdf is defined to be

$$F_{\mathbf{X}}(\mathbf{x}) = P[X_1 \leq x_1, \dots, X_n \leq x_n]. \quad (2.6.1)$$

We say that the n random variables X_1, X_2, \dots, X_n are of the discrete type or of the continuous type and have a distribution of that type according to whether the joint cdf can be expressed as

$$F_{\mathbf{X}}(\mathbf{x}) = \sum_{w_1 \leq x_1, \dots, w_n \leq x_n} p(w_1, \dots, w_n),$$

or as

$$F_{\mathbf{X}}(\mathbf{x}) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \cdots \int_{-\infty}^{x_n} f(w_1, \dots, w_n) dw_n \cdots dw_1.$$

For the continuous case,

$$\frac{\partial^n}{\partial x_1 \cdots \partial x_n} F_{\mathbf{X}}(\mathbf{x}) = f(\mathbf{x}), \quad (2.6.2)$$

except possibly on points that have probability zero.

In accordance with the convention of extending the definition of a joint pdf, it is seen that a continuous function f essentially satisfies the conditions of being a pdf if (a) f is defined and is nonnegative for all real values of its argument(s)

and (b) its integral over all real values of its argument(s) is 1. Likewise, a point function p essentially satisfies the conditions of being a joint pmf if (a) p is defined and is nonnegative for all real values of its argument(s) and (b) its sum over all real values of its argument(s) is 1. As in previous sections, it is sometimes convenient to speak of the support set of a random vector. For the discrete case, this would be all points in \mathcal{D} that have positive mass, while for the continuous case these would be all points in \mathcal{D} that can be embedded in an open set of positive probability. We use \mathcal{S} to denote support sets.

Example 2.6.1. Let

$$f(x, y, z) = \begin{cases} e^{-(x+y+z)} & 0 < x, y, z < \infty \\ 0 & \text{elsewhere} \end{cases}$$

be the pdf of the random variables X , Y , and Z . Then the distribution function of X , Y , and Z is given by

$$\begin{aligned} F(x, y, z) &= P(X \leq x, Y \leq y, Z \leq z) \\ &= \int_0^z \int_0^y \int_0^x e^{-u-v-w} du dv dw \\ &= (1 - e^{-x})(1 - e^{-y})(1 - e^{-z}), \quad 0 \leq x, y, z < \infty, \end{aligned}$$

and is equal to zero elsewhere. The relationship (2.6.2) can easily be verified. ■

Let (X_1, X_2, \dots, X_n) be a random vector and let $Y = u(X_1, X_2, \dots, X_n)$ for some function u . As in the bivariate case, the expected value of the random variable exists if the n -fold integral

$$\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} |u(x_1, x_2, \dots, x_n)| f(x_1, x_2, \dots, x_n) dx_1 dx_2 \cdots dx_n$$

exists when the random variables are of the continuous type, or if the n -fold sum

$$\sum_{x_n} \cdots \sum_{x_1} |u(x_1, x_2, \dots, x_n)| p(x_1, x_2, \dots, x_n)$$

exists when the random variables are of the discrete type. If the expected value of Y exists, then its expectation is given by

$$E(Y) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} u(x_1, x_2, \dots, x_n) f(x_1, x_2, \dots, x_n) dx_1 dx_2 \cdots dx_n \quad (2.6.3)$$

for the continuous case, and by

$$E(Y) = \sum_{x_n} \cdots \sum_{x_1} u(x_1, x_2, \dots, x_n) p(x_1, x_2, \dots, x_n) \quad (2.6.4)$$

for the discrete case. The properties of expectation discussed in Section 2.1 hold for the n -dimensional case also. In particular, E is a linear operator. That is, if

$Y_j = u_j(X_1, \dots, X_n)$ for $j = 1, \dots, m$ and each $E(Y_i)$ exists, then

$$E \left[\sum_{j=1}^m k_j Y_j \right] = \sum_{j=1}^m k_j E[Y_j], \quad (2.6.5)$$

where k_1, \dots, k_m are constants.

We next discuss the notions of marginal and conditional probability density functions from the point of view of n random variables. All of the preceding definitions can be directly generalized to the case of n variables in the following manner. Let the random variables X_1, X_2, \dots, X_n be of the continuous type with the joint pdf $f(x_1, x_2, \dots, x_n)$. By an argument similar to the two-variable case, we have for every b ,

$$F_{X_1}(b) = P(X_1 \leq b) = \int_{-\infty}^b f_1(x_1) dx_1,$$

where $f_1(x_1)$ is defined by the $(n - 1)$ -fold integral

$$f_1(x_1) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} f(x_1, x_2, \dots, x_n) dx_2 \cdots dx_n.$$

Therefore, $f_1(x_1)$ is the pdf of the random variable X_1 and $f_1(x_1)$ is called the marginal pdf of X_1 . The marginal probability density functions $f_2(x_2), \dots, f_n(x_n)$ of X_2, \dots, X_n , respectively, are similar $(n - 1)$ -fold integrals.

Up to this point, each marginal pdf has been a pdf of one random variable. It is convenient to extend this terminology to joint probability density functions, which we do now. Let $f(x_1, x_2, \dots, x_n)$ be the joint pdf of the n random variables X_1, X_2, \dots, X_n , just as before. Now, however, take any group of $k < n$ of these random variables and find the joint pdf of them. This joint pdf is called the marginal pdf of this particular group of k variables. To fix the ideas, take $n = 6$, $k = 3$, and let us select the group X_2, X_4, X_5 . Then the marginal pdf of X_2, X_4, X_5 is the joint pdf of this particular group of three variables, namely,

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x_1, x_2, x_3, x_4, x_5, x_6) dx_1 dx_3 dx_6,$$

if the random variables are of the continuous type.

Next we extend the definition of a conditional pdf. Suppose $f_1(x_1) > 0$. Then we define the symbol $f_{2,\dots,n|1}(x_2, \dots, x_n|x_1)$ by the relation

$$f_{2,\dots,n|1}(x_2, \dots, x_n|x_1) = \frac{f(x_1, x_2, \dots, x_n)}{f_1(x_1)},$$

and $f_{2,\dots,n|1}(x_2, \dots, x_n|x_1)$ is called the **joint conditional pdf** of X_2, \dots, X_n , given $X_1 = x_1$. The joint conditional pdf of any $n - 1$ random variables, say $X_1, \dots, X_{i-1}, X_{i+1}, \dots, X_n$, given $X_i = x_i$, is defined as the joint pdf of X_1, \dots, X_n divided by the marginal pdf $f_i(x_i)$, provided that $f_i(x_i) > 0$. More generally, the joint conditional pdf of $n - k$ of the random variables, for given values of the remaining k variables, is defined as the joint pdf of the n variables divided by the marginal

pdf of the particular group of k variables, provided that the latter pdf is positive. We remark that there are many other conditional probability density functions; for instance, see Exercise 2.3.12.

Because a conditional pdf is the pdf of a certain number of random variables, the expectation of a function of these random variables has been defined. To emphasize the fact that a conditional pdf is under consideration, such expectations are called conditional expectations. For instance, the conditional expectation of $u(X_2, \dots, X_n)$, given $X_1 = x_1$, is, for random variables of the continuous type, given by

$$E[u(X_2, \dots, X_n)|x_1] = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} u(x_2, \dots, x_n) f_{2,\dots,n|1}(x_2, \dots, x_n|x_1) dx_2 \cdots dx_n$$

provided $f_1(x_1) > 0$ and the integral converges (absolutely). A useful random variable is given by $h(X_1) = E[u(X_2, \dots, X_n)|X_1]$.

The above discussion of marginal and conditional distributions generalizes to random variables of the discrete type by using pmfs and summations instead of integrals.

Let the random variables X_1, X_2, \dots, X_n have the joint pdf $f(x_1, x_2, \dots, x_n)$ and the marginal probability density functions $f_1(x_1), f_2(x_2), \dots, f_n(x_n)$, respectively. The definition of the independence of X_1 and X_2 is generalized to the mutual independence of X_1, X_2, \dots, X_n as follows: The random variables X_1, X_2, \dots, X_n are said to be **mutually independent** if and only if

$$f(x_1, x_2, \dots, x_n) \equiv f_1(x_1)f_2(x_2) \cdots f_n(x_n),$$

for the continuous case. In the discrete case, X_1, X_2, \dots, X_n are said to be **mutually independent** if and only if

$$p(x_1, x_2, \dots, x_n) \equiv p_1(x_1)p_2(x_2) \cdots p_n(x_n).$$

Suppose X_1, X_2, \dots, X_n are mutually independent. Then

$$\begin{aligned} P(a_1 < X_1 < b_1, a_2 < X_2 < b_2, \dots, a_n < X_n < b_n) \\ &= P(a_1 < X_1 < b_1)P(a_2 < X_2 < b_2) \cdots P(a_n < X_n < b_n) \\ &= \prod_{i=1}^n P(a_i < X_i < b_i), \end{aligned}$$

where the symbol $\prod_{i=1}^n \varphi(i)$ is defined to be

$$\prod_{i=1}^n \varphi(i) = \varphi(1)\varphi(2) \cdots \varphi(n).$$

The theorem that

$$E[u(X_1)v(X_2)] = E[u(X_1)]E[v(X_2)]$$

for independent random variables X_1 and X_2 becomes, for mutually independent random variables X_1, X_2, \dots, X_n ,

$$E[u_1(X_1)u_2(X_2)\cdots u_n(X_n)] = E[u_1(X_1)]E[u_2(X_2)]\cdots E[u_n(X_n)],$$

or

$$E\left[\prod_{i=1}^n u_i(X_i)\right] = \prod_{i=1}^n E[u_i(X_i)].$$

The moment-generating function (mgf) of the joint distribution of n random variables X_1, X_2, \dots, X_n is defined as follows. Suppose that

$$E[\exp(t_1X_1 + t_2X_2 + \cdots + t_nX_n)]$$

exists for $-h_i < t_i < h_i$, $i = 1, 2, \dots, n$, where each h_i is positive. This expectation is denoted by $M(t_1, t_2, \dots, t_n)$ and it is called the mgf of the joint distribution of X_1, \dots, X_n (or simply the mgf of X_1, \dots, X_n). As in the cases of one and two variables, this mgf is unique and uniquely determines the joint distribution of the n variables (and hence all marginal distributions). For example, the mgf of the marginal distributions of X_i is $M(0, \dots, 0, t_i, 0, \dots, 0)$, $i = 1, 2, \dots, n$; that of the marginal distribution of X_i and X_j is $M(0, \dots, 0, t_i, 0, \dots, 0, t_j, 0, \dots, 0)$; and so on. Theorem 2.4.5 of this chapter can be generalized, and the factorization

$$M(t_1, t_2, \dots, t_n) = \prod_{i=1}^n M(0, \dots, 0, t_i, 0, \dots, 0) \quad (2.6.6)$$

is a necessary and sufficient condition for the mutual independence of X_1, X_2, \dots, X_n . Note that we can write the joint mgf in vector notation as

$$M(\mathbf{t}) = E[\exp(\mathbf{t}'\mathbf{X})], \quad \text{for } \mathbf{t} \in B \subset R^n,$$

where $B = \{\mathbf{t} : -h_i < t_i < h_i, i = 1, \dots, n\}$.

The following is a theorem that proves useful in the sequel. It gives the mgf of a linear combination of independent random variables.

Theorem 2.6.1. *Suppose X_1, X_2, \dots, X_n are n mutually independent random variables. Suppose, for all $i = 1, 2, \dots, n$, X_i has mgf $M_i(t)$, for $-h_i < t < h_i$, where $h_i > 0$. Let $T = \sum_{i=1}^n k_i X_i$, where k_1, k_2, \dots, k_n are constants. Then T has the mgf given by*

$$M_T(t) = \prod_{i=1}^n M_i(k_i t), \quad -\min_i\{h_i\} < t < \min_i\{h_i\}. \quad (2.6.7)$$

Proof. Assume t is in the interval $(-\min_i\{h_i\}, \min_i\{h_i\})$. Then, by independence,

$$\begin{aligned} M_T(t) &= E\left[e^{\sum_{i=1}^n t k_i X_i}\right] = E\left[\prod_{i=1}^n e^{(t k_i) X_i}\right] \\ &= \prod_{i=1}^n E\left[e^{t k_i X_i}\right] = \prod_{i=1}^n M_i(k_i t), \end{aligned}$$

which completes the proof. ■

Example 2.6.2. Let X_1, X_2 , and X_3 be three mutually independent random variables and let each have the pdf

$$f(x) = \begin{cases} 2x & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (2.6.8)$$

The joint pdf of X_1, X_2, X_3 is $f(x_1)f(x_2)f(x_3) = 8x_1x_2x_3$, $0 < x_i < 1$, $i = 1, 2, 3$, zero elsewhere. Then, for illustration, the expected value of $5X_1X_2^3 + 3X_2X_3^4$ is

$$\int_0^1 \int_0^1 \int_0^1 (5x_1x_2^3 + 3x_2x_3^4) 8x_1x_2x_3 \, dx_1 dx_2 dx_3 = 2.$$

Let Y be the maximum of X_1, X_2 , and X_3 . Then, for instance, we have

$$\begin{aligned} P(Y \leq \frac{1}{2}) &= P(X_1 \leq \frac{1}{2}, X_2 \leq \frac{1}{2}, X_3 \leq \frac{1}{2}) \\ &= \int_0^{1/2} \int_0^{1/2} \int_0^{1/2} 8x_1x_2x_3 \, dx_1 dx_2 dx_3 \\ &= (\frac{1}{2})^6 = \frac{1}{64}. \end{aligned}$$

In a similar manner, we find that the cdf of Y is

$$G(y) = P(Y \leq y) = \begin{cases} 0 & y < 0 \\ y^6 & 0 \leq y < 1 \\ 1 & 1 \leq y. \end{cases}$$

Accordingly, the pdf of Y is

$$g(y) = \begin{cases} 6y^5 & 0 < y < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad \blacksquare$$

Remark 2.6.1. If X_1, X_2 , and X_3 are mutually independent, they are **pairwise independent** (that is, X_i and X_j , $i \neq j$, where $i, j = 1, 2, 3$, are independent). However, the following example, attributed to S. Bernstein, shows that pairwise independence does not necessarily imply mutual independence. Let X_1, X_2 , and X_3 have the joint pmf

$$p(x_1, x_2, x_3) = \begin{cases} \frac{1}{4} & (x_1, x_2, x_3) \in \{(1, 0, 0), (0, 1, 0), (0, 0, 1), (1, 1, 1)\} \\ 0 & \text{elsewhere.} \end{cases}$$

The joint pmf of X_i and X_j , $i \neq j$, is

$$p_{ij}(x_i, x_j) = \begin{cases} \frac{1}{4} & (x_i, x_j) \in \{(0, 0), (1, 0), (0, 1), (1, 1)\} \\ 0 & \text{elsewhere,} \end{cases}$$

whereas the marginal pmf of X_i is

$$p_i(x_i) = \begin{cases} \frac{1}{2} & x_i = 0, 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Obviously, if $i \neq j$, we have

$$p_{ij}(x_i, x_j) \equiv p_i(x_i)p_j(x_j),$$

and thus X_i and X_j are independent. However,

$$p(x_1, x_2, x_3) \not\equiv p_1(x_1)p_2(x_2)p_3(x_3).$$

Thus X_1, X_2 , and X_3 are not mutually independent.

Unless there is a possible misunderstanding between *mutual* and *pairwise* independence, we usually drop the modifier *mutual*. Accordingly, using this practice in Example 2.6.2, we say that X_1, X_2, X_3 are independent random variables, meaning that they are mutually independent. Occasionally, for emphasis, we use *mutually independent* so that the reader is reminded that this is different from *pairwise independence*.

In addition, if several random variables are mutually independent and have the same distribution, we say that they are **independent and identically distributed**, which we abbreviate as **iid**. So the random variables in Example 2.6.2 are iid with the common pdf given in expression (2.6.8). ■

The following is a useful corollary to Theorem 2.6.1 for iid random variables. Its proof is asked for in Exercise 2.6.7.

Corollary 2.6.1. *Suppose X_1, X_2, \dots, X_n are iid random variables with the common mgf $M(t)$, for $-h < t < h$, where $h > 0$. Let $T = \sum_{i=1}^n X_i$. Then T has the mgf given by*

$$M_T(t) = [M(t)]^n, \quad -h < t < h. \quad (2.6.9)$$

2.6.1 *Multivariate Variance-Covariance Matrix

This section makes explicit use of matrix algebra and it is considered as an optional section.

In Section 2.5 we discussed the covariance between two random variables. In this section we want to extend this discussion to the n -variate case. Let $\mathbf{X} = (X_1, \dots, X_n)'$ be an n -dimensional random vector. Recall that we defined $E(\mathbf{X}) = (E(X_1), \dots, E(X_n))'$, that is, the expectation of a random vector is just the vector of the expectations of its components. Now suppose \mathbf{W} is an $m \times n$ matrix of random variables, say, $\mathbf{W} = [W_{ij}]$ for the random variables W_{ij} , $1 \leq i \leq m$ and $1 \leq j \leq n$. Note that we can always string out the matrix into an $mn \times 1$ random vector. Hence, we define the expectation of a random matrix

$$E[\mathbf{W}] = [E(W_{ij})]. \quad (2.6.10)$$

As the following theorem shows, the linearity of the expectation operator easily follows from this definition:

Theorem 2.6.2. *Let \mathbf{W}_1 and \mathbf{W}_2 be $m \times n$ matrices of random variables, let \mathbf{A}_1 and \mathbf{A}_2 be $k \times m$ matrices of constants, and let \mathbf{B} be an $n \times l$ matrix of constants.*

Then

$$E[\mathbf{A}_1 \mathbf{W}_1 + \mathbf{A}_2 \mathbf{W}_2] = \mathbf{A}_1 E[\mathbf{W}_1] + \mathbf{A}_2 E[\mathbf{W}_2] \quad (2.6.11)$$

$$E[\mathbf{A}_1 \mathbf{W}_1 \mathbf{B}] = \mathbf{A}_1 E[\mathbf{W}_1] \mathbf{B}. \quad (2.6.12)$$

Proof: Because of the linearity of the operator E on random variables, we have for the (i, j) th components of expression (2.6.11) that

$$E \left[\sum_{s=1}^m a_{1is} W_{1sj} + \sum_{s=1}^m a_{2is} W_{2sj} \right] = \sum_{s=1}^m a_{1is} E[W_{1sj}] + \sum_{s=1}^m a_{2is} E[W_{2sj}].$$

Hence by (2.6.10), expression (2.6.11) is true. The derivation of expression (2.6.12) follows in the same manner. ■

Let $\mathbf{X} = (X_1, \dots, X_n)'$ be an n -dimensional random vector, such that $\sigma_i^2 = \text{Var}(X_i) < \infty$. The **mean** of \mathbf{X} is $\boldsymbol{\mu} = E[\mathbf{X}]$ and we define its **variance-covariance matrix** as

$$\text{Cov}(\mathbf{X}) = E[(\mathbf{X} - \boldsymbol{\mu})(\mathbf{X} - \boldsymbol{\mu})'] = [\sigma_{ij}], \quad (2.6.13)$$

where σ_{ii} denotes σ_i^2 . As Exercise 2.6.8 shows, the i th diagonal entry of $\text{Cov}(\mathbf{X})$ is $\sigma_i^2 = \text{Var}(X_i)$ and the (i, j) th off diagonal entry is $\text{Cov}(X_i, X_j)$.

Example 2.6.3 (Example 2.5.6, Continued). In Example 2.5.6, we considered the joint pdf

$$f(x, y) = \begin{cases} e^{-y} & 0 < x < y < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

and showed that the first two moments are

$$\begin{aligned} \mu_1 &= 1, & \mu_2 &= 2 \\ \sigma_1^2 &= 1, & \sigma_2^2 &= 2 \\ E[(X - \mu_1)(Y - \mu_2)] &= 1. \end{aligned} \quad (2.6.14)$$

Let $\mathbf{Z} = (X, Y)'$. Then using the present notation, we have

$$E[\mathbf{Z}] = \begin{bmatrix} 1 \\ 2 \end{bmatrix} \text{ and } \text{Cov}(\mathbf{Z}) = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix}. \blacksquare$$

Two properties of $\text{Cov}(X_i, X_j)$ needed later are summarized in the following theorem:

Theorem 2.6.3. Let $\mathbf{X} = (X_1, \dots, X_n)'$ be an n -dimensional random vector, such that $\sigma_i^2 = \sigma_{ii} = \text{Var}(X_i) < \infty$. Let \mathbf{A} be an $m \times n$ matrix of constants. Then

$$\text{Cov}(\mathbf{X}) = E[\mathbf{X}\mathbf{X}'] - \boldsymbol{\mu}\boldsymbol{\mu}' \quad (2.6.15)$$

$$\text{Cov}(\mathbf{AX}) = \mathbf{A} \text{Cov}(\mathbf{X}) \mathbf{A}'. \quad (2.6.16)$$

Proof: Use Theorem 2.6.2 to derive (2.6.15); i.e.,

$$\begin{aligned}\text{Cov}(\mathbf{X}) &= E[(\mathbf{X} - \boldsymbol{\mu})(\mathbf{X} - \boldsymbol{\mu})'] \\ &= E[\mathbf{X}\mathbf{X}' - \boldsymbol{\mu}\mathbf{X}' - \mathbf{X}\boldsymbol{\mu}' + \boldsymbol{\mu}\boldsymbol{\mu}'] \\ &= E[\mathbf{X}\mathbf{X}'] - \boldsymbol{\mu}E[\mathbf{X}'] - E[\mathbf{X}]\boldsymbol{\mu}' + \boldsymbol{\mu}\boldsymbol{\mu}',\end{aligned}$$

which is the desired result. The proof of (2.6.16) is left as an exercise. ■

All variance-covariance matrices are **positive semi-definite** matrices; that is, $\mathbf{a}'\text{Cov}(\mathbf{X})\mathbf{a} \geq 0$, for all vectors $\mathbf{a} \in R^n$. To see this let \mathbf{X} be a random vector and let \mathbf{a} be any $n \times 1$ vector of constants. Then $Y = \mathbf{a}'\mathbf{X}$ is a random variable and, hence, has nonnegative variance; i.e.,

$$0 \leq \text{Var}(Y) = \text{Var}(\mathbf{a}'\mathbf{X}) = \mathbf{a}'\text{Cov}(\mathbf{X})\mathbf{a}; \quad (2.6.17)$$

hence, $\text{Cov}(\mathbf{X})$ is positive semi-definite.

EXERCISES

2.6.1. Let X, Y, Z have joint pdf $f(x, y, z) = 2(x + y + z)/3$, $0 < x < 1$, $0 < y < 1$, $0 < z < 1$, zero elsewhere.

- (a) Find the marginal probability density functions of X, Y , and Z .
- (b) Compute $P(0 < X < \frac{1}{2}, 0 < Y < \frac{1}{2}, 0 < Z < \frac{1}{2})$ and $P(0 < X < \frac{1}{2}) = P(0 < Y < \frac{1}{2}) = P(0 < Z < \frac{1}{2})$.
- (c) Are X, Y , and Z independent?
- (d) Calculate $E(X^2YZ + 3XY^4Z^2)$.
- (e) Determine the cdf of X, Y , and Z .
- (f) Find the conditional distribution of X and Y , given $Z = z$, and evaluate $E(X + Y|z)$.
- (g) Determine the conditional distribution of X , given $Y = y$ and $Z = z$, and compute $E(X|y, z)$.

2.6.2. Let $f(x_1, x_2, x_3) = \exp[-(x_1 + x_2 + x_3)]$, $0 < x_1 < \infty$, $0 < x_2 < \infty$, $0 < x_3 < \infty$, zero elsewhere, be the joint pdf of X_1, X_2, X_3 .

- (a) Compute $P(X_1 < X_2 < X_3)$ and $P(X_1 = X_2 < X_3)$.
- (b) Determine the joint mgf of X_1, X_2 , and X_3 . Are these random variables independent?

2.6.3. Let X_1, X_2, X_3 , and X_4 be four independent random variables, each with pdf $f(x) = 3(1-x)^2$, $0 < x < 1$, zero elsewhere. If Y is the minimum of these four variables, find the cdf and the pdf of Y .

Hint: $P(Y > y) = P(X_i > y, i = 1, \dots, 4)$.

2.6.4. A fair die is cast at random three independent times. Let the random variable X_i be equal to the number of spots that appear on the i th trial, $i = 1, 2, 3$. Let the random variable Y be equal to $\max(X_i)$. Find the cdf and the pmf of Y .

Hint: $P(Y \leq y) = P(X_i \leq y, i = 1, 2, 3)$.

2.6.5. Let $M(t_1, t_2, t_3)$ be the mgf of the random variables X_1, X_2 , and X_3 of Bernstein's example, described in the remark following Example 2.6.2. Show that

$$M(t_1, t_2, 0) = M(t_1, 0, 0)M(0, t_2, 0), \quad M(t_1, 0, t_3) = M(t_1, 0, 0)M(0, 0, t_3),$$

and

$$M(0, t_2, t_3) = M(0, t_2, 0)M(0, 0, t_3)$$

are true, but that

$$M(t_1, t_2, t_3) \neq M(t_1, 0, 0)M(0, t_2, 0)M(0, 0, t_3).$$

Thus X_1, X_2, X_3 are pairwise independent but not mutually independent.

2.6.6. Let X_1, X_2 , and X_3 be three random variables with means, variances, and correlation coefficients, denoted by $\mu_1, \mu_2, \mu_3; \sigma_1^2, \sigma_2^2, \sigma_3^2$; and $\rho_{12}, \rho_{13}, \rho_{23}$, respectively. For constants b_2 and b_3 , suppose $E(X_1 - \mu_1 | x_2, x_3) = b_2(x_2 - \mu_2) + b_3(x_3 - \mu_3)$. Determine b_2 and b_3 in terms of the variances and the correlation coefficients.

2.6.7. Prove Corollary 2.6.1.

2.6.8. Let $\mathbf{X} = (X_1, \dots, X_n)'$ be an n -dimensional random vector, with the variance-covariance matrix given in display (2.6.13). Show that the i th diagonal entry of $\text{Cov}(\mathbf{X})$ is $\sigma_i^2 = \text{Var}(X_i)$ and that the (i, j) th off diagonal entry is $\text{Cov}(X_i, X_j)$.

2.6.9. Let X_1, X_2, X_3 be iid with common pdf $f(x) = \exp(-x)$, $0 < x < \infty$, zero elsewhere. Evaluate:

- (a) $P(X_1 < X_2 | X_1 < 2X_2)$.
- (b) $P(X_1 < X_2 < X_3 | X_3 < 1)$.

2.7 Transformations for Several Random Variables

In Section 2.2 it was seen that the determination of the joint pdf of two functions of two random variables of the continuous type was essentially a corollary to a theorem in analysis having to do with the change of variables in a twofold integral. This theorem has a natural extension to n -fold integrals. This extension is as follows. Consider an integral of the form

$$\int \cdots \int_A f(x_1, x_2, \dots, x_n) dx_1 dx_2 \cdots dx_n$$

taken over a subset A of an n -dimensional space \mathcal{S} . Let

$$y_1 = u_1(x_1, x_2, \dots, x_n), \quad y_2 = u_2(x_1, x_2, \dots, x_n), \dots, y_n = u_n(x_1, x_2, \dots, x_n),$$

together with the inverse functions

$$x_1 = w_1(y_1, y_2, \dots, y_n), \quad x_2 = w_2(y_1, y_2, \dots, y_n), \dots, x_n = w_n(y_1, y_2, \dots, y_n)$$

define a one-to-one transformation that maps \mathcal{S} onto \mathcal{T} in the y_1, y_2, \dots, y_n space and, hence, maps the subset A of \mathcal{S} onto a subset B of \mathcal{T} . Let the first partial derivatives of the inverse functions be continuous and let the n by n determinant (called the Jacobian)

$$J = \begin{vmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} & \cdots & \frac{\partial x_1}{\partial y_n} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} & \cdots & \frac{\partial x_2}{\partial y_n} \\ \vdots & \vdots & & \vdots \\ \frac{\partial x_n}{\partial y_1} & \frac{\partial x_n}{\partial y_2} & \cdots & \frac{\partial x_n}{\partial y_n} \end{vmatrix}$$

not be identically zero in \mathcal{T} . Then

$$\begin{aligned} & \int \cdots \int_A f(x_1, x_2, \dots, x_n) dx_1 dx_2 \cdots dx_n \\ &= \int \cdots \int_B f[w_1(y_1, \dots, y_n), w_2(y_1, \dots, y_n), \dots, w_n(y_1, \dots, y_n)] |J| dy_1 dy_2 \cdots dy_n. \end{aligned}$$

Whenever the conditions of this theorem are satisfied, we can determine the joint pdf of n functions of n random variables. Appropriate changes of notation in Section 2.2 (to indicate n -space as opposed to 2-space) are all that are needed to show that the joint pdf of the random variables $Y_1 = u_1(X_1, X_2, \dots, X_n), \dots, Y_n = u_n(X_1, X_2, \dots, X_n)$, where the joint pdf of X_1, \dots, X_n is $f(x_1, \dots, x_n)$, is given by

$$g(y_1, y_2, \dots, y_n) = f[w_1(y_1, \dots, y_n), \dots, w_n(y_1, \dots, y_n)] |J|,$$

where $(y_1, y_2, \dots, y_n) \in \mathcal{T}$, and is zero elsewhere.

Example 2.7.1. Let X_1, X_2, X_3 have the joint pdf

$$f(x_1, x_2, x_3) = \begin{cases} 48x_1x_2x_3 & 0 < x_1 < x_2 < x_3 < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (2.7.1)$$

If $Y_1 = X_1/X_2$, $Y_2 = X_2/X_3$, and $Y_3 = X_3$, then the inverse transformation is given by

$$x_1 = y_1 y_2 y_3, \quad x_2 = y_2 y_3, \quad \text{and} \quad x_3 = y_3.$$

The Jacobian is given by

$$J = \begin{vmatrix} y_2 y_3 & y_1 y_3 & y_1 y_2 \\ 0 & y_3 & y_2 \\ 0 & 0 & 1 \end{vmatrix} = y_2 y_3^2.$$

Moreover, inequalities defining the support are equivalent to

$$0 < y_1 y_2 y_3, \quad y_1 y_2 y_3 < y_2 y_3, \quad y_2 y_3 < y_3, \quad \text{and} \quad y_3 < 1,$$

which reduces to the support \mathcal{T} of Y_1, Y_2, Y_3 of

$$\mathcal{T} = \{(y_1, y_2, y_3) : 0 < y_i < 1, i = 1, 2, 3\}.$$

Hence the joint pdf of Y_1, Y_2, Y_3 is

$$\begin{aligned} g(y_1, y_2, y_3) &= 48(y_1 y_2 y_3)(y_2 y_3) y_3 |y_2 y_3^2| \\ &= \begin{cases} 48 y_1 y_2^3 y_3^5 & 0 < y_i < 1, i = 1, 2, 3 \\ 0 & \text{elsewhere.} \end{cases} \end{aligned} \quad (2.7.2)$$

The marginal pdfs are

$$\begin{aligned} g_1(y_1) &= 2y_1, 0 < y_1 < 1, \text{ zero elsewhere} \\ g_2(y_2) &= 4y_2^3, 0 < y_2 < 1, \text{ zero elsewhere} \\ g_3(y_3) &= 6y_3^5, 0 < y_3 < 1, \text{ zero elsewhere.} \end{aligned}$$

Because $g(y_1, y_2, y_3) = g_1(y_1)g_2(y_2)g_3(y_3)$, the random variables Y_1, Y_2, Y_3 are mutually independent. ■

Example 2.7.2. Let X_1, X_2, X_3 be iid with common pdf

$$f(x) = \begin{cases} e^{-x} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Consequently, the joint pdf of X_1, X_2, X_3 is

$$f_{X_1, X_2, X_3}(x_1, x_2, x_3) = \begin{cases} e^{-\sum_{i=1}^3 x_i} & 0 < x_i < \infty, i = 1, 2, 3 \\ 0 & \text{elsewhere.} \end{cases}$$

Consider the random variables Y_1, Y_2, Y_3 defined by

$$Y_1 = \frac{X_1}{X_1 + X_2 + X_3}, \quad Y_2 = \frac{X_2}{X_1 + X_2 + X_3}, \quad \text{and} \quad Y_3 = X_1 + X_2 + X_3.$$

Hence, the inverse transformation is given by

$$x_1 = y_1 y_3, \quad x_2 = y_2 y_3, \quad \text{and} \quad x_3 = y_3 - y_1 y_3 - y_2 y_3,$$

with the Jacobian

$$J = \begin{vmatrix} y_3 & 0 & y_1 \\ 0 & y_3 & y_2 \\ -y_3 & -y_3 & 1 - y_1 - y_2 \end{vmatrix} = y_3^2.$$

The support of X_1, X_2, X_3 maps onto

$$0 < y_1 y_3 < \infty, \quad 0 < y_2 y_3 < \infty, \quad \text{and} \quad 0 < y_3(1 - y_1 - y_2) < \infty,$$

which is equivalent to the support \mathcal{T} given by

$$\mathcal{T} = \{(y_1, y_2, y_3) : 0 < y_1, 0 < y_2, 0 < 1 - y_1 - y_2, 0 < y_3 < \infty\}.$$

Hence the joint pdf of Y_1, Y_2, Y_3 is

$$g(y_1, y_2, y_3) = y_3^2 e^{-y_3}, \quad (y_1, y_2, y_3) \in \mathcal{T}.$$

The marginal pdf of Y_1 is

$$g_1(y_1) = \int_0^{1-y_1} \int_0^\infty y_3^2 e^{-y_3} dy_3 dy_2 = 2(1 - y_1), \quad 0 < y_1 < 1,$$

zero elsewhere. Likewise the marginal pdf of Y_2 is

$$g_2(y_2) = 2(1 - y_2), \quad 0 < y_2 < 1,$$

zero elsewhere, while the pdf of Y_3 is

$$g_3(y_3) = \int_0^1 \int_0^{1-y_1} y_3^2 e^{-y_3} dy_2 dy_1 = \frac{1}{2} y_3^2 e^{-y_3}, \quad 0 < y_3 < \infty,$$

zero elsewhere. Because $g(y_1, y_2, y_3) \neq g_1(y_1)g_2(y_2)g_3(y_3)$, Y_1, Y_2, Y_3 are dependent random variables.

Note, however, that the joint pdf of Y_1 and Y_3 is

$$g_{13}(y_1, y_3) = \int_0^{1-y_1} y_3^2 e^{-y_3} dy_2 = (1 - y_1)y_3^2 e^{-y_3}, \quad 0 < y_1 < 1, 0 < y_3 < \infty,$$

zero elsewhere. Hence Y_1 and Y_3 are independent. In a similar manner, Y_2 and Y_3 are also independent. Because the joint pdf of Y_1 and Y_2 is

$$g_{12}(y_1, y_2) = \int_0^\infty y_3^2 e^{-y_3} dy_3 = 2, \quad 0 < y_1, 0 < y_2, y_1 + y_2 < 1,$$

zero elsewhere, Y_1 and Y_2 are seen to be dependent. ■

We now consider some other problems that are encountered when transforming variables. Let X have the Cauchy pdf

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad -\infty < x < \infty,$$

and let $Y = X^2$. We seek the pdf $g(y)$ of Y . Consider the transformation $y = x^2$. This transformation maps the space of X , namely $\mathcal{S} = \{x : -\infty < x < \infty\}$, onto $\mathcal{T} = \{y : 0 \leq y < \infty\}$. However, the transformation is not one-to-one. To each $y \in \mathcal{T}$, with the exception of $y = 0$, there correspond two points $x \in \mathcal{S}$. For example, if $y = 4$, we may have either $x = 2$ or $x = -2$. In such an instance, we represent \mathcal{S} as the union of two disjoint sets A_1 and A_2 such that $y = x^2$ defines a one-to-one transformation that maps each of A_1 and A_2 onto \mathcal{T} . If we take A_1 to be $\{x : -\infty < x < 0\}$ and A_2 to be $\{x : 0 \leq x < \infty\}$, we see that A_1 is mapped onto $\{y : 0 < y < \infty\}$, whereas A_2 is mapped onto $\{y : 0 \leq y < \infty\}$, and these sets are not the same. Our difficulty is caused by the fact that $x = 0$ is an element of \mathcal{S} . Why, then, do we not return to the Cauchy pdf and take

$f(0) = 0$? Then our new \mathcal{S} is $\mathcal{S} = \{-\infty < x < \infty \text{ but } x \neq 0\}$. We then take $A_1 = \{x : -\infty < x < 0\}$ and $A_2 = \{x : 0 < x < \infty\}$. Thus $y = x^2$, with the inverse $x = -\sqrt{y}$, maps A_1 onto $\mathcal{T} = \{y : 0 < y < \infty\}$ and the transformation is one-to-one. Moreover, the transformation $y = x^2$, with inverse $x = \sqrt{y}$, maps A_2 onto $\mathcal{T} = \{y : 0 < y < \infty\}$ and the transformation is one-to-one. Consider the probability $P(Y \in B)$, where $B \subset \mathcal{T}$. Let $A_3 = \{x : x = -\sqrt{y}, y \in B\} \subset A_1$ and let $A_4 = \{x : x = \sqrt{y}, y \in B\} \subset A_2$. Then $Y \in B$ when and only when $X \in A_3$ or $X \in A_4$. Thus we have

$$\begin{aligned} P(Y \in B) &= P(X \in A_3) + P(X \in A_4) \\ &= \int_{A_3} f(x) dx + \int_{A_4} f(x) dx. \end{aligned}$$

In the first of these integrals, let $x = -\sqrt{y}$. Thus the Jacobian, say J_1 , is $-1/2\sqrt{y}$; furthermore, the set A_3 is mapped onto B . In the second integral let $x = \sqrt{y}$. Thus the Jacobian, say J_2 , is $1/2\sqrt{y}$; furthermore, the set A_4 is also mapped onto B . Finally,

$$\begin{aligned} P(Y \in B) &= \int_B f(-\sqrt{y}) \left| -\frac{1}{2\sqrt{y}} \right| dy + \int_B f(\sqrt{y}) \frac{1}{2\sqrt{y}} dy \\ &= \int_B [f(-\sqrt{y}) + f(\sqrt{y})] \frac{1}{2\sqrt{y}} dy. \end{aligned}$$

Hence the pdf of Y is given by

$$g(y) = \frac{1}{2\sqrt{y}} [f(-\sqrt{y}) + f(\sqrt{y})], \quad y \in \mathcal{T}.$$

With $f(x)$ the Cauchy pdf we have

$$g(y) = \begin{cases} \frac{1}{\pi(1+y)\sqrt{y}} & 0 < y < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

In the preceding discussion of a random variable of the continuous type, we had two inverse functions, $x = -\sqrt{y}$ and $x = \sqrt{y}$. That is why we sought to partition \mathcal{S} (or a modification of \mathcal{S}) into two disjoint subsets such that the transformation $y = x^2$ maps each onto the same \mathcal{T} . Had there been three inverse functions, we would have sought to partition \mathcal{S} (or a modified form of \mathcal{S}) into three disjoint subsets, and so on. It is hoped that this detailed discussion makes the following paragraph easier to read.

Let $f(x_1, x_2, \dots, x_n)$ be the joint pdf of X_1, X_2, \dots, X_n , which are random variables of the continuous type. Let \mathcal{S} denote the n -dimensional space where this joint pdf $f(x_1, x_2, \dots, x_n) > 0$, and consider the transformation $y_1 = u_1(x_1, x_2, \dots, x_n), \dots, y_n = u_n(x_1, x_2, \dots, x_n)$, which maps \mathcal{S} onto \mathcal{T} in the y_1, y_2, \dots, y_n space. To each point of \mathcal{S} there corresponds, of course, only one point in \mathcal{T} ; but to a point in \mathcal{T} there may correspond more than one point in \mathcal{S} . That is, the transformation

may not be one-to-one. Suppose, however, that we can represent \mathcal{S} as the union of a finite number, say k , of mutually disjoint sets A_1, A_2, \dots, A_k so that

$$y_1 = u_1(x_1, x_2, \dots, x_n), \dots, y_n = u_n(x_1, x_2, \dots, x_n)$$

define a one-to-one transformation of each A_i onto \mathcal{T} . Thus to each point in \mathcal{T} there corresponds exactly one point in each of A_1, A_2, \dots, A_k . For $i = 1, \dots, k$, let

$$x_1 = w_{1i}(y_1, y_2, \dots, y_n), x_2 = w_{2i}(y_1, y_2, \dots, y_n), \dots, x_n = w_{ni}(y_1, y_2, \dots, y_n),$$

denote the k groups of n inverse functions, one group for each of these k transformations. Let the first partial derivatives be continuous and let each

$$J_i = \begin{vmatrix} \frac{\partial w_{1i}}{\partial y_1} & \frac{\partial w_{1i}}{\partial y_2} & \cdots & \frac{\partial w_{1i}}{\partial y_n} \\ \frac{\partial w_{2i}}{\partial y_1} & \frac{\partial w_{2i}}{\partial y_2} & \cdots & \frac{\partial w_{2i}}{\partial y_n} \\ \vdots & \vdots & & \vdots \\ \frac{\partial w_{ni}}{\partial y_1} & \frac{\partial w_{ni}}{\partial y_2} & \cdots & \frac{\partial w_{ni}}{\partial y_n} \end{vmatrix}, \quad i = 1, 2, \dots, k,$$

be not identically equal to zero in \mathcal{T} . Considering the probability of the union of k mutually exclusive events and by applying the change-of-variable technique to the probability of each of these events, it can be seen that the joint pdf of $Y_1 = u_1(X_1, X_2, \dots, X_n), Y_2 = u_2(X_1, X_2, \dots, X_n), \dots, Y_n = u_n(X_1, X_2, \dots, X_n)$, is given by

$$g(y_1, y_2, \dots, y_n) = \sum_{i=1}^k f[w_{1i}(y_1, \dots, y_n), \dots, w_{ni}(y_1, \dots, y_n)] |J_i|,$$

provided that $(y_1, y_2, \dots, y_n) \in \mathcal{T}$, and equals zero elsewhere. The pdf of any Y_i , say Y_1 , is then

$$g_1(y_1) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} g(y_1, y_2, \dots, y_n) dy_2 \cdots dy_n.$$

Example 2.7.3. Let X_1 and X_2 have the joint pdf defined over the unit circle given by

$$f(x_1, x_2) = \begin{cases} \frac{1}{\pi} & 0 < x_1^2 + x_2^2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Let $Y_1 = X_1^2 + X_2^2$ and $Y_2 = X_1^2/(X_1^2 + X_2^2)$. Thus $y_1 y_2 = x_1^2$ and $x_2^2 = y_1(1 - y_2)$. The support \mathcal{S} maps onto $\mathcal{T} = \{(y_1, y_2) : 0 < y_i < 1, i = 1, 2\}$. For each ordered pair $(y_1, y_2) \in \mathcal{T}$, there are four points in \mathcal{S} , given by

$$\begin{aligned} (x_1, x_2) &\text{ such that } x_1 = \sqrt{y_1 y_2} \text{ and } x_2 = \sqrt{y_1(1 - y_2)} \\ (x_1, x_2) &\text{ such that } x_1 = \sqrt{y_1 y_2} \text{ and } x_2 = -\sqrt{y_1(1 - y_2)} \\ (x_1, x_2) &\text{ such that } x_1 = -\sqrt{y_1 y_2} \text{ and } x_2 = \sqrt{y_1(1 - y_2)} \\ \text{and } (x_1, x_2) &\text{ such that } x_1 = -\sqrt{y_1 y_2} \text{ and } x_2 = -\sqrt{y_1(1 - y_2)}. \end{aligned}$$

The value of the first Jacobian is

$$\begin{aligned} J_1 &= \begin{vmatrix} \frac{1}{2}\sqrt{y_2/y_1} & \frac{1}{2}\sqrt{y_1/y_2} \\ \frac{1}{2}\sqrt{(1-y_2)/y_1} & -\frac{1}{2}\sqrt{y_1/(1-y_2)} \end{vmatrix} \\ &= \frac{1}{4} \left\{ -\sqrt{\frac{1-y_2}{y_2}} - \sqrt{\frac{y_2}{1-y_2}} \right\} = -\frac{1}{4} \frac{1}{\sqrt{y_2(1-y_2)}}. \end{aligned}$$

It is easy to see that the absolute value of each of the four Jacobians equals $1/4\sqrt{y_2(1-y_2)}$. Hence, the joint pdf of Y_1 and Y_2 is the sum of four terms and can be written as

$$g(y_1, y_2) = 4 \frac{1}{\pi} \frac{1}{4\sqrt{y_2(1-y_2)}} = \frac{1}{\pi\sqrt{y_2(1-y_2)}}, \quad (y_1, y_2) \in \mathcal{T}.$$

Thus Y_1 and Y_2 are independent random variables by Theorem 2.4.1. ■

Of course, as in the bivariate case, we can use the mgf technique by noting that if $Y = g(X_1, X_2, \dots, X_n)$ is a function of the random variables, then the mgf of Y is given by

$$E(e^{tY}) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} e^{tg(x_1, x_2, \dots, x_n)} f(x_1, x_2, \dots, x_n) dx_1 dx_2 \cdots dx_n,$$

in the continuous case, where $f(x_1, x_2, \dots, x_n)$ is the joint pdf. In the discrete case, summations replace the integrals. This procedure is particularly useful in cases in which we are dealing with linear functions of independent random variables.

Example 2.7.4 (Extension of Example 2.2.6). Let X_1, X_2, X_3 be independent random variables with joint pmf

$$p(x_1, x_2, x_3) = \begin{cases} \frac{\mu_1^{x_1} \mu_2^{x_2} \mu_3^{x_3} e^{-\mu_1 - \mu_2 - \mu_3}}{x_1! x_2! x_3!} & x_i = 0, 1, 2, \dots, i = 1, 2, 3 \\ 0 & \text{elsewhere.} \end{cases}$$

If $Y = X_1 + X_2 + X_3$, the mgf of Y is

$$\begin{aligned} E(e^{tY}) &= E(e^{t(X_1 + X_2 + X_3)}) \\ &= E(e^{tX_1} e^{tX_2} e^{tX_3}) \\ &= E(e^{tX_1}) E(e^{tX_2}) E(e^{tX_3}), \end{aligned}$$

because of the independence of X_1, X_2, X_3 . In Example 2.2.6, we found that

$$E(e^{tX_i}) = \exp\{\mu_i(e^t - 1)\}, \quad i = 1, 2, 3.$$

Hence,

$$E(e^{tY}) = \exp\{(\mu_1 + \mu_2 + \mu_3)(e^t - 1)\}.$$

This, however, is the mgf of the pmf

$$p_Y(y) = \begin{cases} \frac{(\mu_1 + \mu_2 + \mu_3)^y e^{-(\mu_1 + \mu_2 + \mu_3)}}{y!} & y = 0, 1, 2, \dots \\ 0 & \text{elsewhere,} \end{cases}$$

so $Y = X_1 + X_2 + X_3$ has this distribution. ■

Example 2.7.5. Let X_1, X_2, X_3, X_4 be independent random variables with common pdf

$$f(x) = \begin{cases} e^{-x} & x > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

If $Y = X_1 + X_2 + X_3 + X_4$, then similar to the argument in the last example, the independence of X_1, X_2, X_3, X_4 implies that

$$E(e^{tY}) = E(e^{tX_1}) E(e^{tX_2}) E(e^{tX_3}) E(e^{tX_4}).$$

In Section 1.9, we saw that

$$E(e^{tX_i}) = (1-t)^{-1}, \quad t < 1, \quad i = 1, 2, 3, 4.$$

Hence,

$$E(e^{tY}) = (1-t)^{-4}.$$

In Section 3.3, we find that this is the mgf of a distribution with pdf

$$f_Y(y) = \begin{cases} \frac{1}{3!} y^3 e^{-y} & 0 < y < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Accordingly, Y has this distribution. ■

EXERCISES

2.7.1. Let X_1, X_2, X_3 be iid, each with the distribution having pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Show that

$$Y_1 = \frac{X_1}{X_1 + X_2}, \quad Y_2 = \frac{X_1 + X_2}{X_1 + X_2 + X_3}, \quad Y_3 = X_1 + X_2 + X_3$$

are mutually independent.

2.7.2. If $f(x) = \frac{1}{2}$, $-1 < x < 1$, zero elsewhere, is the pdf of the random variable X , find the pdf of $Y = X^2$.

2.7.3. If X has the pdf of $f(x) = \frac{1}{4}$, $-1 < x < 3$, zero elsewhere, find the pdf of $Y = X^2$.

Hint: Here $\mathcal{T} = \{y : 0 \leq y < 9\}$ and the event $Y \in B$ is the union of two mutually exclusive events if $B = \{y : 0 < y < 1\}$.

2.7.4. Let X_1, X_2, X_3 be iid with common pdf $f(x) = e^{-x}$, $x > 0$, 0 elsewhere. Find the joint pdf of $Y_1 = X_1$, $Y_2 = X_1 + X_2$, and $Y_3 = X_1 + X_2 + X_3$.

2.7.5. Let X_1, X_2, X_3 be iid with common pdf $f(x) = e^{-x}$, $x > 0$, 0 elsewhere. Find the joint pdf of $Y_1 = X_1/X_2$, $Y_2 = X_3/(X_1 + X_2)$, and $Y_3 = X_1 + X_2$. Are Y_1, Y_2, Y_3 mutually independent?

2.7.6. Let X_1, X_2 have the joint pdf $f(x_1, x_2) = 1/\pi$, $0 < x_1^2 + x_2^2 < 1$. Let $Y_1 = X_1^2 + X_2^2$ and $Y_2 = X_2$. Find the joint pdf of Y_1 and Y_2 .

2.7.7. Let X_1, X_2, X_3, X_4 have the joint pdf $f(x_1, x_2, x_3, x_4) = 24$, $0 < x_1 < x_2 < x_3 < x_4 < 1$, 0 elsewhere. Find the joint pdf of $Y_1 = X_1/X_2$, $Y_2 = X_2/X_3$, $Y_3 = X_3/X_4$, $Y_4 = X_4$ and show that they are mutually independent.

2.7.8. Let X_1, X_2, X_3 be iid with common mgf $M(t) = ((3/4) + (1/4)e^t)^2$, for all $t \in R$.

(a) Determine the probabilities, $P(X_1 = k)$, $k = 0, 1, 2$.

(b) Find the mgf of $Y = X_1 + X_2 + X_3$ and then determine the probabilities, $P(Y = k)$, $k = 0, 1, 2, \dots, 6$.

2.8 Linear Combinations of Random Variables

In this section, we summarize some results on linear combinations of random variables that follow from Section 2.6. These results will prove to be quite useful in Chapter 3 as well as in succeeding chapters.

Let $(X_1, \dots, X_n)'$ denote a random vector. In this section, we consider linear combinations of these variables, writing them , generally, as

$$T = \sum_{i=1}^n a_i X_i, \quad (2.8.1)$$

for specified constants a_1, \dots, a_n . We obtain expressions for the mean and variance of T .

The mean of T follows immediately from linearity of expectation. For reference, we state it formally as a theorem.

Theorem 2.8.1. Suppose T is given by expression (2.8.1). Suppose $E(X_i) = \mu_i$, for $i = 1, \dots, n$. Then

$$E(T) = \sum_{i=1}^n a_i \mu_i. \quad (2.8.2)$$

In order to obtain the variance of T , we first state a general result on covariances.

Theorem 2.8.2. Suppose T is the linear combination (2.8.1) and that W is another linear combination given by $W = \sum_{i=1}^m b_i Y_i$, for random variables Y_1, \dots, Y_m and specified constants b_1, \dots, b_m . Let $T = \sum_{i=1}^n a_i X_i$ and let $W = \sum_{i=1}^m b_i Y_i$. If $E[X_i^2] < \infty$, and $E[Y_j^2] < \infty$ for $i = 1, \dots, n$ and $j = 1, \dots, m$, then

$$\text{Cov}(T, W) = \sum_{i=1}^n \sum_{j=1}^m a_i b_j \text{Cov}(X_i, Y_j). \quad (2.8.3)$$

Proof: Using the definition of the covariance and Theorem 2.8.1, we have the first equality below, while the second equality follows from the linearity of E :

$$\begin{aligned}\text{Cov}(T, W) &= E \left[\sum_{i=1}^n \sum_{j=1}^m (a_i X_i - a_i E(X_i))(b_j Y_j - b_j E(Y_j)) \right] \\ &= \sum_{i=1}^n \sum_{j=1}^m a_i b_j E[(X_i - E(X_i))(Y_j - E(Y_j))],\end{aligned}$$

which is the desired result. ■

To obtain the variance of T , simply replace W by T in expression (2.8.3). We state the result as a corollary:

Corollary 2.8.1. *Let $T = \sum_{i=1}^n a_i X_i$. Provided $E[X_i^2] < \infty$, for $i = 1, \dots, n$,*

$$\text{Var}(T) = \text{Cov}(T, T) = \sum_{i=1}^n a_i^2 \text{Var}(X_i) + 2 \sum_{i < j} a_i a_j \text{Cov}(X_i, X_j). \quad (2.8.4)$$

Note that if X_1, \dots, X_n are independent random variables, then by Theorem 2.5.2 all the pairwise covariances are 0; i.e., $\text{Cov}(X_i, X_j) = 0$ for all $i \neq j$. This leads to a simplification of (2.8.4), which we record in the following corollary.

Corollary 2.8.2. *If X_1, \dots, X_n are independent random variables and $\text{Var}(X_i) = \sigma_i^2$, for $i = 1, \dots, n$, then*

$$\text{Var}(T) = \sum_{i=1}^n a_i^2 \sigma_i^2. \quad (2.8.5)$$

Note that we need only X_i and X_j to be uncorrelated for all $i \neq j$ to obtain this result.

Next, in addition to independence, we assume that the random variables have the same distribution. We call such a collection of random variables a *random sample* which we now state in a formal definition.

Definition 2.8.1. *If the random variables X_1, X_2, \dots, X_n are independent and identically distributed, i.e. each X_i has the same distribution, then we say that these random variables constitute a **random sample** of size n from that common distribution. We abbreviate independent and identically distributed by **iid**.* ■

In the next two examples, we find some properties of two functions of a random sample, namely the sample mean and variance.

Example 2.8.1 (Sample Mean). Let X_1, \dots, X_n be independent and identically distributed random variables with common mean μ and variance σ^2 . The **sample mean** is defined by $\bar{X} = n^{-1} \sum_{i=1}^n X_i$. This is a linear combination of the sample observations with $a_i \equiv n^{-1}$; hence, by Theorem 2.8.1 and Corollary 2.8.2, we have

$$E(\bar{X}) = \mu \text{ and } \text{Var}(\bar{X}) = \frac{\sigma^2}{n}. \quad (2.8.6)$$

Because $E(\bar{X}) = \mu$, we often say that \bar{X} is **unbiased** for μ . ■

Example 2.8.2 (Sample Variance). Define the **sample variance** by

$$S^2 = (n-1)^{-1} \sum_{i=1}^n (X_i - \bar{X})^2 = (n-1)^{-1} \left(\sum_{i=1}^n X_i^2 - n\bar{X}^2 \right), \quad (2.8.7)$$

where the second equality follows after some algebra; see Exercise 2.8.1.

In the average that defines the sample variance S^2 , the division is by $n-1$ instead of n . One reason for this is that it makes S^2 unbiased for σ^2 , as next shown. Using the above theorems, the results of the last example, and the facts that $E(X^2) = \sigma^2 + \mu^2$ and $E(\bar{X}^2) = (\sigma^2/n) + \mu^2$, we have the following:

$$\begin{aligned} E(S^2) &= (n-1)^{-1} \left(\sum_{i=1}^n E(X_i^2) - nE(\bar{X}^2) \right) \\ &= (n-1)^{-1} \{ n\sigma^2 + n\mu^2 - n[(\sigma^2/n) + \mu^2] \} \\ &= \sigma^2. \end{aligned} \quad (2.8.8)$$

Hence, S^2 is unbiased for σ^2 . ■

EXERCISES

2.8.1. Derive the second equality in expression (2.8.7).

2.8.2. Let X_1, X_2, X_3, X_4 be four iid random variables having the same pdf $f(x) = 2x$, $0 < x < 1$, zero elsewhere. Find the mean and variance of the sum Y of these four random variables.

2.8.3. Let X_1 and X_2 be two independent random variables so that the variances of X_1 and X_2 are $\sigma_1^2 = k$ and $\sigma_2^2 = 2$, respectively. Given that the variance of $Y = 3X_2 - X_1$ is 25, find k .

2.8.4. If the independent variables X_1 and X_2 have means μ_1 , μ_2 and variances σ_1^2 , σ_2^2 , respectively, show that the mean and variance of the product $Y = X_1 X_2$ are $\mu_1 \mu_2$ and $\sigma_1^2 \sigma_2^2 + \mu_1^2 \sigma_2^2 + \mu_2^2 \sigma_1^2$, respectively.

2.8.5. Find the mean and variance of the sum $Y = \sum_{i=1}^5 X_i$, where X_1, \dots, X_5 are iid, having pdf $f(x) = 6x(1-x)$, $0 < x < 1$, zero elsewhere.

2.8.6. Determine the mean and variance of the sample mean $\bar{X} = 5^{-1} \sum_{i=1}^5 X_i$, where X_1, \dots, X_5 is a random sample from a distribution having pdf $f(x) = 4x^3$, $0 < x < 1$, zero elsewhere.

2.8.7. Let X and Y be random variables with $\mu_1 = 1$, $\mu_2 = 4$, $\sigma_1^2 = 4$, $\sigma_2^2 = 6$, $\rho = \frac{1}{2}$. Find the mean and variance of the random variable $Z = 3X - 2Y$.

2.8.8. Let X and Y be independent random variables with means μ_1 , μ_2 and variances σ_1^2 , σ_2^2 . Determine the correlation coefficient of X and $Z = X - Y$ in terms of μ_1 , μ_2 , σ_1^2 , σ_2^2 .

2.8.9. Let μ and σ^2 denote the mean and variance of the random variable X . Let $Y = c + bX$, where b and c are real constants. Show that the mean and variance of Y are, respectively, $c + b\mu$ and $b^2\sigma^2$.

2.8.10. Determine the correlation coefficient of the random variables X and Y if $\text{var}(X) = 4$, $\text{var}(Y) = 2$, and $\text{var}(X + 2Y) = 15$.

2.8.11. Let X and Y be random variables with means μ_1 , μ_2 ; variances σ_1^2 , σ_2^2 ; and correlation coefficient ρ . Show that the correlation coefficient of $W = aX + b$, $a > 0$, and $Z = cY + d$, $c > 0$, is ρ .

2.8.12. A person rolls a die, tosses a coin, and draws a card from an ordinary deck. He receives \$3 for each point up on the die, \$10 for a head and \$0 for a tail, and \$1 for each spot on the card (jack = 11, queen = 12, king = 13). If we assume that the three random variables involved are independent and uniformly distributed, compute the mean and variance of the amount to be received.

2.8.13. Let X_1 and X_2 be independent random variables with nonzero variances. Find the correlation coefficient of $Y = X_1X_2$ and X_1 in terms of the means and variances of X_1 and X_2 .

2.8.14. Let X_1 and X_2 have a joint distribution with parameters μ_1 , μ_2 , σ_1^2 , σ_2^2 , and ρ . Find the correlation coefficient of the linear functions of $Y = a_1X_1 + a_2X_2$ and $Z = b_1X_1 + b_2X_2$ in terms of the real constants a_1 , a_2 , b_1 , b_2 , and the parameters of the distribution.

2.8.15. Let X_1 , X_2 , and X_3 be random variables with equal variances but with correlation coefficients $\rho_{12} = 0.3$, $\rho_{13} = 0.5$, and $\rho_{23} = 0.2$. Find the correlation coefficient of the linear functions $Y = X_1 + X_2$ and $Z = X_2 + X_3$.

2.8.16. Find the variance of the sum of 10 random variables if each has variance 5 and if each pair has correlation coefficient 0.5.

2.8.17. Let X and Y have the parameters μ_1 , μ_2 , σ_1^2 , σ_2^2 , and ρ . Show that the correlation coefficient of X and $[Y - \rho(\sigma_2/\sigma_1)X]$ is zero.

2.8.18. Let S^2 be the sample variance of a random sample from a distribution with variance $\sigma^2 > 0$. Since $E(S^2) = \sigma^2$, why isn't $E(S) = \sigma$?

Hint: Use Jensen's inequality to show that $E(S) < \sigma$.

Chapter 3

Some Special Distributions

3.1 The Binomial and Related Distributions

In Chapter 1 we introduced the *uniform distribution* and the *hypergeometric distribution*. In this chapter we discuss some other important distributions of random variables frequently used in statistics. We begin with the binomial and related distributions.

A **Bernoulli experiment** is a random experiment, the outcome of which can be classified in but one of two mutually exclusive and exhaustive ways, for instance, success or failure (e.g., female or male, life or death, nondefective or defective). A sequence of **Bernoulli trials** occurs when a Bernoulli experiment is performed several independent times so that the probability of success, say p , remains the same from trial to trial. That is, in such a sequence, we let p denote the probability of success on each trial.

Let X be a random variable associated with a Bernoulli trial by defining it as follows:

$$X(\text{success}) = 1 \quad \text{and} \quad X(\text{failure}) = 0.$$

That is, the two outcomes, success and failure, are denoted by one and zero, respectively. The pmf of X can be written as

$$p(x) = p^x(1-p)^{1-x}, \quad x = 0, 1, \tag{3.1.1}$$

and we say that X has a **Bernoulli distribution**. The expected value of X is

$$\mu = E(X) = (0)(1-p) + (1)(p) = p,$$

and the variance of X is

$$\sigma^2 = \text{var}(X) = p^2(1-p) + (1-p)^2p = p(1-p).$$

It follows that the standard deviation of X is $\sigma = \sqrt{p(1-p)}$.

In a sequence of n independent Bernoulli trials, where the probability of success remains constant, let X_i denote the Bernoulli random variable associated with the

i th trial. An observed sequence of n Bernoulli trials is then an n -tuple of zeros and ones. In such a sequence of Bernoulli trials, we are often interested in the total number of successes and not in the order of their occurrence. If we let the random variable X equal the number of observed successes in n Bernoulli trials, the possible values of X are $0, 1, 2, \dots, n$. If x successes occur, where $x = 0, 1, 2, \dots, n$, then $n - x$ failures occur. The number of ways of selecting the x positions for the x successes in the n trials is

$$\binom{n}{x} = \frac{n!}{x!(n-x)!}.$$

Since the trials are independent and the probabilities of success and failure on each trial are, respectively, p and $1 - p$, the probability of each of these ways is $p^x(1 - p)^{n-x}$. Thus the pmf of X , say $p(x)$, is the sum of the probabilities of these $\binom{n}{x}$ mutually exclusive events; that is,

$$p(x) = \begin{cases} \binom{n}{x} p^x (1-p)^{n-x} & x = 0, 1, 2, \dots, n \\ 0 & \text{elsewhere.} \end{cases} \quad (3.1.2)$$

It is clear that $p(x) \geq 0$. To verify that $p(x)$ sums to 1 over its range, recall the binomial series expression (1.3.7) of Chapter 1, which is:

$$(a+b)^n = \sum_{x=0}^n \binom{n}{x} b^x a^{n-x},$$

for n a positive integer. Thus,

$$\begin{aligned} \sum_x p(x) &= \sum_{x=0}^n \binom{n}{x} p^x (1-p)^{n-x} \\ &= [(1-p) + p]^n = 1. \end{aligned}$$

Therefore, $p(x)$ satisfies the conditions of being a pmf of a random variable X of the discrete type. A random variable X that has a pmf of the form of $p(x)$ is said to have a **binomial distribution**, and any such $p(x)$ is called a **binomial pmf**. A binomial distribution is denoted by the symbol $b(n, p)$. The constants n and p are called the **parameters** of the binomial distribution.

Example 3.1.1 (Computation of Binomial Probabilities). Suppose we roll a fair six-sided die 3 times. What is the probability of getting exactly 2 sixes? For our notation, let X be the number of sixes obtained in the 3 rolls. Then X has a binomial distribution with $n = 3$ and $p = 1/6$. Hence,

$$P(X = 2) = p(2) = \binom{3}{2} \left(\frac{1}{6}\right)^2 \left(\frac{5}{6}\right)^1 = 0.06944.$$

We can do this calculation with a hand calculator. Suppose, though, we want to determine the probability of at least 16 sixes in 60 rolls. Let Y be the number of sixes in 60 rolls. Then our desired probability is given by the series

$$P(Y \geq 16) = \sum_{j=16}^{60} \binom{60}{j} \left(\frac{1}{6}\right)^j \left(\frac{5}{6}\right)^{60-j},$$

which is not a simple calculation. Most statistical packages provide procedures to calculate binomial probabilities. In R, if Y is $b(n, p)$ then the cdf of Y is computed as $P(Y \leq y) = \text{pbinom}(y, n, p)$. Hence, for our example, using R we compute the $P(Y \geq 16)$ as

$$P(Y \geq 16) = 1 - P(Y \leq 15) = 1 - \text{pbinom}(15, 60, 1/6) = 0.0338.$$

The R function `dbinom` computes the pmf of a binomial distribution. For instance, to compute the probability that $Y = 11$, we use the R code: `dbinom(11, 60, 1/6)`, which computes to 0.1246. ■

The mgf of a binomial distribution is easily obtained as follows:

$$\begin{aligned} M(t) &= \sum_x e^{tx} p(x) = \sum_{x=0}^n e^{tx} \binom{n}{x} p^x (1-p)^{n-x} \\ &= \sum_{x=0}^n \binom{n}{x} (pe^t)^x (1-p)^{n-x} \\ &= [(1-p) + pe^t]^n \end{aligned}$$

for all real values of t . The mean μ and the variance σ^2 of X may be computed from $M(t)$. Since

$$M'(t) = n[(1-p) + pe^t]^{n-1} (pe^t)$$

and

$$M''(t) = n[(1-p) + pe^t]^{n-1} (pe^t) + n(n-1)[(1-p) + pe^t]^{n-2} (pe^t)^2,$$

it follows that

$$\mu = M'(0) = np$$

and

$$\sigma^2 = M''(0) - \mu^2 = np + n(n-1)p^2 - (np)^2 = np(1-p).$$

Suppose Y has the $b(60, 1/6)$ distribution as discussed in Example 3.1.1. Then $E(Y) = 60(1/6) = 10$ and $\text{Var}(Y) = 60(1/6)(5/6) = 8.33$

Example 3.1.2. If the mgf of a random variable X is

$$M(t) = (\frac{2}{3} + \frac{1}{3}e^t)^5,$$

then X has a binomial distribution with $n = 5$ and $p = \frac{1}{3}$; that is, the pmf of X is

$$p(x) = \begin{cases} \binom{5}{x} \left(\frac{1}{3}\right)^x \left(\frac{2}{3}\right)^{5-x} & x = 0, 1, 2, \dots, 5 \\ 0 & \text{elsewhere.} \end{cases}$$

Here $\mu = np = \frac{5}{3}$ and $\sigma^2 = np(1-p) = \frac{10}{9}$. ■

Example 3.1.3. If Y is $b(n, \frac{1}{3})$, then $P(Y \geq 1) = 1 - P(Y = 0) = 1 - (\frac{2}{3})^n$. Suppose that we wish to find the smallest value of n that yields $P(Y \geq 1) > 0.80$. We have $1 - (\frac{2}{3})^n > 0.80$ and $0.20 > (\frac{2}{3})^n$. Either by inspection or by use of logarithms, we see that $n = 4$ is the solution. That is, the probability of at least one success throughout $n = 4$ independent repetitions of a random experiment with probability of success $p = \frac{1}{3}$ is greater than 0.80. ■

Example 3.1.4. Let the random variable Y be equal to the number of successes throughout n independent repetitions of a random experiment with probability p of success. That is, Y is $b(n, p)$. The ratio Y/n is called the relative frequency of success. Recall expression (1.10.3), the second version of Chebyshev's inequality (Theorem 1.10.3). Applying this result, we have for all $\epsilon > 0$ that

$$P\left(\left|\frac{Y}{n} - p\right| \geq \epsilon\right) \leq \frac{\text{Var}(Y/n)}{\epsilon^2} = \frac{p(1-p)}{n\epsilon^2}$$

[Exercise 3.1.3 asks for the determination of $\text{Var}(Y/n)$]. Now, for every fixed $\epsilon > 0$, the right-hand member of the preceding inequality is close to zero for sufficiently large n . That is,

$$\lim_{n \rightarrow \infty} P\left(\left|\frac{Y}{n} - p\right| \geq \epsilon\right) = 0$$

and

$$\lim_{n \rightarrow \infty} P\left(\left|\frac{Y}{n} - p\right| < \epsilon\right) = 1.$$

Since this is true for every fixed $\epsilon > 0$, we see, in a certain sense, that the relative frequency of success is for large values of n , close to the probability of p of success. This result is one form of the **Weak Law of Large Numbers**. It was alluded to in the initial discussion of probability in Chapter 1 and is considered again, along with related concepts, in Chapter 5. ■

Example 3.1.5. Let the independent random variables X_1, X_2, X_3 have the same cdf $F(x)$. Let Y be the middle value of X_1, X_2, X_3 . To determine the cdf of Y , say $F_Y(y) = P(Y \leq y)$, we note that $Y \leq y$ if and only if at least two of the random variables X_1, X_2, X_3 are less than or equal to y . Let us say that the i th “trial” is a success if $X_i \leq y$, $i = 1, 2, 3$; here each “trial” has the probability of success $F(y)$. In this terminology, $F_Y(y) = P(Y \leq y)$ is then the probability of at least two successes in three independent trials. Thus

$$F_Y(y) = \binom{3}{2} [F(y)]^2 [1 - F(y)] + [F(y)]^3.$$

If $F(x)$ is a continuous cdf so that the pdf of X is $F'(x) = f(x)$, then the pdf of Y is

$$f_Y(y) = F'_Y(y) = 6[F(y)][1 - F(y)]f(y). \blacksquare$$

Suppose we have several independent binomial distributions with the same probability of success. Then it makes sense that the sum of these random variables is binomial, as shown in the following theorem.

Theorem 3.1.1. Let X_1, X_2, \dots, X_m be independent random variables such that X_i has binomial $b(n_i, p)$ distribution, for $i = 1, 2, \dots, m$. Let $Y = \sum_{i=1}^m X_i$. Then Y has a binomial $b(\sum_{i=1}^m n_i, p)$ distribution.

Proof: The mgf of X_i is $M_{X_i}(t) = (1 - p + pe^t)^{n_i}$. By independence it follows from Theorem 2.6.1 that

$$M_Y(t) = \prod_{i=1}^m (1 - p + pe^t)^{n_i} = (1 - p + pe^t)^{\sum_{i=1}^m n_i}.$$

Hence, Y has a binomial $b(\sum_{i=1}^m n_i, p)$ distribution. ■

For the remainder of this section, we discuss some important distributions that are related to the binomial distribution.

3.1.1 Negative Binomial and Geometric Distributions

Consider a sequence of independent Bernoulli trials with constant probability p of success. Let the random variable Y denote the total number of failures in this sequence before the r th success, that is, $Y + r$ is equal to the number of trials necessary to produce exactly r successes with the last trial as a success. Here r is a fixed positive integer. To determine the pmf of Y , let y be an element of $\{y : y = 0, 1, 2, \dots\}$. Then, since the trials are independent, $P(Y = y)$ is equal to the product of the probability of obtaining exactly $r - 1$ successes in the first $y + r - 1$ trials times the probability p of a success on the $(y + r)$ th trial. Thus the pmf of Y is

$$p_Y(y) = \begin{cases} \binom{y+r-1}{r-1} p^r (1-p)^y & y = 0, 1, 2, \dots \\ 0 & \text{elsewhere.} \end{cases} \quad (3.1.3)$$

A distribution with a pmf of the form $p_Y(y)$ is called a **negative binomial distribution** and any such $p_Y(y)$ is called a negative binomial pmf. The distribution derives its name from the fact that $p_Y(y)$ is a general term in the expansion of $p^r[1 - (1 - p)]^{-r}$. It is left as an exercise to show that the mgf of this distribution is $M(t) = p^r[1 - (1 - p)e^t]^{-r}$, for $t < -\log(1 - p)$. The R call to compute $P(y \leq y)$ is `pnbinom(y, r, p)`.

Example 3.1.6. Suppose the probability that a person has blood type B is 0.12. In order to conduct a study concerning people with blood type B, patients are sampled independently of one another until 10 are obtained who have blood type B. Determine the probability that at most 30 patients have to have their blood type determined. Let Y have a negative binomial distribution with $p = 0.12$ and $r = 10$. Then, the desired probability is

$$P(Y \leq 20) = \sum_{j=0}^{20} \binom{j+9}{9} 0.12^{10} 0.88^j.$$

Its computation in R is `pnbinom(20, 10, 0.12) = 0.0019`. ■

If $r = 1$, then Y has the pmf

$$p(y) = p(1 - p)^y, \quad y = 0, 1, 2, \dots, \quad (3.1.4)$$

zero elsewhere, and the mgf $M(t) = p[1 - (1 - p)e^t]^{-1}$. In this special case, $r = 1$, we say that Y has a **geometric distribution**. In terms of Bernoulli trials, Y is the number of failures until the first success. The geometric distribution was first discussed in Example 1.6.3 of Chapter 1. For the last example, the probability that exactly 11 patients have to have their blood type determined before the first patient with type B blood is found is given by $.88^{11}0.12$. This is computed in R by `dgeom(11, 0.12) = 0.0294`.

3.1.2 Multinomial Distribution

The binomial distribution is generalized to the multinomial distribution as follows. Let a random experiment be repeated n independent times. On each repetition, there is one and only one outcome from one of k categories. Call the categories C_1, C_2, \dots, C_k . For example, the upface of a roll of a six-sided die. Then the categories are $C_i = \{i\}$, $i = 1, 2, \dots, 6$. For $i = 1, \dots, k$, let p_i be the probability that the outcome is an element of C_i and assume that p_i remains constant throughout the n independent repetitions. Define the random variable X_i to be equal to the number of outcomes that are elements of C_i , $i = 1, 2, \dots, k - 1$. Because $X_k = n - X_1 - \dots - X_{k-1}$, X_k is determined by the other X_i 's. Hence, for the joint distribution of interest we need only consider X_1, X_2, \dots, X_{k-1} .

The joint pmf of $(X_1, X_2, \dots, X_{k-1})$ is

$$P(X_1 = x_1, X_2 = x_2, \dots, X_{k-1} = x_{k-1}) = \frac{n!}{x_1! \cdots x_{k-1}! x_k!} p_1^{x_1} \cdots p_{k-1}^{x_{k-1}} p_k^{x_k}, \quad (3.1.5)$$

for all x_1, x_2, \dots, x_{k-1} that are nonnegative integers and such that $x_1 + x_2 + \dots + x_{k-1} \leq n$, where $x_k = n - x_1 - \dots - x_{k-1}$ and $p_k = 1 - \sum_{j=1}^{k-1} p_j$. We next show that expression (3.1.5) is correct. The number of distinguishable arrangements of $x_1 C_1$ s, $x_2 C_2$ s, \dots , $x_k C_k$ s is

$$\binom{n}{x_1} \binom{n-x_1}{x_2} \cdots \binom{n-x_1-\cdots-x_{k-2}}{x_{k-1}} = \frac{n!}{x_1! x_2! \cdots x_k!}$$

and the probability of each of these distinguishable arrangements is

$$p_1^{x_1} p_2^{x_2} \cdots p_k^{x_k}.$$

Hence the product of these two latter expressions gives the correct probability, which is in agreement with expression (3.1.5).

We say that $(X_1, X_2, \dots, X_{k-1})$ has a **multinomial distribution** with parameters n and p_1, \dots, p_{k-1} . The joint mgf of $(X_1, X_2, \dots, X_{k-1})$ is $M(t_1, \dots, t_{k-1}) = E(\exp\{\sum_{i=1}^{k-1} t_i X_i\})$, i.e.,

$$M(t_1, \dots, t_{k-1}) = \sum \cdots \sum \frac{n!}{x_1! \cdots x_{k-1}! x_k!} (p_1 e^{t_1})^{x_1} \cdots (p_{k-1} e^{t_{k-1}})^{x_{k-1}} p_k^{x_k},$$

where the multiple sum is taken over all nonnegative integers and such that $x_1 + x_2 + \dots + x_{k-1} \leq n$. Let $m = \sum_{i=1}^{k-1} p_i e^{t_i} + p_{k-1}$. Recall that $x_k = n - \sum_{i=1}^{k-1} x_i$. Then since $m > 0$, we have

$$\begin{aligned} M(t_1, \dots, t_{k-1}) &= m^n \sum \dots \sum \frac{n!}{x_1! \dots x_{k-1}! x_k!} \\ &\quad \times \left(\frac{p_1 e^{t_1}}{m} \right)^{x_1} \dots \left(\frac{p_{k-1} e^{t_{k-1}}}{m} \right)^{x_{k-1}} \left(\frac{p_k}{m} \right)^{x_k} \\ &= m^n \times 1 = \left(\sum_{i=1}^{k-1} p_i e^{t_i} + p_{k-1} \right)^n, \end{aligned} \quad (3.1.6)$$

where we have used the property that sum of a pmf over its support is 1.

We can use the joint mgf to determine marginal distributions. The mgf of X_i is

$$M(0, \dots, 0, t_i, 0, \dots, 0) = (p_i e^{t_i} + (1 - p_i))^n;$$

hence, X_i is binomial with parameters n and p_i . The mgf of (X_i, X_j) , $i < j$, is

$$M(0, \dots, 0, t_i, 0, \dots, 0, t_j, 0, \dots, 0) = (p_i e^{t_i} + p_j e^{t_j} + (1 - p_i - p_j))^n;$$

so that (X_i, X_j) has a multinomial distribution with parameters n , p_i , and p_j . At times, we say that (X_1, X_2) has a **trinomial distribution**.

Another distribution of interest is the conditional distribution of X_i given X_j . For convenience, we select $i = 2$ and $j = 1$. We know that (X_1, X_2) is multinomial with parameters n and p_1 and p_2 and that X_1 is binomial with parameters n and p_1 . Thus, the conditional pmf is,

$$\begin{aligned} p_{X_2|X_1}(x_2 | x_1) &= \frac{p_{X_1, X_2}(x_1, x_2)}{p_{X_1}(x_1)} \\ &= \frac{x_1!(n - x_1)!}{n! p_1^{x_1} [1 - p_1]^{n-x_1}} \frac{n! p_1^{x_1} p_2^{x_2} [1 - (p_1 + p_2)]^{n-(x_1+x_2)}}{x_1! x_2! [n - (x_1 + x_2)]!} \\ &= \binom{n - x_1}{x_2} \frac{p_2^{x_2}}{(1 - p_1)^{x_2}} \frac{[(1 - p_1) - p_2]^{n-x_1-x_2}}{(1 - p_1)^{n-x_1-x_2}} \\ &= \binom{n - x_1}{x_2} \left(\frac{p_2}{1 - p_1} \right)^{x_2} \left(1 - \frac{p_2}{1 - p_1} \right)^{n-x_1-x_2}, \end{aligned}$$

for $0 \leq x_2 \leq n - x_1$. Note that $p_2 < 1 - p_1$. Thus, the conditional distribution of X_2 given $X_1 = x_1$ is binomial with parameters $n - x_1$ and $p_2/(1 - p_1)$.

Based on the conditional distribution of X_2 given X_1 , we have $E(X_2 | X_1) = (n - X_1)p_2/(1 - p_1)$. Let ρ_{12} be the correlation coefficient between X_1 and X_2 . Since the conditional mean is linear with slope $-p_2/(1 - p_1)$, $\sigma_2 = \sqrt{np_2(1 - p_2)}$, and $\sigma_1 = \sqrt{np_1(1 - p_1)}$, it follows from expression (2.5.4) that

$$\rho_{12} = -\frac{p_2}{1 - p_1} \frac{\sigma_1}{\sigma_2} = -\sqrt{\frac{p_1 p_2}{(1 - p_1)(1 - p_2)}}.$$

Because the support of X_1 and X_2 has the constraint $x_1 + x_2 \leq n$, the negative correlation is not surprising.

3.1.3 Hypergeometric Distribution

In Chapter 1, for a particular problem, we introduced the hypergeometric distribution; see expression (1.6.4). We now formally define it. Suppose we have a lot of N items of which D are defective. Let X denote the number of defective items in a sample of size n . If the sampling is done with replacement and the items are chosen at random, then X has a binomial distribution with parameters n and D/N . In this case the mean and variance of X are $n(D/N)$ and $n(D/N)[(N - D)/N]$, respectively. Suppose, however, that the sampling is without replacement, which is often the case in practice. The pmf of X follows by noting in this case that each of the $\binom{N}{n}$ samples are equilike and that there are $\binom{N-D}{n-x} \binom{D}{x}$ samples that have x defective items. Hence, the pmf of X is

$$p(x) = \frac{\binom{N-D}{n-x} \binom{D}{x}}{\binom{N}{n}}, \quad x = 0, 1, \dots, n, \quad (3.1.7)$$

where, as usual, a binomial coefficient is taken to be 0 when the top value is less than the bottom value. We say that X has a **hypergeometric distribution** with parameters (N, D, n) .

The mean of X is

$$\begin{aligned} E(X) &= \sum_{x=0}^n x p(x) = \sum_{x=1}^n x \frac{\binom{N-D}{n-x} [D(D-1)!]/[x(x-1)!(D-x)!]}{[N(N-1)!]/[(N-n)!n(n-1)!]} \\ &= n \frac{D}{N} \sum_{x=1}^n \binom{(N-1)-(D-1)}{(n-1)-(x-1)} \binom{D-1}{x-1} \binom{N-1}{n-1}^{-1} = n \frac{D}{N}. \end{aligned}$$

In the next-to-last step, we used the fact that the probabilities of a hypergeometric $(N-1, D-1, n-1)$ distribution summed over its entire range is 1. So the means for both types of sampling (with and without replacement) are the same. The variances, though, differ. As Exercise 3.1.31 shows, the variance of a hypergeometric (N, D, n) is

$$\text{Var}(X) = n \frac{D}{N} \frac{N-D}{N} \frac{N-n}{N-1}. \quad (3.1.8)$$

The last term is often thought of as the correction term when sampling without replacement. Note that it is close to 1 if N is much larger than n .

The pmf (3.1.7) can be computed in R with the code `dhyper(x, D, N-D, n)`. Suppose we draw 2 cards from a well shuffled standard deck of 52 cards and record the number of aces. The next R segment shows the probabilities over the range $\{0, 1, 2\}$ for sampling with and without replacement, respectively:

```
rng <- 0:2; dbinom(rng, 2, 1/13); dhyper(rng, 4, 48, 2)
[1] 0.85207101 0.14201183 0.00591716
[1] 0.850678733 0.144796380 0.004524887
```

Notice how close the probabilities are.

EXERCISES

3.1.1. If the mgf of a random variable X is $(\frac{1}{3} + \frac{2}{3}e^t)^5$, find $P(X = 2 \text{ or } 3)$. Verify using the R function `dbinom`.

3.1.2. The mgf of a random variable X is $(\frac{2}{3} + \frac{1}{3}e^t)^9$.

- (a) Show that

$$P(\mu - 2\sigma < X < \mu + 2\sigma) = \sum_{x=1}^5 \binom{9}{x} \left(\frac{1}{3}\right)^x \left(\frac{2}{3}\right)^{9-x}.$$

- (b) Use R to compute the probability in Part (a).

3.1.3. If X is $b(n, p)$, show that

$$E\left(\frac{X}{n}\right) = p \quad \text{and} \quad E\left[\left(\frac{X}{n} - p\right)^2\right] = \frac{p(1-p)}{n}.$$

3.1.4. Let the independent random variables X_1, X_2, \dots, X_{40} be iid with the common pdf $f(x) = 3x^2$, $0 < x < 1$, zero elsewhere. Find the probability that at least 35 of the X_i 's exceed $\frac{1}{2}$.

3.1.5. Over the years, the percentage of candidates passing an entrance exam to a prestigious law school is 20%. At one of the testing centers, a group of 50 candidates take the exam and 20 pass. Is this odd? Answer on the basis that $X \geq 20$ where X is the number that pass in a group of 50 when the probability of a pass is 0.2.

3.1.6. Let Y be the number of successes throughout n independent repetitions of a random experiment with probability of success $p = \frac{1}{4}$. Determine the smallest value of n so that $P(1 \leq Y) \geq 0.70$.

3.1.7. Let the independent random variables X_1 and X_2 have binomial distribution with parameters $n_1 = 3$, $p = \frac{2}{3}$ and $n_2 = 4$, $p = \frac{1}{2}$, respectively. Compute $P(X_1 = X_2)$.

Hint: List the four mutually exclusive ways that $X_1 = X_2$ and compute the probability of each.

3.1.8. For this exercise, the reader must have access to a statistical package that obtains the binomial distribution. Hints are given for R code, but other packages can be used too.

- (a) Obtain the plot of the pmf for the $b(15, 0.2)$ distribution. Using R, the following commands return the plot:

```
x<-0:15; plot(dbinom(x,15,.2)^x)
```

- (b) Repeat part (a) for the binomial distributions with $n = 15$ and with $p = 0.10, 0.20, \dots, 0.90$. Comment on the shapes of the pmf's as p increases. Use the following R segment:

```
x<-0:15; par(mfrow=c(3,3)); p <- 1:9/10
for(j in p){plot(dbinom(x,15,j)^x); title(paste("p=",j))}
```

- (c) Let $Y = \frac{X}{n}$, where X has a $b(n, 0.05)$ distribution. Obtain the plots of the pmfs of Y for $n = 10, 20, 50, 200$. Comment on the plots (what do the plots seem to be converging to as n gets large?).

3.1.9. If $x = r$ is the unique mode of a distribution that is $b(n, p)$, show that

$$(n+1)p - 1 < r < (n+1)p.$$

This substantiates the comments made in Part (b) of Exercise 3.1.8.

Hint: Determine the values of x for which $p(x+1)/p(x) > 1$.

- 3.1.10.** Suppose X is $b(n, p)$. Then by definition the pmf is symmetric if and only if $p(x) = p(n-x)$, for $x = 0, \dots, n$. Show that the pmf is symmetric if and only if $p = 1/2$.

- 3.1.11.** Toss two nickels and three dimes at random. Make appropriate assumptions and compute the probability that there are more heads showing on the nickels than on the dimes.

3.1.12. Let X_1, X_2, \dots, X_{k-1} have a multinomial distribution.

- (a) Find the mgf of X_2, X_3, \dots, X_{k-1} .
- (b) What is the pmf of X_2, X_3, \dots, X_{k-1} ?
- (c) Determine the conditional pmf of X_1 given that $X_2 = x_2, \dots, X_{k-1} = x_{k-1}$.
- (d) What is the conditional expectation $E(X_1|x_2, \dots, x_{k-1})$?

3.1.13. Let X be $b(2, p)$ and let Y be $b(4, p)$. If $P(X \geq 1) = \frac{5}{9}$, find $P(Y \geq 1)$.

3.1.14. Let X have a binomial distribution with parameters n and $p = \frac{1}{3}$. Determine the smallest integer n can be such that $P(X \geq 1) \geq 0.85$.

3.1.15. Let X have the pmf $p(x) = (\frac{1}{3})(\frac{2}{3})^x$, $x = 0, 1, 2, 3, \dots$, zero elsewhere. Find the conditional pmf of X given that $X \geq 3$.

3.1.16. One of the numbers $1, 2, \dots, 6$ is to be chosen by casting an unbiased die. Let this random experiment be repeated five independent times. Let the random variable X_1 be the number of terminations in the set $\{x : x = 1, 2, 3\}$ and let the random variable X_2 be the number of terminations in the set $\{x : x = 4, 5\}$. Compute $P(X_1 = 2, X_2 = 1)$.

3.1.17. Show that the moment generating function of the negative binomial distribution is $M(t) = p^r[1 - (1-p)e^t]^{-r}$. Find the mean and the variance of this distribution.

Hint: In the summation representing $M(t)$, make use of the negative binomial series.¹

¹See, for example, *Mathematical Comments* referenced in the Preface.

3.1.18. One way of estimating the number of fish in a lake is the following **capture-recapture** sampling scheme. Suppose there are N fish in the lake where N is unknown. A specified number of fish T are captured, tagged, and released back to the lake. Then at a specified time and for a specified positive integer r , fish are captured until the r th tagged fish is caught. The random variable of interest is Y the number of nontagged fish caught.

- (a) What is the distribution of Y ? Identify all parameters.
- (b) What is $E(Y)$ and the $\text{Var}(Y)$?
- (c) The method of moment estimate of N is to set Y equal to the expression for $E(Y)$ and solve this equation for N . Call the solution \hat{N} . Determine \hat{N} .
- (d) Determine the mean and variance of \hat{N} .

3.1.19. Consider a multinomial trial with outcomes $1, 2, \dots, k$ and respective probabilities p_1, p_2, \dots, p_k . Let ps denote the R vector for (p_1, p_2, \dots, p_k) . Then a single random trial of this multinomial is computed with the command `multitrial(ps)`, where the required R functions are:²

```
psum <- function(v){
  p<-0; psum <- c()
  for(j in 1:length(v)){p<-p+v[j]; psum <- c(psum,p)}
  return(psum)}
multitrial <- function(p){
  pr <- c(0,psum(p))
  r <- runif(1); ic <- 0; j <- 1
  while(ic==0){if((r > pr[j]) && (r <= pr[j+1]))
    {multitrial <-j; ic<-1}; j<- j+1}
  return(multitrial)}
```

- (a) Compute 10 random trials if $\text{ps}=c(.3,.2,.2,.2,.1)$.
- (b) Compute 10,000 random trials for ps as in (a). Check to see how close the estimates of p_i are with p_i .

3.1.20. Using the experiment in part (a) of Exercise 3.1.19, consider a game when a person pays \$5 to play. If the trial results in a 1 or 2, she receives nothing; if a 3, she receives \$1; if a 4, she receives \$2; and if a 5, she receives \$20. Let G be her gain.

- (a) Determine $E(G)$.
- (b) Write R code that simulates the gain. Then simulate it 10,000 times, collecting the gains. Compute the average of these 10,000 gains and compare it with $E(G)$.

²Downloadable at the site listed in the Preface

3.1.21. Let X_1 and X_2 have a trinomial distribution. Differentiate the moment-generating function to show that their covariance is $-np_1p_2$.

3.1.22. If a fair coin is tossed at random five independent times, find the conditional probability of five heads given that there are at least four heads.

3.1.23. Let an unbiased die be cast at random seven independent times. Compute the conditional probability that each side appears at least once given that side 1 appears exactly twice.

3.1.24. Compute the measures of skewness and kurtosis of the binomial distribution $b(n, p)$.

3.1.25. Let

$$p(x_1, x_2) = \binom{x_1}{x_2} \left(\frac{1}{2}\right)^{x_1} \left(\frac{x_1}{15}\right), \quad \begin{array}{l} x_2 = 0, 1, \dots, x_1 \\ x_1 = 1, 2, 3, 4, 5, \end{array}$$

zero elsewhere, be the joint pmf of X_1 and X_2 . Determine

- (a) $E(X_2)$.
- (b) $u(x_1) = E(X_2|x_1)$.
- (c) $E[u(X_1)]$.

Compare the answers of parts (a) and (c).

Hint: Note that $E(X_2) = \sum_{x_1=1}^5 \sum_{x_2=0}^{x_1} x_2 p(x_1, x_2)$.

3.1.26. Three fair dice are cast. In 10 independent casts, let X be the number of times all three faces are alike and let Y be the number of times only two faces are alike. Find the joint pmf of X and Y and compute $E(6XY)$.

3.1.27. Let X have a geometric distribution. Show that

$$P(X \geq k + j | X \geq k) = P(X \geq j), \quad (3.1.9)$$

where k and j are nonnegative integers. Note that we sometimes say in this situation that X is **memoryless**.

3.1.28. Let X equal the number of independent tosses of a fair coin that are required to observe heads on consecutive tosses. Let u_n equal the n th Fibonacci number, where $u_1 = u_2 = 1$ and $u_n = u_{n-1} + u_{n-2}$, $n = 3, 4, 5, \dots$

- (a) Show that the pmf of X is

$$p(x) = \frac{u_{x-1}}{2^x}, \quad x = 2, 3, 4, \dots$$

- (b) Use the fact that

$$u_n = \frac{1}{\sqrt{5}} \left[\left(\frac{1+\sqrt{5}}{2} \right)^n - \left(\frac{1-\sqrt{5}}{2} \right)^n \right]$$

to show that $\sum_{x=2}^{\infty} p(x) = 1$.

3.1.29. Let the independent random variables X_1 and X_2 have binomial distributions with parameters n_1 , $p_1 = \frac{1}{2}$ and n_2 , $p_2 = \frac{1}{2}$, respectively. Show that $Y = X_1 - X_2 + n_2$ has a binomial distribution with parameters $n = n_1 + n_2$, $p = \frac{1}{2}$.

3.1.30. Consider a shipment of 1000 items into a factory. Suppose the factory can tolerate about 5% defective items. Let X be the number of defective items in a sample without replacement of size $n = 10$. Suppose the factory returns the shipment if $X \geq 2$.

- (a) Obtain the probability that the factory returns a shipment of items that has 5% defective items.
- (b) Suppose the shipment has 10% defective items. Obtain the probability that the factory returns such a shipment.
- (c) Obtain approximations to the probabilities in parts (a) and (b) using appropriate binomial distributions.

Note: If you do not have access to a computer package with a hypergeometric command, obtain the answer to (c) only. This is what would have been done in practice 20 years ago. If you have access to R, then the command `dhyper(x,D,N-D,n)` returns the probability in expression (3.1.7).

3.1.31. Show that the variance of a hypergeometric (N, D, n) distribution is given by expression (3.1.8).

Hint: First obtain $E[X(X - 1)]$ by proceeding in the same way as the derivation of the mean given in Section 3.1.3.

3.2 The Poisson Distribution

Recall that the following series expansion³ holds for all real numbers z :

$$1 + z + \frac{z^2}{2!} + \frac{z^3}{3!} + \cdots = \sum_{x=0}^{\infty} \frac{z^x}{x!} = e^z.$$

Consider the function $p(x)$ defined by

$$p(x) = \begin{cases} \frac{\lambda^x e^{-\lambda}}{x!} & x = 0, 1, 2, \dots \\ 0 & \text{elsewhere,} \end{cases} \quad (3.2.1)$$

where $\lambda > 0$. Since $\lambda > 0$, then $p(x) \geq 0$ and

$$\sum_{x=0}^{\infty} p(x) = \sum_{x=0}^{\infty} \frac{\lambda^x e^{-\lambda}}{x!} = e^{-\lambda} \sum_{x=0}^{\infty} \frac{\lambda^x}{x!} = e^{-\lambda} e^{\lambda} = 1;$$

³See, for example, the discussion on Taylor series in *Mathematical Comments* referenced in the Preface.

that is, $p(x)$ satisfies the conditions of being a pmf of a discrete type of random variable. A random variable that has a pmf of the form $p(x)$ is said to have a **Poisson distribution** with parameter λ , and any such $p(x)$ is called a **Poisson pmf** with parameter λ .

As the following remark shows, Poisson distributions occur in many areas of applications.

Remark 3.2.1. Consider a process that counts the number of certain events occurring over an interval of time; for example, the number of tornados that touch down in Michigan per year, the number of cars entering a parking lot between 8:00 and 12:00 on a weekday, the number of car accidents at a busy intersection per week, the number of typographical errors per page of a manuscript, and the number of blemishes on a manufactured car door. As in the third and fourth examples, the occurrences need not be over time. It is convenient, though, to use the time representation in the following derivation. Let X_t denote the number of occurrences of such a process over the interval $(0, t]$. The range of X_t is the set of nonnegative integers $\{0, 1, 2, \dots\}$. For a nonnegative integer k and a real number $t > 0$, denote the pmf of X_t by $P(X_t = k) = g(k, t)$. Under the following three axioms, we next show that X_t has a Poisson distribution.

1. $g(1, h) = \lambda h + o(h)$, for a constant $\lambda > 0$.
2. $\sum_{t=2}^{\infty} g(t, h) = o(h)$.
3. The number of occurrences in nonoverlapping intervals are independent of one another.

Here the $o(h)$ notation means that $o(h)/h \rightarrow 0$ as $h \rightarrow 0$. For instance, $h^2 = o(h)$ and $o(h) + o(h) = o(h)$. Note that the first two axioms imply that in a small interval of time h , either one or no events occur and that the probability of one event occurring is proportional to h .

By the method of induction, we now show that the distribution of X_t is Poisson with parameter λt . First, we obtain $g(k, t)$ for $k = 0$. Note that the boundary condition $g(0, 0) = 1$ is reasonable. No events occur in time $(0, t+h]$ if and only if no events occur in $(0, t]$ and no events occur in $(t, t+h]$. By Axioms (1) and (2), the probability that no events occur in the interval $(0, h]$ is $1 - \lambda h + o(h)$. Further, the intervals $(0, t]$ and $(t, t+h]$ do not overlap. Hence, by Axiom (3) we have

$$g(0, t+h) = g(0, t)[1 - \lambda h + o(h)]. \quad (3.2.2)$$

That is,

$$\frac{g(0, t+h) - g(0, t)}{h} = -\lambda g(0, t) + \frac{g(0, t)o(h)}{h} \rightarrow -\lambda g(0, t), \quad \text{as } h \rightarrow 0.$$

Thus, $g(0, t)$ satisfies the differential equation

$$\frac{dt g(0, t)}{g(0, t)} = -\lambda$$

Integrating both side with respect to t , we have for some constant c that

$$\log g(0, t) = -\lambda t + c \text{ or } g(0, t) = e^{-\lambda t} e^c.$$

Finally, using the boundary condition $g(0, 0) = 1$, we have $e^c = 1$. Hence,

$$g(0, t) = e^{-\lambda t}. \quad (3.2.3)$$

So the result holds for $k = 0$.

For the remainder of the proof, assume that, for k a nonnegative integer, $g(k, t) = e^{-\lambda t}(\lambda t)^k/k!$. By induction, the proof follows if we can show that the result holds for $g(k+1, t)$. Another reasonable boundary condition is $g(k+1, 0) = 0$. Consider $g(k+1, t+h)$. In order to have $k+1$ occurrences in $(0, t+h]$ either there are $k+1$ occurrences in $(0, t]$ and no occurrences in $(t, t+h]$ or there are k occurrences in $(0, t]$ and one occurrence in $(t, t+h]$. Because these events are disjoint we have by the independence of Axiom 3 that

$$g(k+1, t+h) = g(k+1, t)[1 - \lambda h + o(h)] + g(k, t)[\lambda h + o(h)],$$

that is,

$$\frac{g(k+1, t+h) - g(k+1, t)}{h} = -\lambda g(k+1, t) + g(k, t)\lambda + [g(k+1, t) + g(k, t)]\frac{o(h)}{h}.$$

Letting $h \rightarrow 0$ and using the value of $g(k, t)$, we obtain the differential equation

$$\frac{d}{dt}g(k+1, t) = -\lambda g(k+1, t) + \lambda e^{-\lambda t}[(\lambda t)^k/k!].$$

This is a linear differential equation of first order. Appealing to a theorem in differential equations, its solution is

$$e^{\int \lambda dt}g(k+1, t) = \int e^{\int \lambda dt}\lambda e^{-\lambda t}[(\lambda t)^k/k!]dt + c.$$

Using the boundary condition $g(k+1, 0) = 0$ and carrying out the integration, we obtain

$$g(k+1, t) = e^{-\lambda t}[(\lambda t)^{k+1}/(k+1)!]$$

Therefore, X_t has a Poisson distribution with parameter λt . ■

Let X have a Poisson distribution with parameter λ . The mgf of X is given by

$$\begin{aligned} M(t) &= \sum_{x=0}^{\infty} e^{tx} p(x) = \sum_{x=0}^{\infty} e^{tx} \frac{\lambda^x e^{-\lambda}}{x!} \\ &= e^{-\lambda} \sum_{x=0}^{\infty} \frac{(\lambda e^t)^x}{x!} \\ &= e^{-\lambda} e^{\lambda e^t} = e^{\lambda(e^t - 1)} \end{aligned}$$

for all real values of t . Since

$$M'(t) = e^{\lambda(e^t - 1)}(\lambda e^t)$$

and

$$M''(t) = e^{\lambda(e^t - 1)}\lambda e^t \lambda e^t + e^{\lambda(e^t - 1)}\lambda e^t$$

then

$$\mu = M'(0) = \lambda$$

and

$$\sigma^2 = M''(0) - \mu^2 = \lambda^2 + \lambda - \lambda^2 = \lambda.$$

That is, a Poisson distribution has $\mu = \sigma^2 = \lambda > 0$.

If X has a Poisson distribution with parameter λ , then $P(X = k)$ is computed by the R command `dpois(k, lambda)` and the cumulative probability $P(X \leq k)$ is calculated by `ppois(k, lambda)`.

Example 3.2.1. Let X be the number of automobile accidents at a busy intersection per week. Suppose that X has a Poisson distribution with $\lambda = 2$. Then the expected number of accidents per week is 2 and the standard deviation of the number of accidents is $\sqrt{2}$. The probability of at least one accident in a week is

$$P(X \geq 1) = 1 - P(X = 0) = 1 - e^{-2} = 1 - \text{dpois}(0, 2) = 0.8647$$

and the probability that there are between 3 and 8 (inclusive) accidents is

$$P(3 \leq X \leq 8) = P(X \leq 8) - P(X \leq 2) = \text{ppois}(8, 2) - \text{ppois}(2, 2) = 0.3231.$$

Suppose we want to determine the probability that there are exactly 16 accidents in a 4 week period. By Remark 3.2.1, the number of accidents over a 4 week period has a Poisson distribution with parameter $2 \times 4 = 8$. So the desired probability is `dpois(16, 8) = 0.0045`. The following R code computes a spiked plot of the pmf of X over $\{0, 1, \dots, 7\}$, a subset of the range of X .

```
rng=0:7; y=dpois(rng,2); plot(y~rng,type="h",ylab="pmf",xlab="Rng");
points(y~rng,pch=16,cex=2)
```

■

Example 3.2.2. Let the probability of exactly one blemish in 1 foot of wire be about $\frac{1}{1000}$ and let the probability of two or more blemishes in that length be, for all practical purposes, zero. Let the random variable X be the number of blemishes in 3000 feet of wire. If we assume the independence of the number of blemishes in nonoverlapping intervals, then by Remark 3.2.1 the postulates of the Poisson process are approximated, with $\lambda = \frac{1}{1000}$ and $t = 3000$. Thus X has an approximate Poisson distribution with mean $3000(\frac{1}{1000}) = 3$. For example, the probability that there are five or more blemishes in 3000 feet of wire is

$$P(X \geq 5) = \sum_{k=5}^{\infty} \frac{3^k e^{-3}}{k!} = 1 - \text{ppois}(4, 3) = 0.1847. \blacksquare$$

The Poisson distribution satisfies the following important additive property.

Theorem 3.2.1. Suppose X_1, \dots, X_n are independent random variables and suppose X_i has a Poisson distribution with parameter λ_i . Then $Y = \sum_{i=1}^n X_i$ has a Poisson distribution with parameter $\sum_{i=1}^n \lambda_i$.

Proof: We obtain the result by determining the mgf of Y , which by Theorem 2.6.1 is given by

$$M_Y(t) = E(e^{tY}) = \prod_{i=1}^n e^{\lambda_i(e^t - 1)} = e^{\sum_{i=1}^n \lambda_i(e^t - 1)}.$$

By the uniqueness of mgfs, we conclude that Y has a Poisson distribution with parameter $\sum_{i=1}^n \lambda_i$. ■

Example 3.2.3 (Example 3.2.2, Continued). Suppose, as in Example 3.2.2, that a bail of wire consists of 3000 feet. Based on the information in the example, we expect three blemishes in a bail of wire, and the probability of five or more blemishes is 0.1847. Suppose in a sampling plan, three bails of wire are selected at random and we compute the mean number of blemishes in the wire. Now suppose we want to determine the probability that the mean of the three observations has five or more blemishes. Let X_i be the number of blemishes in the i th bail of wire for $i = 1, 2, 3$. Then X_i has a Poisson distribution with parameter 3. The mean of X_1, X_2 , and X_3 is $\bar{X} = 3^{-1} \sum_{i=1}^3 X_i$, which can also be expressed as $Y/3$, where $Y = \sum_{i=1}^3 X_i$. By the last theorem, because the bails are independent of one another, Y has a Poisson distribution with parameter $\sum_{i=1}^3 3 = 9$. Hence, the desired probability is

$$P(\bar{X} \geq 5) = P(Y \geq 15) = 1 - \text{ppois}(14, 9) = 0.0415.$$

Hence, while it is not too odd that a bail has five or more blemishes (probability is 0.1847), it is unusual (probability is 0.0415) that three independent bails of wire average five or more blemishes. ■

EXERCISES

3.2.1. If the random variable X has a Poisson distribution such that $P(X = 1) = P(X = 2)$, find $P(X = 4)$.

3.2.2. The mgf of a random variable X is $e^{4(e^t - 1)}$. Show that $P(\mu - 2\sigma < X < \mu + 2\sigma) = 0.931$.

3.2.3. In a lengthy manuscript, it is discovered that only 13.5 percent of the pages contain no typing errors. If we assume that the number of errors per page is a random variable with a Poisson distribution, find the percentage of pages that have exactly one error.

3.2.4. Let the pmf $p(x)$ be positive on and only on the nonnegative integers. Given that $p(x) = (4/x)p(x-1)$, $x = 1, 2, 3, \dots$, find the formula for $p(x)$.

Hint: Note that $p(1) = 4p(0)$, $p(2) = (4^2/2!)p(0)$, and so on. That is, find each $p(x)$ in terms of $p(0)$ and then determine $p(0)$ from

$$1 = p(0) + p(1) + p(2) + \dots$$

3.2.5. Let X have a Poisson distribution with $\mu = 100$. Use Chebyshev's inequality to determine a lower bound for $P(75 < X < 125)$. Next, calculate the probability using R. Is the approximation by Chebyshev's inequality accurate?

3.2.6. The following R code segment computes a page of plots for Poisson pmfs with means 2, 4, 6, ..., 18. Run this code and comment on the shapes and modes of the distributions.

```
par(mfrow=c(3,3)); x= 0:35; lam=seq(2,18,2);
for(y in lam){plot(dpois(x,y)^x); title(paste("Mean is ",y))}
```

3.2.7. By Exercise 3.2.6 it seems that the Poisson pmf peaks at its mean λ . Show that this is the case by solving the inequalities $[p(x + 1)/p(x)] > 1$ and $[p(x + 1)/p(x)] < 1$, where $p(x)$ is the pmf of a Poisson distribution with parameter λ .

3.2.8. Using the computer, obtain an overlay plot of the pmfs of the following two distributions:

- (a) Poisson distribution with $\lambda = 2$.
- (b) Binomial distribution with $n = 100$ and $p = 0.02$.

Why would these distributions be approximately the same? Discuss.

3.2.9. Continuing with Exercise 3.2.8, make a page of four overlay plots for the following 4 Poisson and binomial combinations: $\lambda = 2, p = 0.02$; $\lambda = 10, p = 0.10$; $\lambda = 30, p = 0.30$; $\lambda = 50, p = 0.50$. Use $n = 100$ in each situation. Plot the subset of the binomial range that is between $np \pm \sqrt{np(1 - p)}$. For each situation, comment on the goodness of the Poisson approximation to the binomial.

3.2.10. The approximation discussed in Exercise 3.2.8 can be made precise in the following way. Suppose X_n is binomial with the parameters n and $p = \lambda/n$, for a given $\lambda > 0$. Let Y be Poisson with mean λ . Show that $P(X_n = k) \rightarrow P(Y = k)$, as $n \rightarrow \infty$, for an arbitrary but fixed value of k .

Hint: First show that:

$$P(X_n = k) = \frac{\lambda^k}{k!} \left[\frac{n(n-1)\cdots(n-k+1)}{n^k} \left(1 - \frac{\lambda}{n}\right)^{-k} \right] \left(1 - \frac{\lambda}{n}\right)^n.$$

3.2.11. Let the number of chocolate chips in a certain type of cookie have a Poisson distribution. We want the probability that a cookie of this type contains at least two chocolate chips to be greater than 0.99. Find the smallest value of the mean that the distribution can take.

3.2.12. Compute the measures of skewness and kurtosis of the Poisson distribution with mean μ .

3.2.13. On the average, a grocer sells three of a certain article per week. How many of these should he have in stock so that the chance of his running out within a week is less than 0.01? Assume a Poisson distribution.

3.2.14. Let X have a Poisson distribution. If $P(X = 1) = P(X = 3)$, find the mode of the distribution.

3.2.15. Let X have a Poisson distribution with mean 1. Compute, if it exists, the expected value $E(X!)$.

3.2.16. Let X and Y have the joint pmf $p(x, y) = e^{-2}/[x!(y-x)!]$, $y = 0, 1, 2, \dots$, $x = 0, 1, \dots, y$, zero elsewhere.

(a) Find the mgf $M(t_1, t_2)$ of this joint distribution.

(b) Compute the means, the variances, and the correlation coefficient of X and Y .

(c) Determine the conditional mean $E(X|y)$.

Hint: Note that

$$\sum_{x=0}^y [\exp(t_1 x)] y! / [x!(y-x)!] = [1 + \exp(t_1)]^y.$$

Why?

3.2.17. Let X_1 and X_2 be two independent random variables. Suppose that X_1 and $Y = X_1 + X_2$ have Poisson distributions with means μ_1 and $\mu > \mu_1$, respectively. Find the distribution of X_2 .

3.3 The Γ , χ^2 , and β Distributions

In this section we introduce the continuous gamma Γ -distribution and several associated distributions. The support for the Γ -distribution is the set of positive real numbers. This distribution and its associated distributions are rich in applications in all areas of science and business. These applications include their use in modeling lifetimes, failure times, service times, and waiting times.

The definition of the Γ -distribution requires the Γ function from calculus. It is proved in calculus that the integral

$$\int_0^\infty y^{\alpha-1} e^{-y} dy$$

exists for $\alpha > 0$ and that the value of the integral is a positive number. The integral is called the **gamma function** of α , and we write

$$\Gamma(\alpha) = \int_0^\infty y^{\alpha-1} e^{-y} dy.$$

If $\alpha = 1$, clearly

$$\Gamma(1) = \int_0^\infty e^{-y} dy = 1.$$

If $\alpha > 1$, an integration by parts shows that

$$\Gamma(\alpha) = (\alpha - 1) \int_0^\infty y^{\alpha-2} e^{-y} dy = (\alpha - 1)\Gamma(\alpha - 1). \quad (3.3.1)$$

Accordingly, if α is a positive integer greater than 1,

$$\Gamma(\alpha) = (\alpha - 1)(\alpha - 2) \cdots (3)(2)(1)\Gamma(1) = (\alpha - 1)!.$$

Since $\Gamma(1) = 1$, this suggests we take $0! = 1$, as we have done. The Γ function is sometimes called the factorial function.

We say that the continuous random variable X has a Γ -distribution with parameters $\alpha > 0$ and $\beta > 0$, if its pdf is

$$f(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.2)$$

In which case, we often write that X has $\Gamma(\alpha, \beta)$ distribution.

To verify that $f(x)$ is a pdf, note first that $f(x) > 0$, for all $x > 0$. To show that it integrates to 1 over its support, we use the change-of-variable $z = x/\beta$, $dz = (1/\beta)dx$ in the following derivation:

$$\begin{aligned} \int_0^\infty \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx &= \frac{1}{\Gamma(\alpha)\beta^\alpha} \int_0^\infty (\beta z)^{\alpha-1} e^{-z} \beta dz \\ &= \frac{1}{\Gamma(\alpha)\beta^\alpha} \beta^\alpha \Gamma(\alpha) = 1; \end{aligned}$$

hence, $f(x)$ is a pdf. This change-of-variable used is worth remembering. We use a similar change-of-variable in the following derivation of X 's mgf:

$$\begin{aligned} M(t) &= \int_0^\infty e^{tx} \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta} dx \\ &= \int_0^\infty \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x(1-\beta t)/\beta} dx. \end{aligned}$$

Next, use the change-of-variable $y = x(1 - \beta t)/\beta$, $t < 1/\beta$, or $x = \beta y/(1 - \beta t)$, to obtain

$$M(t) = \int_0^\infty \frac{\beta/(1 - \beta t)}{\Gamma(\alpha)\beta^\alpha} \left(\frac{\beta y}{1 - \beta t} \right)^{\alpha-1} e^{-y} dy.$$

That is,

$$\begin{aligned} M(t) &= \left(\frac{1}{1 - \beta t} \right)^\alpha \int_0^\infty \frac{1}{\Gamma(\alpha)} y^{\alpha-1} e^{-y} dy \\ &= \frac{1}{(1 - \beta t)^\alpha}, \quad t < \frac{1}{\beta}. \end{aligned}$$

Now

$$M'(t) = (-\alpha)(1 - \beta t)^{-\alpha-1}(-\beta)$$

and

$$M''(t) = (-\alpha)(-\alpha - 1)(1 - \beta t)^{-\alpha-2}(-\beta)^2.$$

Hence, for a gamma distribution, we have

$$\mu = M'(0) = \alpha\beta$$

and

$$\sigma^2 = M''(0) - \mu^2 = \alpha(\alpha + 1)\beta^2 - \alpha^2\beta^2 = \alpha\beta^2.$$

Suppose X has a $\Gamma(\alpha, \beta)$ distribution. To calculate probabilities for this distribution in R, let $a = \alpha$ and $b = \beta$. Then the command `pgamma(x, shape=a, scale=b)` returns $P(X \leq x)$, while the value of the pdf of X at x is returned by the command `dgamma(x, shape=a, scale=b)`.

Example 3.3.1. Let X be the lifetime in hours of a certain battery used under extremely cold conditions. Suppose X has a $\Gamma(5, 4)$ distribution. Then the mean lifetime of the battery is 20 hours with standard deviation $\sqrt{5 \times 16} = 8.94$ hours. The probability that battery lasts at least 50 hours is `1-pgamma(50, shape=5, scale=4) = 0.0053`. The median lifetime of the battery is `qgamma(.5, shape=5, scale=4) = 18.68` hours. The probability that the lifetime is within one standard deviation of its mean lifetime is

```
pgamma(20+8.94, shape=5, scale=4)-pgamma(20-8.94, shape=5, scale=4)=.700.
```

Finally, this line of R code presents a plot of the pdf:

```
x=seq(.1,50,.1); plot(dgamma(x,shape=5,scale=4)~x).
```

On this plot, the reader should locate the above probabilities and the mean and median lifetimes of the battery. ■

The main reason for the appeal of the Γ -distribution in applications is the variety of shapes of the distribution for different values of α and β . This is apparent in Figure 3.3.1 which depicts six Γ -pdfs.⁴

Suppose X denotes the failure time of a device with pdf $f(x)$ and cdf $F(x)$. In practice, the pdf of X is often unknown. If a large sample of failure times of these devices is at hand then estimates of the pdf can be obtained as discussed in Chapter 4. Another function that helps in identifying the pdf of X is the *hazard function* of X . Let x be in the support of X . Suppose the device has not failed at time x , i.e., $X > x$. What is the probability that the device fails in the next instance? We answer this question in terms of the rate of failure at x , which is:

$$\begin{aligned} r(x) &= \lim_{\Delta \rightarrow 0} \frac{P(x \leq X < x + \Delta | X \geq x)}{\Delta} = \frac{1}{1 - F(x)} \lim_{\Delta \rightarrow 0} \frac{P(x \leq X < x + \Delta)}{\Delta} \\ &= \frac{f(x)}{1 - F(x)}. \end{aligned} \tag{3.3.3}$$

The rate of failure at time x , $r(x)$, is defined as the **hazard function** of X at x .

⁴The R function for these plots is `newfigc3s3.1.R`, at the site listed in the Preface.

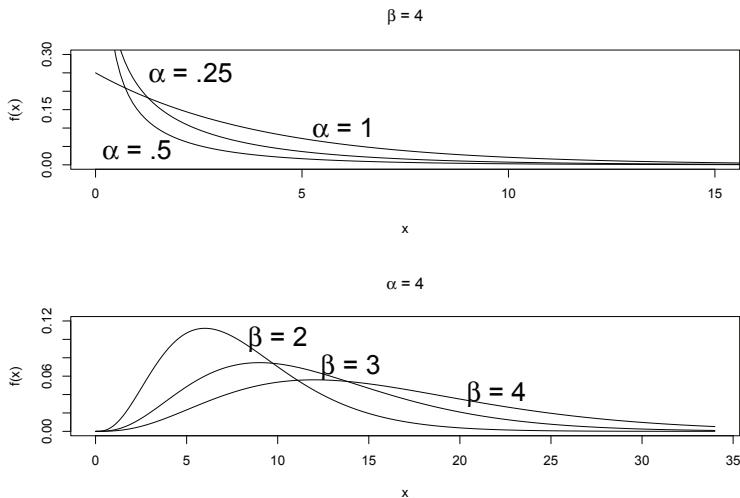

Figure 3.3.1: Several gamma densities

Note that the hazard function $r(x)$ satisfies $-(d/dx) \log[1 - F(x)]$; that is,

$$1 - F(x) = e^{-\int r(x) dx + c}, \quad (3.3.4)$$

for a constant c . When the support of X is $(0, \infty)$, $F(0) = 0$ serves as a boundary condition to solve for c . In practice, often the scientist can describe the hazard rate and, hence, $F(x)$ can be determined from expression (3.3.4). For example, suppose the hazard rate of X is constant; i.e., $r(x) = 1/\beta$ for some $\beta > 0$. Then

$$1 - F(x) = e^{-\int (1/\beta) dx + c} = e^{-x/\beta} e^c.$$

Since $F(0) = 0$, $e^c = 1$. So the pdf of X is

$$f(x) = \begin{cases} \frac{1}{\beta} e^{-x/\beta} & x > 0 \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.5)$$

Of course, this is a $\Gamma(1, \beta)$ distribution, but it is also called the **exponential distribution** with parameter $1/\beta$. An important property of this distribution is given in Exercise 3.3.25.

Using R, hazard functions can be quickly plotted. Here is the code for an overlay plot of the hazard functions of the exponential distribution with $\beta = 8$ and the $\Gamma(4, 2)$ -distribution.

```
x=seq(.1,15,.1); t=dgamma(x,shape=4,scale=2)
b=(1-pgamma(x,shape=4,scale=2));y1=t/b;plot(y1~x);abline(h=1/8)
```

Note that the hazard function of this Γ -distribution is an increasing function of x ; i.e., the rate of failure increases as time progresses. Other examples of hazard functions are given in Exercise 3.3.26.

One of the most important properties of the gamma distribution is its additive property.

Theorem 3.3.1. *Let X_1, \dots, X_n be independent random variables. Suppose, for $i = 1, \dots, n$, that X_i has a $\Gamma(\alpha_i, \beta)$ distribution. Let $Y = \sum_{i=1}^n X_i$. Then Y has a $\Gamma(\sum_{i=1}^n \alpha_i, \beta)$ distribution.*

Proof: Using the assumed independence and the mgf of a gamma distribution, we have by Theorem 2.6.1 that for $t < 1/\beta$,

$$M_Y(t) = \prod_{i=1}^n (1 - \beta t)^{-\alpha_i} = (1 - \beta t)^{-\sum_{i=1}^n \alpha_i},$$

which is the mgf of a $\Gamma(\sum_{i=1}^n \alpha_i, \beta)$ distribution. ■

Γ -distributions naturally occur in the Poisson process, also.

Remark 3.3.1 (Poisson Processes). For $t > 0$, let X_t denote the number of events of interest that occur in the interval $(0, t]$. Assume X_t satisfies the three assumptions of a Poisson process. Let k be a fixed positive integer and define the continuous random variable W_k to be the waiting time until the k th event occurs. Then the range of W_k is $(0, \infty)$. Note that for $w > 0$, $W_k > w$ if and only if $X_w \leq k - 1$. Hence,

$$P(W_k > w) = P(X_w \leq k - 1) = \sum_{x=0}^{k-1} P(X_w = x) = \sum_{x=0}^{k-1} \frac{(\lambda w)^x e^{-\lambda w}}{x!}.$$

In Exercise 3.3.5, the reader is asked to prove that

$$\int_{\lambda w}^{\infty} \frac{z^{k-1} e^{-z}}{(k-1)!} dz = \sum_{x=0}^{k-1} \frac{(\lambda w)^x e^{-\lambda w}}{x!}.$$

Accepting this result, we have, for $w > 0$, that the cdf of W_k satisfies

$$F_{W_k}(w) = 1 - \int_{\lambda w}^{\infty} \frac{z^{k-1} e^{-z}}{\Gamma(k)} dz = \int_0^{\lambda w} \frac{z^{k-1} e^{-z}}{\Gamma(k)} dz,$$

and for $w \leq 0$, $F_{W_k}(w) = 0$. If we change the variable of integration in the integral that defines $F_{W_k}(w)$ by writing $z = \lambda y$, then

$$F_{W_k}(w) = \int_0^w \frac{\lambda^k y^{k-1} e^{-\lambda y}}{\Gamma(k)} dy, \quad w > 0,$$

and $F_{W_k}(w) = 0$ for $w \leq 0$. Accordingly, the pdf of W_k is

$$f_{W_k}(w) = F'_W(w) = \begin{cases} \frac{\lambda^k w^{k-1} e^{-\lambda w}}{\Gamma(k)} & 0 < w < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

That is, the waiting time until the k th event, W_k , has the gamma distribution with $\alpha = k$ and $\beta = 1/\lambda$. Let T_1 be the waiting time until the first event occurs, i.e., $k = 1$. Then the pdf of T_1 is

$$f_{T_1}(w) = \begin{cases} \lambda e^{-\lambda w} & 0 < w < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.6)$$

Hence, T_1 has the $\Gamma(1, 1/\lambda)$ -distribution. The mean of $T_1 = 1/\lambda$, while the mean of X_1 is λ . Thus, we expect λ events to occur in a unit of time and we expect the first event to occur at time $1/\lambda$.

Continuing in this way, for $i \geq 1$, let T_i denote the interarrival time of the i th event; i.e., T_i is the time between the occurrence of event $(i - 1)$ and event i . As shown T_1 has the $\Gamma(1, 1/\lambda)$. Note that Axioms (1) and (2) of the Poisson process only depend on λ and the length of the interval; in particular, they do not depend on the endpoints of the interval. Further, occurrences in nonoverlapping intervals are independent of one another. Hence, using the same reasoning as above, T_j , $j \geq 2$, also has the $\Gamma(1, 1/\lambda)$ -distribution. Furthermore, T_1, T_2, T_3, \dots are independent. Note the waiting time until the k th event satisfies $W_k = T_1 + \dots + T_k$. Thus by Theorem 3.3.1, W_k has a $\Gamma(k, 1/\lambda)$ distribution, confirming the derivation above. Although this discussion has been intuitive, it can be made rigorous; see, for example, Parzen (1962). ■

3.3.1 The χ^2 -Distribution

Let us now consider a special case of the gamma distribution in which $\alpha = r/2$, where r is a positive integer, and $\beta = 2$. A random variable X of the continuous type that has the pdf

$$f(x) = \begin{cases} \frac{1}{\Gamma(r/2)2^{r/2}}x^{r/2-1}e^{-x/2} & 0 < x < \infty \\ 0 & \text{elsewhere,} \end{cases} \quad (3.3.7)$$

and the mgf

$$M(t) = (1 - 2t)^{-r/2}, \quad t < \frac{1}{2},$$

is said to have a **chi-square distribution** (χ^2 -distribution), and any $f(x)$ of this form is called a **chi-square pdf**. The mean and the variance of a chi-square distribution are $\mu = \alpha\beta = (r/2)2 = r$ and $\sigma^2 = \alpha\beta^2 = (r/2)2^2 = 2r$, respectively. We call the parameter r the number of degrees of freedom of the chi-square distribution (or of the chi-square pdf). Because the chi-square distribution has an important role in statistics and occurs so frequently, we write, for brevity, that X is $\chi^2(r)$ to mean that the random variable X has a chi-square distribution with r degrees of freedom. The R function `pchisq(x, r)` returns $P(X \leq x)$ and the command `dchisq(x, r)` returns the value of the pdf of X at x when X has a chi-squared distribution with r degrees of freedom.

Example 3.3.2. Suppose X has a χ^2 -distribution with 10 degrees of freedom. Then the mean of X is 10 and its standard deviation is $\sqrt{20} = 4.47$. Using R, its median and quartiles are `qchisq(c(.25, .5, .75), 10) = (6.74, 9.34, 12.55)`. The following

command plots the density function over the interval $(0, 24)$:

```
x=seq(0,24,.1);plot(dchisq(x,10)^x).
```

Compute this line of code and locate the mean, quartiles, and median of X on the plot. ■

Example 3.3.3. The quantiles of the χ^2 -distribution are frequently used in statistics. Before the advent of modern computation, tables of these quantiles were compiled. Table I in Appendix D offers a typical χ^2 -table of the quantiles for the probabilities 0.01, 0.025, 0.05, 0.1, 0.9, 0.95, 0.975, 0.99 and degrees of freedom 1, 2, ..., 30. As discussed, the R function `qchisq` easily computes these quantiles. Actually, the following two lines of R code performs the computation of Table I.

```
rs=1:30; ps=c(.01,.025,.05,.1,.9,.95,.975,.99);
for(r in rs){print(c(r,round(qchisq(ps,r),digits=3)))}
```

Note that the code rounds the critical values to 3 places. ■

The following result is used several times in the sequel; hence, we record it as a theorem.

Theorem 3.3.2. Let X have a $\chi^2(r)$ distribution. If $k > -r/2$, then $E(X^k)$ exists and it is given by

$$E(X^k) = \frac{2^k \Gamma\left(\frac{r}{2} + k\right)}{\Gamma\left(\frac{r}{2}\right)} , \quad \text{if } k > -r/2. \quad (3.3.8)$$

Proof: Note that

$$E(X^k) = \int_0^\infty \frac{1}{\Gamma\left(\frac{r}{2}\right) 2^{r/2}} x^{(r/2)+k-1} e^{-x/2} dx.$$

Make the change of variable $u = x/2$ in the above integral. This results in

$$E(X^k) = \int_0^\infty \frac{1}{\Gamma\left(\frac{r}{2}\right) 2^{(r/2)-1}} 2^{(r/2)+k-1} u^{(r/2)+k-1} e^{-u} du.$$

This simplifies to the desired result provided that $k > -(r/2)$. ■

Notice that if k is a nonnegative integer, then $k > -(r/2)$ is always true. Hence, all moments of a χ^2 distribution exist and the k th moment is given by (3.3.8).

Example 3.3.4. Let X have a gamma distribution with $\alpha = r/2$, where r is a positive integer, and $\beta > 0$. Define the random variable $Y = 2X/\beta$. We seek the pdf of Y . Now the mgf of Y is

$$\begin{aligned} M_Y(t) &= E(e^{tY}) = E\left[e^{(2t/\beta)X}\right] \\ &= \left[1 - \frac{2t}{\beta}\right]^{-r/2} = [1 - 2t]^{-r/2}, \end{aligned}$$

which is the mgf of a χ^2 -distribution with r degrees of freedom. That is, Y is $\chi^2(r)$.

■

Because the χ^2 -distributions are a subfamily of the Γ -distributions, the additivity property for Γ -distributions given by Theorem 3.3.1 holds for χ^2 -distributions, also. Since we often make use of this property, we state it as a corollary for easy reference.

Corollary 3.3.1. *Let X_1, \dots, X_n be independent random variables. Suppose, for $i = 1, \dots, n$, that X_i has a $\chi^2(r_i)$ distribution. Let $Y = \sum_{i=1}^n X_i$. Then Y has a $\chi^2(\sum_{i=1}^n r_i)$ distribution.*

3.3.2 The β -Distribution

As we have discussed, in terms of modeling, the Γ -distributions offer a wide variety of shapes for skewed distributions with support $(0, \infty)$. In the exercises and later chapters, we offer other such families of distributions. How about continuous distributions whose support is a bounded interval in R ? For example suppose the support of X is (a, b) where $-\infty < a < b < \infty$ and a and b are known. Without loss of generality, for discussion, we can assume that $a = 0$ and $b = 1$, since, if not, we could consider the random variable $Y = (X - a)/(b - a)$. In this section, we discuss the **β -distribution** whose family offers a wide variety of shapes for distributions with support on bounded intervals.

One way of defining the β -family of distributions is to derive it from a pair of independent Γ random variables. Let X_1 and X_2 be two independent random variables that have Γ distributions and the joint pdf

$$h(x_1, x_2) = \frac{1}{\Gamma(\alpha)\Gamma(\beta)} x_1^{\alpha-1} x_2^{\beta-1} e^{-x_1-x_2}, \quad 0 < x_1 < \infty, \quad 0 < x_2 < \infty,$$

zero elsewhere, where $\alpha > 0$, $\beta > 0$. Let $Y_1 = X_1 + X_2$ and $Y_2 = X_1/(X_1 + X_2)$. We next show that Y_1 and Y_2 are independent.

The space \mathcal{S} is, exclusive of the points on the coordinate axes, the first quadrant of the x_1, x_2 -plane. Now

$$\begin{aligned} y_1 &= u_1(x_1, x_2) = x_1 + x_2 \\ y_2 &= u_2(x_1, x_2) = \frac{x_1}{x_1 + x_2} \end{aligned}$$

may be written $x_1 = y_1 y_2$, $x_2 = y_1(1 - y_2)$, so

$$J = \begin{vmatrix} y_2 & y_1 \\ 1 - y_2 & -y_1 \end{vmatrix} = -y_1 \not\equiv 0.$$

The transformation is one-to-one, and it maps \mathcal{S} onto $\mathcal{T} = \{(y_1, y_2) : 0 < y_1 < \infty, 0 < y_2 < 1\}$ in the $y_1 y_2$ -plane. The joint pdf of Y_1 and Y_2 on its support is

$$\begin{aligned} g(y_1, y_2) &= (y_1) \frac{1}{\Gamma(\alpha)\Gamma(\beta)} (y_1 y_2)^{\alpha-1} [y_1(1 - y_2)]^{\beta-1} e^{-y_1} \\ &= \begin{cases} \frac{y_2^{\alpha-1}(1-y_2)^{\beta-1}}{\Gamma(\alpha)\Gamma(\beta)} y_1^{\alpha+\beta-1} e^{-y_1} & 0 < y_1 < \infty, \quad 0 < y_2 < 1 \\ 0 & \text{elsewhere.} \end{cases} \end{aligned}$$

In accordance with Theorem 2.4.1 the random variables are independent. The marginal pdf of Y_2 is

$$\begin{aligned} g_2(y_2) &= \frac{y_2^{\alpha-1}(1-y_2)^{\beta-1}}{\Gamma(\alpha)\Gamma(\beta)} \int_0^\infty y_1^{\alpha+\beta-1} e^{-y_1} dy_1 \\ &= \begin{cases} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} y_2^{\alpha-1}(1-y_2)^{\beta-1} & 0 < y_2 < 1 \\ 0 & \text{elsewhere.} \end{cases} \end{aligned} \quad (3.3.9)$$

This pdf is that of the **beta distribution** with parameters α and β . Since $g(y_1, y_2) \equiv g_1(y_1)g_2(y_2)$, it must be that the pdf of Y_1 is

$$g_1(y_1) = \begin{cases} \frac{1}{\Gamma(\alpha+\beta)} y_1^{\alpha+\beta-1} e^{-y_1} & 0 < y_1 < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

which is that of a gamma distribution with parameter values of $\alpha + \beta$ and 1.

It is an easy exercise to show that the mean and the variance of Y_2 , which has a beta distribution with parameters α and β , are, respectively,

$$\mu = \frac{\alpha}{\alpha + \beta}, \quad \sigma^2 = \frac{\alpha\beta}{(\alpha + \beta + 1)(\alpha + \beta)^2}.$$

The package R calculates probabilities for the beta distribution. If X has a beta distribution with parameters $\alpha = a$ and $\beta = b$, then the command `pbeta(x,a,b)` returns $P(X \leq x)$ and the command `dbeta(x,a,b)` returns the value of the pdf of X at x .

Example 3.3.5 (Shapes of β -Distributions). The following 3 lines of R code⁵, will obtain a 4×4 page of plots of β pdfs for all combinations of integer values of α and β between 2 and 5. Those distributions on the main diagonal of the page of plots are symmetric, those below the main diagonal are left-skewed, and those above the main diagonal are right-skewed.

```
par(mfrow=c(4,4)); r1=2:5; r2=2:5;x=seq(.01,.99,.01)
for(a in r1){for(b in r2){plot(dbeta(x,a,b)^x);
title(paste("alpha = ",a,"beta = ",b))}}
```

Note that if $\alpha = \beta = 1$, then the β -distribution is the uniform distribution with support $(0, 1)$.

We close this section with another example of a random variable whose distribution is derived from a transformation of gamma random variables.

Example 3.3.6 (Dirichlet Distribution). Let X_1, X_2, \dots, X_{k+1} be independent random variables, each having a gamma distribution with $\beta = 1$. The joint pdf of these variables may be written as

$$h(x_1, x_2, \dots, x_{k+1}) = \begin{cases} \prod_{i=1}^{k+1} \frac{1}{\Gamma(\alpha_i)} x_i^{\alpha_i-1} e^{-x_i} & 0 < x_i < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

⁵Download the R function `betaplts` at the site listed in the Preface.

Let

$$Y_i = \frac{X_i}{X_1 + X_2 + \cdots + X_{k+1}}, \quad i = 1, 2, \dots, k,$$

and $Y_{k+1} = X_1 + X_2 + \cdots + X_{k+1}$ denote $k+1$ new random variables. The associated transformation maps $\mathcal{A} = \{(x_1, \dots, x_{k+1}) : 0 < x_i < \infty, i = 1, \dots, k+1\}$ onto the space:

$$\mathcal{B} = \{(y_1, \dots, y_k, y_{k+1}) : 0 < y_i, i = 1, \dots, k, y_1 + \cdots + y_k < 1, 0 < y_{k+1} < \infty\}.$$

The single-valued inverse functions are $x_1 = y_1 y_{k+1}, \dots, x_k = y_k y_{k+1}, x_{k+1} = y_{k+1}(1 - y_1 - \cdots - y_k)$, so that the Jacobian is

$$J = \begin{vmatrix} y_{k+1} & 0 & \cdots & 0 & y_1 \\ 0 & y_{k+1} & \cdots & 0 & y_2 \\ \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & \cdots & y_{k+1} & y_k \\ -y_{k+1} & -y_{k+1} & \cdots & -y_{k+1} & (1 - y_1 - \cdots - y_k) \end{vmatrix} = y_{k+1}^k.$$

Hence the joint pdf of Y_1, \dots, Y_k, Y_{k+1} is given by

$$\frac{y_{k+1}^{\alpha_1+\cdots+\alpha_{k+1}-1} y_1^{\alpha_1-1} \cdots y_k^{\alpha_k-1} (1 - y_1 - \cdots - y_k)^{\alpha_{k+1}-1} e^{-y_{k+1}}}{\Gamma(\alpha_1) \cdots \Gamma(\alpha_k) \Gamma(\alpha_{k+1})},$$

provided that $(y_1, \dots, y_k, y_{k+1}) \in \mathcal{B}$ and is equal to zero elsewhere. By integrating out y_{k+1} , the joint pdf of Y_1, \dots, Y_k is seen to be

$$g(y_1, \dots, y_k) = \frac{\Gamma(\alpha_1 + \cdots + \alpha_{k+1})}{\Gamma(\alpha_1) \cdots \Gamma(\alpha_{k+1})} y_1^{\alpha_1-1} \cdots y_k^{\alpha_k-1} (1 - y_1 - \cdots - y_k)^{\alpha_{k+1}-1}, \quad (3.3.10)$$

when $0 < y_i, i = 1, \dots, k, y_1 + \cdots + y_k < 1$, while the function g is equal to zero elsewhere. Random variables Y_1, \dots, Y_k that have a joint pdf of this form are said to have a **Dirichlet pdf**. It is seen, in the special case of $k = 1$, that the Dirichlet pdf becomes a beta pdf. Moreover, it is also clear from the joint pdf of Y_1, \dots, Y_k, Y_{k+1} that Y_{k+1} has a gamma distribution with parameters $\alpha_1 + \cdots + \alpha_k + \alpha_{k+1}$ and $\beta = 1$ and that Y_{k+1} is independent of Y_1, Y_2, \dots, Y_k . ■

EXERCISES

3.3.1. Suppose $(1 - 2t)^{-6}$, $t < \frac{1}{2}$ is the mgf of the random variable X .

(a) Use R to compute $P(X < 5.23)$.

(b) Find the mean μ and variance σ^2 of X . Use R to compute $P(|X - \mu| < 2\sigma)$.

3.3.2. If X is $\chi^2(5)$, determine the constants c and d so that $P(c < X < d) = 0.95$ and $P(X < c) = 0.025$.

3.3.3. Suppose the lifetime in months of an engine, working under hazardous conditions, has a Γ distribution with a mean of 10 months and a variance of 20 months squared.

- (a) Determine the median lifetime of an engine.
- (b) Suppose such an engine is termed successful if its lifetime exceeds 15 months. In a sample of 10 engines, determine the probability of at least 3 successful engines.

3.3.4. Let X be a random variable such that $E(X^m) = (m+1)!2^m$, $m = 1, 2, 3, \dots$. Determine the mgf and the distribution of X .

Hint: Write out the Taylor series⁶ of the mgf.

3.3.5. Show that

$$\int_{\mu}^{\infty} \frac{1}{\Gamma(k)} z^{k-1} e^{-z} dz = \sum_{x=0}^{k-1} \frac{\mu^x e^{-\mu}}{x!}, \quad k = 1, 2, 3, \dots$$

This demonstrates the relationship between the cdfs of the gamma and Poisson distributions.

Hint: Either integrate by parts $k-1$ times or obtain the “antiderivative” by showing that

$$\frac{d}{dz} \left[-e^{-z} \sum_{j=0}^{k-1} \frac{\Gamma(k)}{(k-j-1)!} z^{k-j-1} \right] = z^{k-1} e^{-z}.$$

3.3.6. Let X_1 , X_2 , and X_3 be iid random variables, each with pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere.

- (a) Find the distribution of $Y = \min(X_1, X_2, X_3)$.

Hint: $P(Y \leq y) = 1 - P(Y > y) = 1 - P(X_i > y, i = 1, 2, 3)$.

- (b) Find the distribution of $Y = \max(X_1, X_2, X_3)$.

3.3.7. Let X have a gamma distribution with pdf

$$f(x) = \frac{1}{\beta^2} x e^{-x/\beta}, \quad 0 < x < \infty,$$

zero elsewhere. If $x = 2$ is the unique mode of the distribution, find the parameter β and $P(X < 9.49)$.

3.3.8. Compute the measures of skewness and kurtosis of a gamma distribution that has parameters α and β .

3.3.9. Let X have a gamma distribution with parameters α and β . Show that $P(X \geq 2\alpha\beta) \leq (2/e)^{\alpha}$.

Hint: Use the result of Exercise 1.10.5.

⁶See, for example, the discussion on Taylor series in *Mathematical Comments* referenced in the Preface.

3.3.10. Give a reasonable definition of a chi-square distribution with zero degrees of freedom.

Hint: Work with the mgf of a distribution that is $\chi^2(r)$ and let $r = 0$.

3.3.11. Using the computer, obtain plots of the pdfs of chi-squared distributions with degrees of freedom $r = 1, 2, 5, 10, 20$. Comment on the plots.

3.3.12. Using the computer, plot the cdf of a $\Gamma(5, 4)$ distribution and use it to guess the median. Confirm it with a computer command that returns the median [In R, use the command `qgamma(.5, shape=5, scale=4)`].

3.3.13. Using the computer, obtain plots of beta pdfs for $\alpha = 1, 5, 10$ and $\beta = 1, 2, 5, 10, 20$.

3.3.14. In a warehouse of parts for a large mill, the average time between requests for parts is about 10 minutes.

- (a) Find the probability that in an hour there will be at least 10 requests for parts.
- (b) Find the probability that the 10th request in the morning requires at least 2 hours of waiting time.

3.3.15. Let X have a Poisson distribution with parameter m . If m is an experimental value of a random variable having a gamma distribution with $\alpha = 2$ and $\beta = 1$, compute $P(X = 0, 1, 2)$.

Hint: Find an expression that represents the joint distribution of X and m . Then integrate out m to find the marginal distribution of X .

3.3.16. Let X have the uniform distribution with pdf $f(x) = 1$, $0 < x < 1$, zero elsewhere. Find the cdf of $Y = -2 \log X$. What is the pdf of Y ?

3.3.17. Find the uniform distribution of the continuous type on the interval (b, c) that has the same mean and the same variance as those of a chi-square distribution with 8 degrees of freedom. That is, find b and c .

3.3.18. Find the mean and variance of the β distribution.

Hint: From the pdf, we know that

$$\int_0^1 y^{\alpha-1} (1-y)^{\beta-1} dy = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$$

for all $\alpha > 0$, $\beta > 0$.

3.3.19. Determine the constant c in each of the following so that each $f(x)$ is a β pdf:

- (a) $f(x) = cx(1-x)^3$, $0 < x < 1$, zero elsewhere.
- (b) $f(x) = cx^4(1-x)^5$, $0 < x < 1$, zero elsewhere.
- (c) $f(x) = cx^2(1-x)^8$, $0 < x < 1$, zero elsewhere.

3.3.20. Determine the constant c so that $f(x) = cx(3-x)^4$, $0 < x < 3$, zero elsewhere, is a pdf.

3.3.21. Show that the graph of the β pdf is symmetric about the vertical line through $x = \frac{1}{2}$ if $\alpha = \beta$.

3.3.22. Show, for $k = 1, 2, \dots, n$, that

$$\int_p^1 \frac{n!}{(k-1)!(n-k)!} z^{k-1} (1-z)^{n-k} dz = \sum_{x=0}^{k-1} \binom{n}{x} p^x (1-p)^{n-x}.$$

This demonstrates the relationship between the cdfs of the β and binomial distributions.

3.3.23. Let X_1 and X_2 be independent random variables. Let X_1 and $Y = X_1 + X_2$ have chi-square distributions with r_1 and r degrees of freedom, respectively. Here $r_1 < r$. Show that X_2 has a chi-square distribution with $r - r_1$ degrees of freedom.
Hint: Write $M(t) = E(e^{t(X_1+X_2)})$ and make use of the independence of X_1 and X_2 .

3.3.24. Let X_1, X_2 be two independent random variables having gamma distributions with parameters $\alpha_1 = 3$, $\beta_1 = 3$ and $\alpha_2 = 5$, $\beta_2 = 1$, respectively.

(a) Find the mgf of $Y = 2X_1 + 6X_2$.

(b) What is the distribution of Y ?

3.3.25. Let X have an exponential distribution.

(a) For $x > 0$ and $y > 0$, show that

$$P(X > x + y | X > x) = P(X > y). \quad (3.3.11)$$

Hence, the exponential distribution has the **memoryless** property. Recall from Exercise 3.1.9 that the discrete geometric distribution has a similar property.

(b) Let $F(x)$ be the cdf of a continuous random variable Y . Assume that $F(0) = 0$ and $0 < F(y) < 1$ for $y > 0$. Suppose property (3.3.11) holds for Y . Show that $F_Y(y) = 1 - e^{-\lambda y}$ for $y > 0$.

Hint: Show that $g(y) = 1 - F_Y(y)$ satisfies the equation

$$g(y+z) = g(y)g(z),$$

3.3.26. Let X denote time until failure of a device and let $r(x)$ denote the hazard function of X .

(a) If $r(x) = cx^b$; where c and b are positive constants, show that X has a **Weibull** distribution; i.e.,

$$f(x) = \begin{cases} cx^b \exp\left\{-\frac{cx^{b+1}}{b+1}\right\} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.12)$$

- (b) If $r(x) = ce^{bx}$, where c and b are positive constants, show that X has a **Gompertz** cdf given by

$$F(x) = \begin{cases} 1 - \exp\left\{\frac{c}{b}(1 - e^{bx})\right\} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.13)$$

This is frequently used by actuaries as a distribution of the length of human life.

- (c) If $r(x) = bx$, linear hazard rate, show that the pdf of X is

$$f(x) = \begin{cases} bxe^{-bx^2/2} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.3.14)$$

This pdf is called the **Rayleigh** pdf.

3.3.27. Write an R function that returns the value $f(x)$ for a specified x when $f(x)$ is the Weibull pdf given in expression (3.3.12). Next write an R function that returns the associated hazard function $r(x)$. Obtain side-by-side plots of the pdf and hazard function for the three cases: $c = 5$ and $b = 0.5$; $c = 5$ and $b = 1.0$; and $c = 5$ and $b = 1.5$.

3.3.28. In Example 3.3.5, a page of plots of β pdfs was discussed. All of these pdfs are mound shaped. Obtain a page of plots for all combinations of α and β drawn from the set $\{.25, .75, 1, 1.25\}$. Comment on these shapes.

3.3.29. Let Y_1, \dots, Y_k have a Dirichlet distribution with parameters $\alpha_1, \dots, \alpha_k, \alpha_{k+1}$.

- (a) Show that Y_1 has a beta distribution with parameters $\alpha = \alpha_1$ and $\beta = \alpha_2 + \dots + \alpha_{k+1}$.
- (b) Show that $Y_1 + \dots + Y_r$, $r \leq k$, has a beta distribution with parameters $\alpha = \alpha_1 + \dots + \alpha_r$ and $\beta = \alpha_{r+1} + \dots + \alpha_{k+1}$.
- (c) Show that $Y_1 + Y_2$, $Y_3 + Y_4$, Y_5, \dots, Y_k , $k \geq 5$, have a Dirichlet distribution with parameters $\alpha_1 + \alpha_2$, $\alpha_3 + \alpha_4$, $\alpha_5, \dots, \alpha_k, \alpha_{k+1}$.

Hint: Recall the definition of Y_i in Example 3.3.6 and use the fact that the sum of several independent gamma variables with $\beta = 1$ is a gamma variable.

3.4 The Normal Distribution

Motivation for the normal distribution is found in the Central Limit Theorem, which is presented in Section 5.3. This theorem shows that normal distributions provide an important family of distributions for applications and for statistical inference, in general. We proceed by first introducing the standard normal distribution and through it the general normal distribution.

Consider the integral

$$I = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left(\frac{-z^2}{2}\right) dz. \quad (3.4.1)$$

This integral exists because the integrand is a positive continuous function that is bounded by an integrable function; that is,

$$0 < \exp\left(\frac{-z^2}{2}\right) < \exp(-|z| + 1), \quad -\infty < z < \infty,$$

and

$$\int_{-\infty}^{\infty} \exp(-|z| + 1) dz = 2e.$$

To evaluate the integral I , we note that $I > 0$ and that I^2 may be written

$$I^2 = \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \exp\left(-\frac{z^2 + w^2}{2}\right) dz dw.$$

This iterated integral can be evaluated by changing to polar coordinates. If we set $z = r \cos \theta$ and $w = r \sin \theta$, we have

$$\begin{aligned} I^2 &= \frac{1}{2\pi} \int_0^{2\pi} \int_0^{\infty} e^{-r^2/2} r dr d\theta \\ &= \frac{1}{2\pi} \int_0^{2\pi} d\theta = 1. \end{aligned}$$

Because the integrand of display (3.4.1) is positive on R and integrates to 1 over R , it is a pdf of a continuous random variable with support R . We denote this random variable by Z . In summary, Z has the pdf

$$f(z) = \frac{1}{\sqrt{2\pi}} \exp\left(\frac{-z^2}{2}\right), \quad -\infty < z < \infty. \quad (3.4.2)$$

For $t \in R$, the mgf of Z can be derived by a completion of a square as follows:

$$\begin{aligned} E[\exp\{tZ\}] &= \int_{-\infty}^{\infty} \exp\{tz\} \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}z^2\right\} dz \\ &= \exp\left\{\frac{1}{2}t^2\right\} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}(z-t)^2\right\} dz \\ &= \exp\left\{\frac{1}{2}t^2\right\} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}w^2\right\} dw, \end{aligned} \quad (3.4.3)$$

where for the last integral we made the one-to-one change of variable $w = z - t$. By the identity (3.4.2), the integral in expression (3.4.3) has value 1. Thus the mgf of Z is

$$M_Z(t) = \exp\left\{\frac{1}{2}t^2\right\}, \quad \text{for } -\infty < t < \infty. \quad (3.4.4)$$

The first two derivatives of $M_Z(t)$ are easily shown to be

$$\begin{aligned} M'_Z(t) &= t \exp\left\{\frac{1}{2}t^2\right\} \\ M''_Z(t) &= \exp\left\{\frac{1}{2}t^2\right\} + t^2 \exp\left\{\frac{1}{2}t^2\right\}. \end{aligned}$$

Upon evaluating these derivatives at $t = 0$, the mean and variance of Z are

$$E(Z) = 0 \text{ and } \text{Var}(Z) = 1. \quad (3.4.5)$$

Next, define the continuous random variable X by

$$X = bZ + a,$$

for $b > 0$. This is a one-to-one transformation. To derive the pdf of X , note that the inverse of the transformation and the Jacobian are $z = b^{-1}(x - a)$ and $J = b^{-1}$, respectively. Because $b > 0$, it follows from (3.4.2) that the pdf of X is

$$f_X(x) = \frac{1}{\sqrt{2\pi}b} \exp\left\{-\frac{1}{2}\left(\frac{x-a}{b}\right)^2\right\}, \quad -\infty < x < \infty.$$

By (3.4.5), we immediately have $E(X) = a$ and $\text{Var}(X) = b^2$. Hence, in the expression for the pdf of X , we can replace a by $\mu = E(X)$ and b^2 by $\sigma^2 = \text{Var}(X)$. We make this formal in the following:

Definition 3.4.1 (Normal Distribution). *We say a random variable X has a **normal distribution** if its pdf is*

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left\{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2\right\}, \quad \text{for } -\infty < x < \infty. \quad (3.4.6)$$

The parameters μ and σ^2 are the mean and variance of X , respectively. We often write that X has a $N(\mu, \sigma^2)$ distribution.

In this notation, the random variable Z with pdf (3.4.2) has a $N(0, 1)$ distribution. We call Z a **standard normal** random variable.

For the mgf of X , use the relationship $X = \sigma Z + \mu$ and the mgf for Z , (3.4.4), to obtain

$$\begin{aligned} E[\exp\{tX\}] &= E[\exp\{t(\sigma Z + \mu)\}] = \exp\{\mu t\} E[\exp\{t\sigma Z\}] \\ &= \exp\{\mu t\} \exp\left\{\frac{1}{2}\sigma^2 t^2\right\} = \exp\left\{\mu t + \frac{1}{2}\sigma^2 t^2\right\}, \end{aligned} \quad (3.4.7)$$

for $-\infty < t < \infty$.

We summarize the above discussion, by noting the relationship between Z and X :

$$X \text{ has a } N(\mu, \sigma^2) \text{ distribution if and only if } Z = \frac{X-\mu}{\sigma} \text{ has a } N(0, 1) \text{ distribution.} \quad (3.4.8)$$

Let X have a $N(\mu, \sigma^2)$ distribution. The graph of the pdf of X is seen in Figure 3.4.1 to have the following characteristics: (1) symmetry about a vertical axis through $x = \mu$; (2) having its maximum of $1/(\sigma\sqrt{2\pi})$ at $x = \mu$; and (3) having the x -axis as a horizontal asymptote. It should also be verified that (4) there are

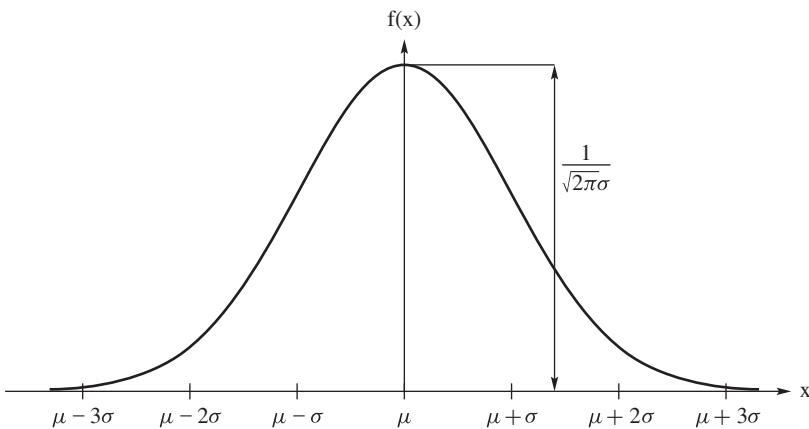

Figure 3.4.1: The normal density $f(x)$, (3.4.6).

points of inflection at $x = \mu \pm \sigma$; see Exercise 3.4.7. By the symmetry about μ , it follows that the median of a normal distribution is equal to its mean.

If we want to determine $P(X \leq x)$, then the following integration is required:

$$P(X \leq x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}\sigma} e^{-(t-\mu)^2/(2\sigma^2)} dt.$$

From calculus we know that the integrand does not have an antiderivative; hence, the integration must be carried out by numerical integration procedures. The R software uses such a procedure for its function `pnorm`. If X has a $N(\mu, \sigma^2)$ distribution, then the R call `pnorm(x, mu, sigma)` computes $P(X \leq x)$, while `q = qnorm(p, mu, sigma)` gives the p th quantile of X ; i.e., q solves the equation $P(X \leq q) = p$. We illustrate this computation in the next example.

Example 3.4.1. Suppose the height in inches of an adult male is normally distributed with mean $\mu = 70$ inches and standard deviation $\sigma = 4$ inches. As a graph of the pdf of X use Figure 3.4.1 replacing μ by 70 and σ by 4. Suppose we want to compute the probability that a man exceeds six feet (72 inches) in height. Locate 72 on the figure. The desired probability is the area under the curve over the interval $(72, \infty)$ which is computed in R by `1 - pnorm(72, 70, 4) = 0.3085`; hence, 31% of males exceed six feet in height. The 95th percentile in height is `qnorm(0.95, 70, 4) = 76.6` inches. What percentage of males have heights within one standard deviation of the mean? Answer: `pnorm(74, 70, 4) - pnorm(66, 70, 4) = 0.6827`. ■

Before the age of modern computing tables of probabilities for normal distributions were formulated. Due to the fact (3.4.8), only tables for the standard normal distribution are required. Let Z have the standard normal distribution. A graph of

its pdf is displayed in Figure 3.4.2. Common notation for the cdf of Z is

$$P(Z \leq z) = \Phi(z) = \text{dfn} \int_0^z \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt, \quad -\infty < z < \infty. \quad (3.4.9)$$

Table II of Appendix D displays a table for $\Phi(z)$ for specified values of $z > 0$. To compute $\Phi(-z)$, where $z > 0$, use the identity

$$\Phi(-z) = 1 - \Phi(z). \quad (3.4.10)$$

This identity follows because the pdf of Z is symmetric about 0. It is apparent in Figure 3.4.2 and the reader is asked to show it in Exercise 3.4.1.

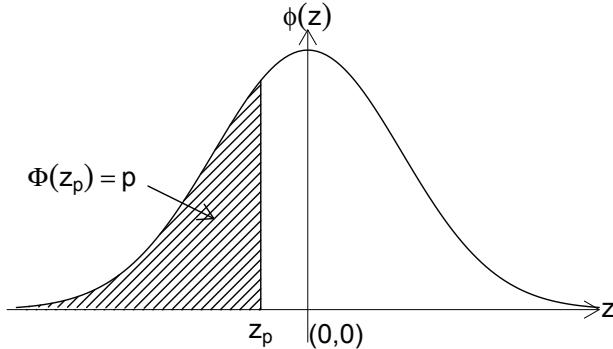

Figure 3.4.2: The standard normal density: $p = \Phi(z_p)$ is the area under the curve to the left of z_p .

As an illustration of the use of Table II, suppose in Example 3.4.1 that we want to determine the probability that the height of an adult male is between 67 and 71 inches. This is calculated as

$$\begin{aligned} P(67 < X < 71) &= P(X < 71) - P(X < 67) \\ &= P\left(\frac{X - 70}{4} < \frac{71 - 70}{4}\right) - P\left(\frac{X - 70}{4} < \frac{67 - 70}{4}\right) \\ &= P(Z < 0.25) - P(Z < -0.75) = \Phi(0.25) - 1 + \Phi(0.75) \\ &= 0.5987 - 1 + 0.7734 = 0.3721 \quad (3.4.11) \\ &= \text{pnorm}(71, 70, 4) - \text{pnorm}(67, 70, 4) = 0.372079. \quad (3.4.12) \end{aligned}$$

Expression (3.4.11) is the calculation by using Table II, while the last line is the calculation by using the R function `pnorm`. More examples are offered in the exercises. As a final note on Table II, it is generated by the R function:

```
normtab <- function(){ za <- seq(0.00,3.59,.01);
  pz <- t(matrix(round(pnorm(za),digits=4),nrow=10))
  colnames(pz) <- seq(0,.09,.01)
  rownames(pz) <- seq(0.0,3.5,.1); return(pz)}
```

The function `normtab` can be downloaded at the site mentioned in the Preface.

Example 3.4.2 (Empirical Rule). Let X be $N(\mu, \sigma^2)$. Then, by Table II or R,

$$\begin{aligned} P(\mu - 2\sigma < X < \mu + 2\sigma) &= \Phi\left(\frac{\mu + 2\sigma - \mu}{\sigma}\right) - \Phi\left(\frac{\mu - 2\sigma - \mu}{\sigma}\right) \\ &= \Phi(2) - \Phi(-2) \\ &= 0.977 - (1 - 0.977) = 0.954. \end{aligned}$$

Similarly, $P(\mu - \sigma < X < \mu + \sigma) = 0.6827$ and $P(\mu - 3\sigma < X < \mu + 3\sigma) = 0.9973$. Sometimes these three intervals and their corresponding probabilities are referred to as the **empirical rule**. Note that we can use Chebyshev's Theorem (Theorem 1.10.3), to obtain lower bounds for these probabilities. While the empirical rule is much more precise, it also requires the assumption of a normal distribution. On the other hand, Chebyshev's theorem requires only the assumption of a finite variance.

■

Example 3.4.3. Suppose that 10% of the probability for a certain distribution that is $N(\mu, \sigma^2)$ is below 60 and that 5% is above 90. What are the values of μ and σ ? We are given that the random variable X is $N(\mu, \sigma^2)$ and that $P(X \leq 60) = 0.10$ and $P(X \leq 90) = 0.95$. Thus $\Phi[(60 - \mu)/\sigma] = 0.10$ and $\Phi[(90 - \mu)/\sigma] = 0.95$. From Table II we have

$$\frac{60 - \mu}{\sigma} = -1.28, \quad \frac{90 - \mu}{\sigma} = 1.64.$$

These conditions require that $\mu = 73.1$ and $\sigma = 10.2$ approximately. ■

Remark 3.4.1. In this chapter we have illustrated three types of **parameters** associated with distributions. The mean μ of $N(\mu, \sigma^2)$ is called a **location parameter** because changing its value simply changes the location of the middle of the normal pdf; that is, the graph of the pdf looks exactly the same except for a shift in location. The standard deviation σ of $N(\mu, \sigma^2)$ is called a **scale parameter** because changing its value changes the spread of the distribution. That is, a small value of σ requires the graph of the normal pdf to be tall and narrow, while a large value of σ requires it to spread out and not be so tall. No matter what the values of μ and σ , however, the graph of the normal pdf is that familiar “bell shape.” Incidentally, the β of the gamma distribution is also a scale parameter. On the other hand, the α of the gamma distribution is called a **shape parameter**, as changing its value modifies the shape of the graph of the pdf, as can be seen by referring to Figure 3.3.1. The parameters p and μ of the binomial and Poisson distributions, respectively, are also shape parameters. ■

Continuing with the first part of Remark 3.4.1, if X is $N(\mu, \sigma^2)$ then we say that X follows the **location model** which we write as

$$X = \mu + e, \tag{3.4.13}$$

where e is a random variable (often called random error) with a $N(0, \sigma^2)$ distribution. Conversely, it follows immediately that if X satisfies expression (3.4.13) with e distributed $N(0, \sigma^2)$ then X has a $N(\mu, \sigma^2)$ distribution.

We close this part of the section with three important results.

Example 3.4.4 (All the Moments of a Normal Distribution). Recall that in Example 1.9.7, we derived all the moments of a standard normal random variable by using its moment generating function. We can use this to obtain all the moments of X , where X has a $N(\mu, \sigma^2)$ distribution. From expression (3.4.13), we can write $X = \sigma Z + \mu$, where Z has a $N(0, 1)$ distribution. Hence, for all nonnegative integers k a simple application of the binomial theorem yields

$$E(X^k) = E[(\sigma Z + \mu)^k] = \sum_{j=0}^k \binom{k}{j} \sigma^j E(Z^j) \mu^{k-j}. \quad (3.4.14)$$

Recall from Example 1.9.7 that all the odd moments of Z are 0, while all the even moments are given by expression (1.9.3). These can be substituted into expression (3.4.14) to derive the moments of X . ■

Theorem 3.4.1. *If the random variable X is $N(\mu, \sigma^2)$, $\sigma^2 > 0$, then the random variable $V = (X - \mu)^2 / \sigma^2$ is $\chi^2(1)$.*

Proof. Because $V = W^2$, where $W = (X - \mu)/\sigma$ is $N(0, 1)$, the cdf $G(v)$ for V is, for $v \geq 0$,

$$G(v) = P(W^2 \leq v) = P(-\sqrt{v} \leq W \leq \sqrt{v}).$$

That is,

$$G(v) = 2 \int_0^{\sqrt{v}} \frac{1}{\sqrt{2\pi}} e^{-w^2/2} dw, \quad 0 \leq v,$$

and

$$G(v) = 0, \quad v < 0.$$

If we change the variable of integration by writing $w = \sqrt{y}$, then

$$G(v) = \int_0^v \frac{1}{\sqrt{2\pi}\sqrt{y}} e^{-y/2} dy, \quad 0 \leq v.$$

Hence the pdf $g(v) = G'(v)$ of the continuous-type random variable V is

$$g(v) = \begin{cases} \frac{1}{\sqrt{\pi}\sqrt{2}} v^{1/2-1} e^{-v/2} & 0 < v < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Since $g(v)$ is a pdf

$$\int_0^\infty g(v) dv = 1;$$

hence, it must be that $\Gamma(\frac{1}{2}) = \sqrt{\pi}$ and thus V is $\chi^2(1)$. ■

One of the most important properties of the normal distribution is its additivity under independence.

Theorem 3.4.2. Let X_1, \dots, X_n be independent random variables such that, for $i = 1, \dots, n$, X_i has a $N(\mu_i, \sigma_i^2)$ distribution. Let $Y = \sum_{i=1}^n a_i X_i$, where a_1, \dots, a_n are constants. Then the distribution of Y is $N(\sum_{i=1}^n a_i \mu_i, \sum_{i=1}^n a_i^2 \sigma_i^2)$.

Proof: By Theorem 2.6.1, for $t \in R$, the mgf of Y is

$$\begin{aligned} M_Y(t) &= \prod_{i=1}^n \exp \left\{ t a_i \mu_i + (1/2) t^2 a_i^2 \sigma_i^2 \right\} \\ &= \exp \left\{ t \sum_{i=1}^n a_i \mu_i + (1/2) t^2 \sum_{i=1}^n a_i^2 \sigma_i^2 \right\}, \end{aligned}$$

which is the mgf of a $N(\sum_{i=1}^n a_i \mu_i, \sum_{i=1}^n a_i^2 \sigma_i^2)$ distribution. ■

A simple corollary to this result gives the distribution of the sample mean $\bar{X} = n^{-1} \sum_{i=1}^n X_i$ when X_1, X_2, \dots, X_n represents a random sample from a $N(\mu, \sigma^2)$.

Corollary 3.4.1. Let X_1, \dots, X_n be iid random variables with a common $N(\mu, \sigma^2)$ distribution. Let $\bar{X} = n^{-1} \sum_{i=1}^n X_i$. Then \bar{X} has a $N(\mu, \sigma^2/n)$ distribution.

To prove this corollary, simply take $a_i = (1/n)$, $\mu_i = \mu$, and $\sigma_i^2 = \sigma^2$, for $i = 1, 2, \dots, n$, in Theorem 3.4.2.

3.4.1 *Contaminated Normals

We next discuss a random variable whose distribution is a mixture of normals. As with the normal, we begin with a standardized random variable.

Suppose we are observing a random variable that most of the time follows a standard normal distribution but occasionally follows a normal distribution with a larger variance. In applications, we might say that most of the data are “good” but that there are occasional outliers. To make this precise let Z have a $N(0, 1)$ distribution; let $I_{1-\epsilon}$ be a discrete random variable defined by

$$I_{1-\epsilon} = \begin{cases} 1 & \text{with probability } 1 - \epsilon \\ 0 & \text{with probability } \epsilon, \end{cases}$$

and assume that Z and $I_{1-\epsilon}$ are independent. Let $W = Z I_{1-\epsilon} + \sigma_c Z(1 - I_{1-\epsilon})$. Then W is the random variable of interest.

The independence of Z and $I_{1-\epsilon}$ imply that the cdf of W is

$$\begin{aligned} F_W(w) = P[W \leq w] &= P[W \leq w, I_{1-\epsilon} = 1] + P[W \leq w, I_{1-\epsilon} = 0] \\ &= P[W \leq w | I_{1-\epsilon} = 1] P[I_{1-\epsilon} = 1] \\ &\quad + P[W \leq w | I_{1-\epsilon} = 0] P[I_{1-\epsilon} = 0] \\ &= P[Z \leq w](1 - \epsilon) + P[Z \leq w/\sigma_c]\epsilon. \\ &= \Phi(w)(1 - \epsilon) + \Phi(w/\sigma_c)\epsilon \end{aligned} \tag{3.4.15}$$

Therefore, we have shown that the distribution of W is a mixture of normals. Further, because $W = Z I_{1-\epsilon} + \sigma_c Z(1 - I_{1-\epsilon})$, we have

$$E(W) = 0 \text{ and } \text{Var}(W) = 1 + \epsilon(\sigma_c^2 - 1); \tag{3.4.16}$$

see Exercise 3.4.24. Upon differentiating (3.4.15), the pdf of W is

$$f_W(w) = \phi(w)(1 - \epsilon) + \phi(w/\sigma_c) \frac{\epsilon}{\sigma_c}, \quad (3.4.17)$$

where ϕ is the pdf of a standard normal.

Suppose, in general, that the random variable of interest is $X = a + bW$, where $b > 0$. Based on (3.4.16), the mean and variance of X are

$$E(X) = a \text{ and } \text{Var}(X) = b^2(1 + \epsilon(\sigma_c^2 - 1)). \quad (3.4.18)$$

From expression (3.4.15), the cdf of X is

$$F_X(x) = \Phi\left(\frac{x-a}{b}\right)(1-\epsilon) + \Phi\left(\frac{x-a}{b\sigma_c}\right)\epsilon, \quad (3.4.19)$$

which is a mixture of normal cdfs.

Based on expression (3.4.19) it is easy to obtain probabilities for contaminated normal distributions using R. For example, suppose, as above, W has cdf (3.4.15). Then $P(W \leq w)$ is obtained by the R command `(1-eps)*pnorm(w) + eps*pnorm(w/sigc)`, where `eps` and `sigc` denote ϵ and σ_c , respectively. Similarly, the pdf of W at w is returned by `(1-eps)*dnorm(w) + eps*dnorm(w/sigc)/sigc`. The functions `pcn` and `dcn`⁷ compute the cdf and pdf of the contaminated normal, respectively. In Section 3.7, we explore mixture distributions in general.

EXERCISES

3.4.1. If

$$\Phi(z) = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-w^2/2} dw,$$

show that $\Phi(-z) = 1 - \Phi(z)$.

3.4.2. If X is $N(75, 100)$, find $P(X < 60)$ and $P(70 < X < 100)$ by using either Table II or the R command `pnorm`.

3.4.3. If X is $N(\mu, \sigma^2)$, find b so that $P[-b < (X - \mu)/\sigma < b] = 0.90$, by using either Table II of Appendix D or the R command `qnorm`.

3.4.4. Let X be $N(\mu, \sigma^2)$ so that $P(X < 89) = 0.90$ and $P(X < 94) = 0.95$. Find μ and σ^2 .

3.4.5. Show that the constant c can be selected so that $f(x) = c2^{-x^2}$, $-\infty < x < \infty$, satisfies the conditions of a normal pdf.

Hint: Write $2 = e^{\log 2}$.

3.4.6. If X is $N(\mu, \sigma^2)$, show that $E(|X - \mu|) = \sigma\sqrt{2/\pi}$.

3.4.7. Show that the graph of a pdf $N(\mu, \sigma^2)$ has points of inflection at $x = \mu - \sigma$ and $x = \mu + \sigma$.

⁷Downloadable at the site listed in the Preface.

3.4.8. Evaluate $\int_2^3 \exp[-2(x-3)^2] dx$.

3.4.9. Determine the 90th percentile of the distribution, which is $N(65, 25)$.

3.4.10. If e^{3t+8t^2} is the mgf of the random variable X , find $P(-1 < X < 9)$.

3.4.11. Let the random variable X have the pdf

$$f(x) = \frac{2}{\sqrt{2\pi}} e^{-x^2/2}, \quad 0 < x < \infty, \quad \text{zero elsewhere.}$$

(a) Find the mean and the variance of X .

(b) Find the cdf and hazard function of X .

Hint for (a): Compute $E(X)$ directly and $E(X^2)$ by comparing the integral with the integral representing the variance of a random variable that is $N(0, 1)$.

3.4.12. Let X be $N(5, 10)$. Find $P[0.04 < (X - 5)^2 < 38.4]$.

3.4.13. If X is $N(1, 4)$, compute the probability $P(1 < X^2 < 9)$.

3.4.14. If X is $N(75, 25)$, find the conditional probability that X is greater than 80 given that X is greater than 77. See Exercise 2.3.12.

3.4.15. Let X be a random variable such that $E(X^{2m}) = (2m)!/(2^m m!)$, $m = 1, 2, 3, \dots$ and $E(X^{2m-1}) = 0$, $m = 1, 2, 3, \dots$. Find the mgf and the pdf of X .

3.4.16. Let the mutually independent random variables X_1 , X_2 , and X_3 be $N(0, 1)$, $N(2, 4)$, and $N(-1, 1)$, respectively. Compute the probability that exactly two of these three variables are less than zero.

3.4.17. Compute the measures of skewness and kurtosis of a distribution which is $N(\mu, \sigma^2)$. See Exercises 1.9.14 and 1.9.15 for the definitions of skewness and kurtosis, respectively.

3.4.18. Let the random variable X have a distribution that is $N(\mu, \sigma^2)$.

(a) Does the random variable $Y = X^2$ also have a normal distribution?

(b) Would the random variable $Y = aX + b$, a and b nonzero constants have a normal distribution?

Hint: In each case, first determine $P(Y \leq y)$.

3.4.19. Let the random variable X be $N(\mu, \sigma^2)$. What would this distribution be if $\sigma^2 = 0$?

Hint: Look at the mgf of X for $\sigma^2 > 0$ and investigate its limit as $\sigma^2 \rightarrow 0$.

3.4.20. Let Y have a **truncated** distribution with pdf $g(y) = \phi(y)/[\Phi(b) - \Phi(a)]$, for $a < y < b$, zero elsewhere, where $\phi(x)$ and $\Phi(x)$ are, respectively, the pdf and distribution function of a standard normal distribution. Show then that $E(Y)$ is equal to $[\phi(a) - \phi(b)]/[\Phi(b) - \Phi(a)]$.

3.4.21. Let $f(x)$ and $F(x)$ be the pdf and the cdf, respectively, of a distribution of the continuous type such that $f'(x)$ exists for all x . Let the mean of the truncated distribution that has pdf $g(y) = f(y)/F(b)$, $-\infty < y < b$, zero elsewhere, be equal to $-f(b)/F(b)$ for all real b . Prove that $f(x)$ is a pdf of a standard normal distribution.

3.4.22. Let X and Y be independent random variables, each with a distribution that is $N(0, 1)$. Let $Z = X + Y$. Find the integral that represents the cdf $G(z) = P(X + Y \leq z)$ of Z . Determine the pdf of Z .

Hint: We have that $G(z) = \int_{-\infty}^{\infty} H(x, z) dx$, where

$$H(x, z) = \int_{-\infty}^{z-x} \frac{1}{2\pi} \exp[-(x^2 + y^2)/2] dy.$$

Find $G'(z)$ by evaluating $\int_{-\infty}^{\infty} [\partial H(x, z)/\partial z] dx$.

3.4.23. Suppose X is a random variable with the pdf $f(x)$ which is symmetric about 0; i.e., $f(-x) = f(x)$. Show that $F(-x) = 1 - F(x)$, for all x in the support of X .

3.4.24. Derive the mean and variance of a contaminated normal random variable. They are given in expression (3.4.16).

3.4.25. Investigate the probabilities of an “outlier” for a contaminated normal random variable and a normal random variable. Specifically, determine the probability of observing the event $\{|X| \geq 2\}$ for the following random variables (use the R function `pcn` for the contaminated normals):

- (a) X has a standard normal distribution.
- (b) X has a contaminated normal distribution with cdf (3.4.15), where $\epsilon = 0.15$ and $\sigma_c = 10$.
- (c) X has a contaminated normal distribution with cdf (3.4.15), where $\epsilon = 0.15$ and $\sigma_c = 20$.
- (d) X has a contaminated normal distribution with cdf (3.4.15), where $\epsilon = 0.25$ and $\sigma_c = 20$.

3.4.26. Plot the pdfs of the random variables defined in parts (a)–(d) of the last exercise. Obtain an overlay plot of all four pdfs also. In R the domain values of the pdfs can easily be obtained by using the `seq` command. For instance, the command `x<-seq(-6,6,.1)` returns a vector of values between -6 and 6 in jumps of 0.1 . Then use the R function `dcn` for the contaminated normal pdfs.

3.4.27. Consider the family of pdfs indexed by the parameter α , $-\infty < \alpha < \infty$, given by

$$f(x; \alpha) = 2\phi(x)\Phi(\alpha x), \quad -\infty < x < \infty, \quad (3.4.20)$$

where $\phi(x)$ and $\Phi(x)$ are respectively the pdf and cdf of a standard normal distribution.

- (a) Clearly $f(x; \alpha) > 0$ for all x . Show that the pdf integrates to 1 over $(-\infty, \infty)$.

Hint: Start with

$$\int_{-\infty}^{\infty} f(x; \alpha) dx = 2 \int_{-\infty}^{\infty} \phi(x) \int_{-\infty}^{\alpha x} \phi(t) dt.$$

Next sketch the region of integration and then combine the integrands and use the polar coordinate transformation we used after expression (3.4.1).

- (b) Note that $f(x; \alpha)$ is the $N(0, 1)$ pdf for $\alpha = 0$. The pdfs are left skewed for $\alpha < 0$ and right skewed for $\alpha > 0$. Using R, verify this by plotting the pdfs for $\alpha = -3, -2, -1, 1, 2, 3$. Here's the code for $\alpha = -3$:

```
x=seq(-5,5,.01); alp=-3; y=2*dnorm(x)*pnorm(alp*x); plot(y~x)
```

This family is called the **skewed normal family**; see Azzalini (1985).

- 3.4.28.** For Z distributed $N(0, 1)$, it can be shown that

$$E[\Phi(hZ + k)] = \Phi[k/\sqrt{1+h^2}];$$

see Azzalini (1985). Use this fact to obtain the mgf of the pdf (3.4.20). Next obtain the mean of this pdf.

- 3.4.29.** Let X_1 and X_2 be independent with normal distributions $N(6, 1)$ and $N(7, 1)$, respectively. Find $P(X_1 > X_2)$.

Hint: Write $P(X_1 > X_2) = P(X_1 - X_2 > 0)$ and determine the distribution of $X_1 - X_2$.

- 3.4.30.** Compute $P(X_1 + 2X_2 - 2X_3 > 7)$ if X_1, X_2, X_3 are iid with common distribution $N(1, 4)$.

- 3.4.31.** A certain job is completed in three steps in series. The means and standard deviations for the steps are (in minutes)

Step	Mean	Standard Deviation
1	17	2
2	13	1
3	13	2

Assuming independent steps and normal distributions, compute the probability that the job takes less than 40 minutes to complete.

- 3.4.32.** Let X be $N(0, 1)$. Use the moment generating function technique to show that $Y = X^2$ is $\chi^2(1)$.

Hint: Evaluate the integral that represents $E(e^{tX^2})$ by writing $w = x\sqrt{1-2t}$, $t < \frac{1}{2}$.

- 3.4.33.** Suppose X_1, X_2 are iid with a common standard normal distribution. Find the joint pdf of $Y_1 = X_1^2 + X_2^2$ and $Y_2 = X_2$ and the marginal pdf of Y_1 .

Hint: Note that the space of Y_1 and Y_2 is given by $-\sqrt{y_1} < y_2 < \sqrt{y_1}, 0 < y_1 < \infty$.

3.5 The Multivariate Normal Distribution

In this section we present the multivariate normal distribution. In the first part of the section, we introduce the bivariate normal distribution, leaving most of the proofs to the later section, Section 3.5.2.

3.5.1 Bivariate Normal Distribution

We say that (X, Y) follows a **bivariate normal distribution** if its pdf is given by

$$f(x, y) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} e^{-q/2}, \quad -\infty < x < \infty, \quad -\infty < y < \infty, \quad (3.5.1)$$

where

$$q = \frac{1}{1-\rho^2} \left[\left(\frac{x-\mu_1}{\sigma_1} \right)^2 - 2\rho \left(\frac{x-\mu_1}{\sigma_1} \right) \left(\frac{y-\mu_2}{\sigma_2} \right) + \left(\frac{y-\mu_2}{\sigma_2} \right)^2 \right], \quad (3.5.2)$$

and $-\infty < \mu_i < \infty$, $\sigma_i > 0$, for $i = 1, 2$, and ρ satisfies $\rho^2 < 1$. Clearly, this function is positive everywhere in R^2 . As we show in Section 3.5.2, it is a pdf with the mgf given by:

$$M_{(X,Y)}(t_1, t_2) = \exp \left\{ t_1\mu_1 + t_2\mu_2 + \frac{1}{2}(t_1^2\sigma_1^2 + 2t_1t_2\rho\sigma_1\sigma_2 + t_2^2\sigma_2^2) \right\}. \quad (3.5.3)$$

Thus, the mgf of X is

$$M_X(t_1) = M_{(X,Y)}(t_1, 0) = \exp \left\{ t_1\mu_1 + \frac{1}{2}t_1^2\sigma_1^2 \right\};$$

hence, X has a $N(\mu_1, \sigma_1^2)$ distribution. In the same way, Y has a $N(\mu_2, \sigma_2^2)$ distribution. Thus μ_1 and μ_2 are the respective means of X and Y and σ_1^2 and σ_2^2 are the respective variances of X and Y . For the parameter ρ , Exercise 3.5.3 shows that

$$E(XY) = \frac{\partial^2 M_{(X,Y)}}{\partial t_1 \partial t_2}(0, 0) = \rho\sigma_1\sigma_2 + \mu_1\mu_2. \quad (3.5.4)$$

Hence, $\text{cov}(X, Y) = \rho\sigma_1\sigma_2$ and thus, as the notation suggests, ρ is the correlation coefficient between X and Y . We know by Theorem 2.5.2 that if X and Y are independent then $\rho = 0$. Further, from expression (3.5.3), if $\rho = 0$ then the joint mgf of (X, Y) factors into the product of the marginal mgfs and, hence, X and Y are independent random variables. Thus if (X, Y) has a bivariate normal distribution, then X and Y are independent if and only if they are uncorrelated.

The bivariate normal pdf, (3.5.1), is mound shaped over R^2 and peaks at its mean (μ_1, μ_2) ; see Exercise 3.5.4. For a given $c > 0$, the points of equal probability (or density) are given by $\{(x, y) : f(x, y) = c\}$. It follows with some algebra that these sets are ellipses. In general for multivariate distributions, we call these sets **contours** of the pdfs. Hence, the contours of bivariate normal distributions are

elliptical. If X and Y are independent then these contours are circular. The interested reader can consult a book on multivariate statistics for discussions on the geometry of the ellipses. For example, if $\sigma_1 = \sigma_2$ and $\rho > 0$, the main axis of the ellipse goes through the mean at a 45° angle; see Johnson and Wichern (2008) for discussion.

Figure 3.5.1 displays a three-dimensional plot of the bivariate normal pdf with $(\mu_1, \mu_2) = (0, 0)$, $\sigma_1 = \sigma_2 = 1$, and $\rho = 0.5$. For location, the peak is at $(\mu_1, \mu_2) = (0, 0)$. The elliptical contours are apparent. Locate the main axis. For a region A in the plane, $P[(X, Y) \in A]$ is the volume under the surface over A . In general such probabilities are calculated by numerical integration methods.

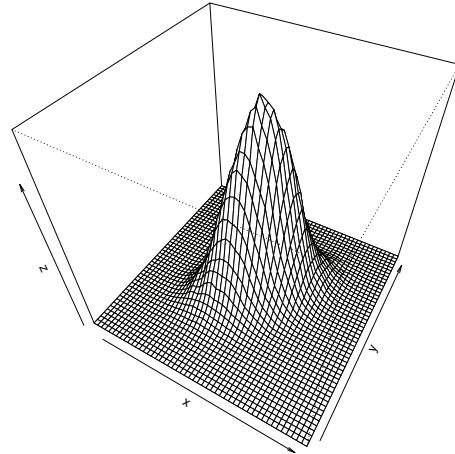

Figure 3.5.1: A sketch of the surface of a bivariate normal distribution with mean $(0, 0)$, $\sigma_1 = \sigma_2 = 1$, and $\rho = 0.5$.

In the next section, we extend the discussion to the general multivariate case; however, Remark 3.5.1, below, returns to the bivariate case and can be read with minor knowledge of vector and matrices.

3.5.2 *Multivariate Normal Distribution, General Case

In this section we generalize the bivariate normal distribution to the n -dimensional multivariate normal distribution. As with Section 3.4 on the normal distribution, the derivation of the distribution is simplified by first discussing the standardized variable case and then proceeding to the general case. Also, in this section, vector and matrix notation are used.

Consider the random vector $\mathbf{Z} = (Z_1, \dots, Z_n)'$, where Z_1, \dots, Z_n are iid $N(0, 1)$ random variables. Then the density of \mathbf{Z} is

$$\begin{aligned} f_{\mathbf{Z}}(\mathbf{z}) &= \prod_{i=1}^n \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}z_i^2\right\} = \left(\frac{1}{2\pi}\right)^{n/2} \exp\left\{-\frac{1}{2}\sum_{i=1}^n z_i^2\right\} \\ &= \left(\frac{1}{2\pi}\right)^{n/2} \exp\left\{-\frac{1}{2}\mathbf{z}'\mathbf{z}\right\}, \end{aligned} \quad (3.5.5)$$

for $\mathbf{z} \in R^n$. Because the Z_i s have mean 0, have variance 1, and are uncorrelated, the mean and covariance matrix of \mathbf{Z} are

$$E[\mathbf{Z}] = \mathbf{0} \text{ and } \text{Cov}[\mathbf{Z}] = \mathbf{I}_n, \quad (3.5.6)$$

where \mathbf{I}_n denotes the identity matrix of order n . Recall that the mgf of Z_i evaluated at t_i is $\exp\{t_i^2/2\}$. Hence, because the Z_i s are independent, the mgf of \mathbf{Z} is

$$\begin{aligned} M_{\mathbf{Z}}(\mathbf{t}) = E[\exp\{\mathbf{t}'\mathbf{Z}\}] &= E\left[\prod_{i=1}^n \exp\{t_i Z_i\}\right] = \prod_{i=1}^n E[\exp\{t_i Z_i\}] \\ &= \exp\left\{\frac{1}{2}\sum_{i=1}^n t_i^2\right\} = \exp\left\{\frac{1}{2}\mathbf{t}'\mathbf{t}\right\}, \end{aligned} \quad (3.5.7)$$

for all $\mathbf{t} \in R^n$. We say that \mathbf{Z} has a **multivariate normal distribution** with mean vector $\mathbf{0}$ and covariance matrix \mathbf{I}_n . We abbreviate this by saying that \mathbf{Z} has an $N_n(\mathbf{0}, \mathbf{I}_n)$ distribution.

For the general case, suppose Σ is an $n \times n$, symmetric, and positive semi-definite matrix. Then from linear algebra, we can always decompose Σ as

$$\Sigma = \Gamma' \Lambda \Gamma, \quad (3.5.8)$$

where Λ is the diagonal matrix $\Lambda = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n)$, $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n \geq 0$ are the eigenvalues of Σ , and the columns of Γ' , $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$, are the corresponding eigenvectors. This decomposition is called the **spectral decomposition** of Σ . The matrix Γ is orthogonal, i.e., $\Gamma^{-1} = \Gamma'$, and, hence, $\Gamma\Gamma' = \mathbf{I}$. As Exercise 3.5.19 shows, we can write the spectral decomposition in another way, as

$$\Sigma = \Gamma' \Lambda \Gamma = \sum_{i=1}^n \lambda_i \mathbf{v}_i \mathbf{v}_i'. \quad (3.5.9)$$

Because the λ_i s are nonnegative, we can define the diagonal matrix $\Lambda^{1/2} = \text{diag}\{\sqrt{\lambda_1}, \dots, \sqrt{\lambda_n}\}$. Then the orthogonality of Γ implies

$$\Sigma = [\Gamma' \Lambda^{1/2} \Gamma][\Gamma' \Lambda^{1/2} \Gamma].$$

We define the matrix product in brackets as the **square root** of the positive semi-definite matrix Σ and write it as

$$\Sigma^{1/2} = \Gamma' \Lambda^{1/2} \Gamma. \quad (3.5.10)$$

Note that $\Sigma^{1/2}$ is symmetric and positive semi-definite. Suppose Σ is positive definite; that is, all of its eigenvalues are strictly positive. Based on this, it is then easy to show that

$$\left(\Sigma^{1/2}\right)^{-1} = \mathbf{I}' \boldsymbol{\Lambda}^{-1/2} \mathbf{I}; \quad (3.5.11)$$

see Exercise 3.5.13. We write the left side of this equation as $\Sigma^{-1/2}$. These matrices enjoy many additional properties of the law of exponents for numbers; see, for example, Arnold (1981). Here, though, all we need are the properties given above.

Suppose \mathbf{Z} has a $N_n(\mathbf{0}, \mathbf{I}_n)$ distribution. Let Σ be a positive semi-definite, symmetric matrix and let $\boldsymbol{\mu}$ be an $n \times 1$ vector of constants. Define the random vector \mathbf{X} by

$$\mathbf{X} = \Sigma^{1/2} \mathbf{Z} + \boldsymbol{\mu}. \quad (3.5.12)$$

By (3.5.6) and Theorem 2.6.3, we immediately have

$$E[\mathbf{X}] = \boldsymbol{\mu} \text{ and } \text{Cov}[\mathbf{X}] = \Sigma^{1/2} \Sigma^{1/2} = \Sigma. \quad (3.5.13)$$

Further, the mgf of \mathbf{X} is given by

$$\begin{aligned} M_{\mathbf{X}}(\mathbf{t}) = E[\exp\{\mathbf{t}' \mathbf{X}\}] &= E\left[\exp\{\mathbf{t}' \Sigma^{1/2} \mathbf{Z} + \mathbf{t}' \boldsymbol{\mu}\}\right] \\ &= \exp\{\mathbf{t}' \boldsymbol{\mu}\} E\left[\exp\left\{\left(\Sigma^{1/2} \mathbf{t}\right)' \mathbf{Z}\right\}\right] \\ &= \exp\{\mathbf{t}' \boldsymbol{\mu}\} \exp\left\{(1/2)\left(\Sigma^{1/2} \mathbf{t}\right)' \Sigma^{1/2} \mathbf{t}\right\} \\ &= \exp\{\mathbf{t}' \boldsymbol{\mu}\} \exp\{(1/2)\mathbf{t}' \Sigma \mathbf{t}\}. \end{aligned} \quad (3.5.14)$$

This leads to the following definition:

Definition 3.5.1 (Multivariate Normal). *We say an n -dimensional random vector \mathbf{X} has a multivariate normal distribution if its mgf is*

$$M_{\mathbf{X}}(\mathbf{t}) = \exp\{\mathbf{t}' \boldsymbol{\mu} + (1/2)\mathbf{t}' \Sigma \mathbf{t}\}, \text{ for all } \mathbf{t} \in R^n. \quad (3.5.15)$$

where Σ is a symmetric, positive semi-definite matrix and $\boldsymbol{\mu} \in R^n$. We abbreviate this by saying that \mathbf{X} has a $N_n(\boldsymbol{\mu}, \Sigma)$ distribution.

Note that our definition is for positive semi-definite matrices Σ . Usually Σ is positive definite, in which case we can further obtain the density of \mathbf{X} . If Σ is positive definite, then so is $\Sigma^{1/2}$ and, as discussed above, its inverse is given by expression (3.5.11). Thus the transformation between \mathbf{X} and \mathbf{Z} , (3.5.12), is one-to-one with the inverse transformation

$$\mathbf{Z} = \Sigma^{-1/2}(\mathbf{X} - \boldsymbol{\mu})$$

and the Jacobian $|\Sigma^{-1/2}| = |\Sigma|^{-1/2}$. Hence, upon simplification, the pdf of \mathbf{X} is given by

$$f_{\mathbf{X}}(\mathbf{x}) = \frac{1}{(2\pi)^{n/2} |\Sigma|^{1/2}} \exp\left\{-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu})' \Sigma^{-1} (\mathbf{x} - \boldsymbol{\mu})\right\}, \text{ for } \mathbf{x} \in R^n. \quad (3.5.16)$$

In Section 3.5.1, we discussed the contours of the bivariate normal distribution. We now extend that discussion to the general case, adding probabilities to the contours. Let \mathbf{X} have a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution. In the n -dimensional case, the contours of constant probability for the pdf of \mathbf{X} , (3.5.16), are the ellipsoids

$$(\mathbf{x} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu}) = c^2,$$

for $c > 0$. Define the random variable $Y = (\mathbf{X} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{X} - \boldsymbol{\mu})$. Then using expression (3.5.12), we have

$$Y = \mathbf{Z}' \boldsymbol{\Sigma}^{1/2} \boldsymbol{\Sigma}^{-1} \boldsymbol{\Sigma}^{1/2} \mathbf{Z} = \mathbf{Z}' \mathbf{Z} = \sum_{i=1}^n Z_i^2.$$

Since Z_1, \dots, Z_n are iid $N(0, 1)$, Y has χ^2 -distribution with n degrees of freedom. Denote the cdf of Y by $F_{\chi_n^2}$. Then we have

$$P[(\mathbf{X} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{X} - \boldsymbol{\mu}) \leq c^2] = P(Y \leq c^2) = F_{\chi_n^2}(c^2). \quad (3.5.17)$$

These probabilities are often used to label the contour plots; see Exercise 3.5.5. For reference, we summarize the above proof in the following theorem. Note that this theorem is a generalization of the univariate result given in Theorem 3.4.1.

Theorem 3.5.1. *Suppose \mathbf{X} has a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, where $\boldsymbol{\Sigma}$ is positive definite. Then the random variable $Y = (\mathbf{X} - \boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{X} - \boldsymbol{\mu})$ has a $\chi^2(n)$ distribution.*

The following two theorems are very useful. The first says that a linear transformation of a multivariate normal random vector has a multivariate normal distribution.

Theorem 3.5.2. *Suppose \mathbf{X} has a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution. Let $\mathbf{Y} = \mathbf{AX} + \mathbf{b}$, where \mathbf{A} is an $m \times n$ matrix and $\mathbf{b} \in R^m$. Then \mathbf{Y} has a $N_m(\mathbf{A}\boldsymbol{\mu} + \mathbf{b}, \mathbf{A}\boldsymbol{\Sigma}\mathbf{A}')$ distribution.*

Proof: From (3.5.15), for $\mathbf{t} \in R^m$, the mgf of \mathbf{Y} is

$$\begin{aligned} M_{\mathbf{Y}}(\mathbf{t}) &= E[\exp\{\mathbf{t}' \mathbf{Y}\}] \\ &= E[\exp\{\mathbf{t}' (\mathbf{AX} + \mathbf{b})\}] \\ &= \exp\{\mathbf{t}' \mathbf{b}\} E[\exp\{(\mathbf{A}' \mathbf{t})' \mathbf{X}\}] \\ &= \exp\{\mathbf{t}' \mathbf{b}\} \exp\{(\mathbf{A}' \mathbf{t})' \boldsymbol{\mu} + (1/2)(\mathbf{A}' \mathbf{t})' \boldsymbol{\Sigma} (\mathbf{A}' \mathbf{t})\} \\ &= \exp\{\mathbf{t}' (\mathbf{A}\boldsymbol{\mu} + \mathbf{b}) + (1/2)\mathbf{t}' \mathbf{A}\boldsymbol{\Sigma}\mathbf{A}'\mathbf{t}\}, \end{aligned}$$

which is the mgf of an $N_m(\mathbf{A}\boldsymbol{\mu} + \mathbf{b}, \mathbf{A}\boldsymbol{\Sigma}\mathbf{A}')$ distribution. ■

A simple corollary to this theorem gives marginal distributions of a multivariate normal random variable. Let \mathbf{X}_1 be any subvector of \mathbf{X} , say of dimension $m < n$. Because we can always rearrange means and correlations, there is no loss in generality in writing \mathbf{X} as

$$\mathbf{X} = \begin{bmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \end{bmatrix}, \quad (3.5.18)$$

where \mathbf{X}_2 is of dimension $p = n - m$. In the same way, partition the mean and covariance matrix of \mathbf{X} ; that is,

$$\boldsymbol{\mu} = \begin{bmatrix} \boldsymbol{\mu}_1 \\ \boldsymbol{\mu}_2 \end{bmatrix} \text{ and } \boldsymbol{\Sigma} = \begin{bmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix} \quad (3.5.19)$$

with the same dimensions as in expression (3.5.18). Note, for instance, that $\boldsymbol{\Sigma}_{11}$ is the covariance matrix of \mathbf{X}_1 and $\boldsymbol{\Sigma}_{12}$ contains all the covariances between the components of \mathbf{X}_1 and \mathbf{X}_2 . Now define \mathbf{A} to be the matrix

$$\mathbf{A} = [\mathbf{I}_m : \mathbf{O}_{mp}],$$

where \mathbf{O}_{mp} is an $m \times p$ matrix of zeroes. Then $\mathbf{X}_1 = \mathbf{AX}$. Hence, applying Theorem 3.5.2 to this transformation, along with some matrix algebra, we have the following corollary:

Corollary 3.5.1. *Suppose \mathbf{X} has a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, partitioned as in expressions (3.5.18) and (3.5.19). Then \mathbf{X}_1 has a $N_m(\boldsymbol{\mu}_1, \boldsymbol{\Sigma}_{11})$ distribution.*

This is a useful result because it says that any marginal distribution of \mathbf{X} is also normal and, further, its mean and covariance matrix are those associated with that partial vector.

Recall in Section 2.5, Theorem 2.5.2, that if two random variables are independent then their covariance is 0. In general, the converse is not true. However, as the following theorem shows, it is true for the multivariate normal distribution.

Theorem 3.5.3. *Suppose \mathbf{X} has a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, partitioned as in the expressions (3.5.18) and (3.5.19). Then \mathbf{X}_1 and \mathbf{X}_2 are independent if and only if $\boldsymbol{\Sigma}_{12} = \mathbf{O}$.*

Proof: First note that $\boldsymbol{\Sigma}_{21} = \boldsymbol{\Sigma}'_{12}$. The joint mgf of \mathbf{X}_1 and \mathbf{X}_2 is given by

$$M_{\mathbf{X}_1, \mathbf{X}_2}(\mathbf{t}_1, \mathbf{t}_2) = \exp \left\{ \mathbf{t}'_1 \boldsymbol{\mu}_1 + \mathbf{t}'_2 \boldsymbol{\mu}_2 + \frac{1}{2} (\mathbf{t}'_1 \boldsymbol{\Sigma}_{11} \mathbf{t}_1 + \mathbf{t}'_2 \boldsymbol{\Sigma}_{22} \mathbf{t}_2 + \mathbf{t}'_2 \boldsymbol{\Sigma}_{21} \mathbf{t}_1 + \mathbf{t}'_1 \boldsymbol{\Sigma}_{12} \mathbf{t}_2) \right\} \quad (3.5.20)$$

where $\mathbf{t}' = (\mathbf{t}'_1, \mathbf{t}'_2)$ is partitioned the same as $\boldsymbol{\mu}$. By Corollary 3.5.1, \mathbf{X}_1 has a $N_m(\boldsymbol{\mu}_1, \boldsymbol{\Sigma}_{11})$ distribution and \mathbf{X}_2 has a $N_p(\boldsymbol{\mu}_2, \boldsymbol{\Sigma}_{22})$ distribution. Hence, the product of their marginal mgfs is

$$M_{\mathbf{X}_1}(\mathbf{t}_1) M_{\mathbf{X}_2}(\mathbf{t}_2) = \exp \left\{ \mathbf{t}'_1 \boldsymbol{\mu}_1 + \mathbf{t}'_2 \boldsymbol{\mu}_2 + \frac{1}{2} (\mathbf{t}'_1 \boldsymbol{\Sigma}_{11} \mathbf{t}_1 + \mathbf{t}'_2 \boldsymbol{\Sigma}_{22} \mathbf{t}_2) \right\}. \quad (3.5.21)$$

By (2.6.6) of Section 2.6, \mathbf{X}_1 and \mathbf{X}_2 are independent if and only if the expressions (3.5.20) and (3.5.21) are the same. If $\boldsymbol{\Sigma}_{12} = \mathbf{O}'$ and, hence, $\boldsymbol{\Sigma}_{21} = \mathbf{O}$, then the expressions are the same and \mathbf{X}_1 and \mathbf{X}_2 are independent. If \mathbf{X}_1 and \mathbf{X}_2 are independent, then the covariances between their components are all 0; i.e., $\boldsymbol{\Sigma}_{12} = \mathbf{O}'$ and $\boldsymbol{\Sigma}_{21} = \mathbf{O}$. ■

Corollary 3.5.1 showed that the marginal distributions of a multivariate normal are themselves normal. This is true for conditional distributions, too. As the

following proof shows, we can combine the results of Theorems 3.5.2 and 3.5.3 to obtain the following theorem.

Theorem 3.5.4. Suppose \mathbf{X} has a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, which is partitioned as in expressions (3.5.18) and (3.5.19). Assume that $\boldsymbol{\Sigma}$ is positive definite. Then the conditional distribution of $\mathbf{X}_1 | \mathbf{X}_2$ is

$$N_m(\boldsymbol{\mu}_1 + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}(\mathbf{X}_2 - \boldsymbol{\mu}_2), \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}). \quad (3.5.22)$$

Proof: Consider first the joint distribution of the random vector $\mathbf{W} = \mathbf{X}_1 - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\mathbf{X}_2$ and \mathbf{X}_2 . This distribution is obtained from the transformation

$$\begin{bmatrix} \mathbf{W} \\ \mathbf{X}_2 \end{bmatrix} = \begin{bmatrix} \mathbf{I}_m & -\boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1} \\ \mathbf{O} & \mathbf{I}_p \end{bmatrix} \begin{bmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \end{bmatrix}.$$

Because this is a linear transformation, it follows from Theorem 3.5.2 that the joint distribution is multivariate normal, with $E[\mathbf{W}] = \boldsymbol{\mu}_1 - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\mu}_2$, $E[\mathbf{X}_2] = \boldsymbol{\mu}_2$, and covariance matrix

$$\begin{bmatrix} \mathbf{I}_m & -\boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1} \\ \mathbf{O} & \mathbf{I}_p \end{bmatrix} \begin{bmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix} \begin{bmatrix} \mathbf{I}_m & \mathbf{O}' \\ -\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21} & \mathbf{I}_p \end{bmatrix} = \begin{bmatrix} \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21} & \mathbf{O}' \\ \mathbf{O} & \boldsymbol{\Sigma}_{22} \end{bmatrix}.$$

Hence, by Theorem 3.5.3 the random vectors \mathbf{W} and \mathbf{X}_2 are independent. Thus the conditional distribution of $\mathbf{W} | \mathbf{X}_2$ is the same as the marginal distribution of \mathbf{W} ; that is,

$$\mathbf{W} | \mathbf{X}_2 \text{ is } N_m(\boldsymbol{\mu}_1 - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\mu}_2, \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}).$$

Further, because of this independence, $\mathbf{W} + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\mathbf{X}_2$ given \mathbf{X}_2 is distributed as

$$N_m(\boldsymbol{\mu}_1 - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\mu}_2 + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\mathbf{X}_2, \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}), \quad (3.5.23)$$

which is the desired result. ■

In the following remark, we return to the bivariate normal using the above general notation.

Remark 3.5.1 (Continuation of the Bivariate Normal). Suppose (X, Y) has a $N_2(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, where

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix} \text{ and } \boldsymbol{\Sigma} = \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{12} & \sigma_2^2 \end{bmatrix}. \quad (3.5.24)$$

Substituting $\rho\sigma_1\sigma_2$ for σ_{12} in $\boldsymbol{\Sigma}$, it is easy to see that the determinant of $\boldsymbol{\Sigma}$ is $\sigma_1^2\sigma_2^2(1 - \rho^2)$. Recall that $\rho^2 \leq 1$. For the remainder of this remark, assume that $\rho^2 < 1$. In this case, $\boldsymbol{\Sigma}$ is invertible (it is also positive definite). Further, since $\boldsymbol{\Sigma}$ is a 2×2 matrix, its inverse can easily be determined to be

$$\boldsymbol{\Sigma}^{-1} = \frac{1}{\sigma_1^2\sigma_2^2(1 - \rho^2)} \begin{bmatrix} \sigma_2^2 & -\rho\sigma_1\sigma_2 \\ -\rho\sigma_1\sigma_2 & \sigma_1^2 \end{bmatrix}. \quad (3.5.25)$$

This shows the equivalence of the bivariate normal pdf notation, (3.5.1), and the general multivariate normal distribution with $n = 2$ pdf notation, (3.5.16).

To simplify the conditional normal distribution (3.5.22) for the bivariate case, consider once more the bivariate normal distribution that was given in Section 3.5.1. For this case, reversing the roles so that $Y = X_1$ and $X = X_2$, expression (3.5.22) shows that the conditional distribution of Y given $X = x$ is

$$N \left[\mu_2 + \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1), \sigma_2^2 (1 - \rho^2) \right]. \quad (3.5.26)$$

Thus, with a bivariate normal distribution, the conditional mean of Y , given that $X = x$, is linear in x and is given by

$$E(Y|x) = \mu_2 + \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1).$$

Although the mean of the conditional distribution of Y , given $X = x$, depends upon x (unless $\rho = 0$), the variance $\sigma_2^2(1 - \rho^2)$ is the same for all real values of x . Thus, by way of example, given that $X = x$, the conditional probability that Y is within $(2.576)\sigma_2\sqrt{1 - \rho^2}$ units of the conditional mean is 0.99, whatever the value of x may be. In this sense, most of the probability for the distribution of X and Y lies in the band

$$\mu_2 + \rho \frac{\sigma_2}{\sigma_1} (x - \mu_1) \pm 2.576\sigma_2\sqrt{1 - \rho^2}$$

about the graph of the linear conditional mean. For every fixed positive σ_2 , the width of this band depends upon ρ . Because the band is narrow when ρ^2 is nearly 1, we see that ρ does measure the intensity of the concentration of the probability for X and Y about the linear conditional mean. We alluded to this fact in the remark of Section 2.5.

In a similar manner we can show that the conditional distribution of X , given $Y = y$, is the normal distribution

$$N \left[\mu_1 + \rho \frac{\sigma_1}{\sigma_2} (y - \mu_2), \sigma_1^2 (1 - \rho^2) \right]. \blacksquare$$

Example 3.5.1. Let us assume that in a certain population of married couples the height X_1 of the husband and the height X_2 of the wife have a bivariate normal distribution with parameters $\mu_1 = 5.8$ feet, $\mu_2 = 5.3$ feet, $\sigma_1 = \sigma_2 = 0.2$ foot, and $\rho = 0.6$. The conditional pdf of X_2 , given $X_1 = 6.3$, is normal, with mean $5.3 + (0.6)(6.3 - 5.8) = 5.6$ and standard deviation $(0.2)\sqrt{1 - 0.36} = 0.16$. Accordingly, given that the height of the husband is 6.3 feet, the probability that his wife has a height between 5.28 and 5.92 feet is

$$P(5.28 < X_2 < 5.92 | X_1 = 6.3) = \Phi(2) - \Phi(-2) = 0.954.$$

The interval (5.28, 5.92) could be thought of as a 95.4% *prediction interval* for the wife's height, given $X_1 = 6.3$. ■

3.5.3 *Applications

In this section, we consider several applications of the multivariate normal distribution. These the reader may have already encountered in an applied course in statistics. The first is *principal components*, which results in a linear function of a multivariate normal random vector that has independent components and preserves the “total” variation in the problem.

Let the random vector \mathbf{X} have the multivariate normal distribution $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ where $\boldsymbol{\Sigma}$ is positive definite. As in (3.5.8), write the spectral decomposition of $\boldsymbol{\Sigma}$ as $\boldsymbol{\Sigma} = \boldsymbol{\Gamma}'\boldsymbol{\Lambda}\boldsymbol{\Gamma}$. Recall that the columns, $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$, of $\boldsymbol{\Gamma}'$ are the eigenvectors corresponding to the eigenvalues $\lambda_1, \lambda_2, \dots, \lambda_n$ that form the main diagonal of the matrix $\boldsymbol{\Lambda}$. Assume without loss of generality that the eigenvalues are decreasing; i.e., $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n > 0$. Define the random vector $\mathbf{Y} = \boldsymbol{\Gamma}(\mathbf{X} - \boldsymbol{\mu})$. Since $\boldsymbol{\Gamma}\boldsymbol{\Sigma}\boldsymbol{\Gamma}' = \boldsymbol{\Lambda}$, by Theorem 3.5.2 \mathbf{Y} has a $N_n(\mathbf{0}, \boldsymbol{\Lambda})$ distribution. Hence the components Y_1, Y_2, \dots, Y_n are independent random variables and, for $i = 1, 2, \dots, n$, Y_i has a $N(0, \lambda_i)$ distribution. The random vector \mathbf{Y} is called the vector of **principal components**.

We say the **total variation**, (TV), of a random vector is the sum of the variances of its components. For the random vector \mathbf{X} , because $\boldsymbol{\Gamma}$ is an orthogonal matrix

$$\text{TV}(\mathbf{X}) = \sum_{i=1}^n \sigma_i^2 = \text{tr } \boldsymbol{\Sigma} = \text{tr } \boldsymbol{\Gamma}'\boldsymbol{\Lambda}\boldsymbol{\Gamma} = \text{tr } \boldsymbol{\Lambda}\boldsymbol{\Gamma}\boldsymbol{\Gamma}' = \sum_{i=1}^n \lambda_i = \text{TV}(\mathbf{Y}).$$

Hence, \mathbf{X} and \mathbf{Y} have the same total variation.

Next, consider the first component of \mathbf{Y} , which is given by $Y_1 = \mathbf{v}_1'(\mathbf{X} - \boldsymbol{\mu})$. This is a linear combination of the components of $\mathbf{X} - \boldsymbol{\mu}$ with the property $\|\mathbf{v}_1\|^2 = \sum_{j=1}^n v_{1j}^2 = 1$, because $\boldsymbol{\Gamma}'$ is orthogonal. Consider any other linear combination of $(\mathbf{X} - \boldsymbol{\mu})$, say $\mathbf{a}'(\mathbf{X} - \boldsymbol{\mu})$ such that $\|\mathbf{a}\|^2 = 1$. Because $\mathbf{a} \in R^n$ and $\{\mathbf{v}_1, \dots, \mathbf{v}_n\}$ forms a basis for R^n , we must have $\mathbf{a} = \sum_{j=1}^n a_j \mathbf{v}_j$ for some set of scalars a_1, \dots, a_n . Furthermore, because the basis $\{\mathbf{v}_1, \dots, \mathbf{v}_n\}$ is orthonormal

$$\mathbf{a}'\mathbf{v}_i = \left(\sum_{j=1}^n a_j \mathbf{v}_j \right)' \mathbf{v}_i = \sum_{j=1}^n a_j \mathbf{v}_j' \mathbf{v}_i = a_i.$$

Using (3.5.9) and the fact that $\lambda_i > 0$, we have the inequality

$$\begin{aligned} \text{Var}(\mathbf{a}'\mathbf{X}) &= \mathbf{a}'\boldsymbol{\Sigma}\mathbf{a} \\ &= \sum_{i=1}^n \lambda_i (\mathbf{a}'\mathbf{v}_i)^2 \\ &= \sum_{i=1}^n \lambda_i a_i^2 \leq \lambda_1 \sum_{i=1}^n a_i^2 = \lambda_1 = \text{Var}(Y_1). \end{aligned} \tag{3.5.27}$$

Hence, Y_1 has the maximum variance of any linear combination $\mathbf{a}'(\mathbf{X} - \boldsymbol{\mu})$, such that $\|\mathbf{a}\| = 1$. For this reason, Y_1 is called the **first principal component** of \mathbf{X} .

What about the other components, Y_2, \dots, Y_n ? As the following theorem shows, they share a similar property relative to the order of their associated eigenvalue. For this reason, they are called the **second**, **third**, through the **n th principal components**, respectively.

Theorem 3.5.5. *Consider the situation described above. For $j = 2, \dots, n$ and $i = 1, 2, \dots, j - 1$, $\text{Var}[\mathbf{a}' \mathbf{X}] \leq \lambda_j = \text{Var}(Y_j)$, for all vectors \mathbf{a} such that $\mathbf{a} \perp \mathbf{v}_i$ and $\|\mathbf{a}\| = 1$.*

The proof of this theorem is similar to that for the first principal component and is left as Exercise 3.5.20. A second application concerning linear regression is offered in Exercise 3.5.22.

EXERCISES

3.5.1. Let X and Y have a bivariate normal distribution with respective parameters $\mu_x = 2.8$, $\mu_y = 110$, $\sigma_x^2 = 0.16$, $\sigma_y^2 = 100$, and $\rho = 0.6$. Using R, compute:

- (a) $P(106 < Y < 124)$.
- (b) $P(106 < Y < 124 | X = 3.2)$.

3.5.2. Let X and Y have a bivariate normal distribution with parameters $\mu_1 = 3$, $\mu_2 = 1$, $\sigma_1^2 = 16$, $\sigma_2^2 = 25$, and $\rho = \frac{3}{5}$. Using R, determine the following probabilities:

- (a) $P(3 < Y < 8)$.
- (b) $P(3 < Y < 8 | X = 7)$.
- (c) $P(-3 < X < 3)$.
- (d) $P(-3 < X < 3 | Y = -4)$.

3.5.3. Show that expression (3.5.4) is true.

3.5.4. Let $f(x, y)$ be the bivariate normal pdf in expression (3.5.1).

- (a) Show that $f(x, y)$ has an unique maximum at (μ_1, μ_2) .
- (b) For a given $c > 0$, show that the points $\{(x, y) : f(x, y) = c\}$ of equal probability form an ellipse.

3.5.5. Let \mathbf{X} be $N_2(\boldsymbol{\mu}, \boldsymbol{\Sigma})$. Recall expression (3.5.17) which gives the probability of an elliptical contour region for \mathbf{X} . The R function⁸ `ellipmake` plots the elliptical contour regions. To graph the elliptical 95% contour for a multivariate normal distribution with $\boldsymbol{\mu} = (5, 2)'$ and $\boldsymbol{\Sigma}$ with variances 1 and covariance 0.75, use the code

⁸Part of this code was obtained from an anonymous author at the site <http://stats.stackexchange.com/questions/9898/>

```
ellipmake(p=.95,b=matrix(c(1,.75,.75,1),nrow=2),mu=c(5,2)).
```

This R function can be found at the site listed in the Preface.

- (a) Run the above code.
- (b) Change the code so the probability is 0.50.
- (c) Change the code to obtain an overlay plot of the 0.50 and 0.95 regions.
- (d) Using a loop, obtain the overlay plot for a vector of probabilities.

3.5.6. Let U and V be independent random variables, each having a standard normal distribution. Show that the mgf $E(e^{t(UV)})$ of the random variable UV is $(1-t^2)^{-1/2}$, $-1 < t < 1$.

Hint: Compare $E(e^{tUV})$ with the integral of a bivariate normal pdf that has means equal to zero.

3.5.7. Let X and Y have a bivariate normal distribution with parameters $\mu_1 = 5$, $\mu_2 = 10$, $\sigma_1^2 = 1$, $\sigma_2^2 = 25$, and $\rho > 0$. If $P(4 < Y < 16|X = 5) = 0.954$, determine ρ .

3.5.8. Let X and Y have a bivariate normal distribution with parameters $\mu_1 = 20$, $\mu_2 = 40$, $\sigma_1^2 = 9$, $\sigma_2^2 = 4$, and $\rho = 0.6$. Find the shortest interval for which 0.90 is the conditional probability that Y is in the interval, given that $X = 22$.

3.5.9. Say the correlation coefficient between the heights of husbands and wives is 0.70 and the mean male height is 5 feet 10 inches with standard deviation 2 inches, and the mean female height is 5 feet 4 inches with standard deviation $1\frac{1}{2}$ inches. Assuming a bivariate normal distribution, what is the best guess of the height of a woman whose husband's height is 6 feet? Find a 95% prediction interval for her height.

3.5.10. Let

$$f(x, y) = (1/2\pi) \exp \left[-\frac{1}{2}(x^2 + y^2) \right] \left\{ 1 + xy \exp \left[-\frac{1}{2}(x^2 + y^2 - 2) \right] \right\},$$

where $-\infty < x < \infty$, $-\infty < y < \infty$. If $f(x, y)$ is a joint pdf, it is not a normal bivariate pdf. Show that $f(x, y)$ actually is a joint pdf and that each marginal pdf is normal. Thus the fact that each marginal pdf is normal does not imply that the joint pdf is bivariate normal.

3.5.11. Let X , Y , and Z have the joint pdf

$$\left(\frac{1}{2\pi} \right)^{3/2} \exp \left(-\frac{x^2 + y^2 + z^2}{2} \right) \left[1 + xyz \exp \left(-\frac{x^2 + y^2 + z^2}{2} \right) \right],$$

where $-\infty < x < \infty$, $-\infty < y < \infty$, and $-\infty < z < \infty$. While X , Y , and Z are obviously dependent, show that X , Y , and Z are pairwise independent and that each pair has a bivariate normal distribution.

3.5.12. Let X and Y have a bivariate normal distribution with parameters $\mu_1 = \mu_2 = 0$, $\sigma_1^2 = \sigma_2^2 = 1$, and correlation coefficient ρ . Find the distribution of the random variable $Z = aX + bY$ in which a and b are nonzero constants.

3.5.13. Establish formula (3.5.11) by a direct multiplication.

3.5.14. Let $\mathbf{X} = (X_1, X_2, X_3)$ have a multivariate normal distribution with mean vector $\mathbf{0}$ and variance-covariance matrix

$$\Sigma = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 1 \\ 0 & 1 & 2 \end{bmatrix}.$$

Find $P(X_1 > X_2 + X_3 + 2)$.

Hint: Find the vector \mathbf{a} so that $\mathbf{a}\mathbf{X} = X_1 - X_2 - X_3$ and make use of Theorem 3.5.2.

3.5.15. Suppose \mathbf{X} is distributed $N_n(\boldsymbol{\mu}, \Sigma)$. Let $\bar{X} = n^{-1} \sum_{i=1}^n X_i$.

- (a) Write \bar{X} as $\mathbf{a}\mathbf{X}$ for an appropriate vector \mathbf{a} and apply Theorem 3.5.2 to find the distribution of \bar{X} .
- (b) Determine the distribution of \bar{X} if all of its component random variables X_i have the same mean μ .

3.5.16. Suppose \mathbf{X} is distributed $N_2(\boldsymbol{\mu}, \Sigma)$. Determine the distribution of the random vector $(X_1 + X_2, X_1 - X_2)$. Show that $X_1 + X_2$ and $X_1 - X_2$ are independent if $\text{Var}(X_1) = \text{Var}(X_2)$.

3.5.17. Suppose \mathbf{X} is distributed $N_3(\mathbf{0}, \Sigma)$, where

$$\Sigma = \begin{bmatrix} 3 & 2 & 1 \\ 2 & 2 & 1 \\ 1 & 1 & 3 \end{bmatrix}.$$

Find $P((X_1 - 2X_2 + X_3)^2 > 15.36)$.

3.5.18. Let X_1, X_2, X_3 be iid random variables each having a standard normal distribution. Let the random variables Y_1, Y_2, Y_3 be defined by

$$X_1 = Y_1 \cos Y_2 \sin Y_3, \quad X_2 = Y_1 \sin Y_2 \sin Y_3, \quad X_3 = Y_1 \cos Y_3,$$

where $0 \leq Y_1 < \infty$, $0 \leq Y_2 < 2\pi$, $0 \leq Y_3 \leq \pi$. Show that Y_1, Y_2, Y_3 are mutually independent.

3.5.19. Show that expression (3.5.9) is true.

3.5.20. Prove Theorem 3.5.5.

3.5.21. Suppose \mathbf{X} has a multivariate normal distribution with mean $\mathbf{0}$ and covariance matrix

$$\Sigma = \begin{bmatrix} 283 & 215 & 277 & 208 \\ 215 & 213 & 217 & 153 \\ 277 & 217 & 336 & 236 \\ 208 & 153 & 236 & 194 \end{bmatrix}.$$

- (a) Find the total variation of \mathbf{X} .
- (b) Find the principal component vector \mathbf{Y} .
- (c) Show that the first principal component accounts for 90% of the total variation.
- (d) Show that the first principal component Y_1 is essentially a rescaled $\overline{\mathbf{X}}$. Determine the variance of $(1/2)\overline{\mathbf{X}}$ and compare it to that of Y_1 .

Note that the R command `eigen(amat)` obtains the spectral decomposition of the matrix `amat`.

3.5.22. Readers may have encountered the multiple regression model in a previous course in statistics. We can briefly write it as follows. Suppose we have a vector of n observations \mathbf{Y} which has the distribution $N_n(\mathbf{X}\boldsymbol{\beta}, \sigma^2\mathbf{I})$, where \mathbf{X} is an $n \times p$ matrix of known values, which has full column rank p , and $\boldsymbol{\beta}$ is a $p \times 1$ vector of unknown parameters. The least squares estimator of $\boldsymbol{\beta}$ is

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}.$$

- (a) Determine the distribution of $\hat{\boldsymbol{\beta}}$.
- (b) Let $\hat{\mathbf{Y}} = \mathbf{X}\hat{\boldsymbol{\beta}}$. Determine the distribution of $\hat{\mathbf{Y}}$.
- (c) Let $\hat{\mathbf{e}} = \mathbf{Y} - \hat{\mathbf{Y}}$. Determine the distribution of $\hat{\mathbf{e}}$.
- (d) By writing the random vector $(\hat{\mathbf{Y}}', \hat{\mathbf{e}}')'$ as a linear function of \mathbf{Y} , show that the random vectors $\hat{\mathbf{Y}}$ and $\hat{\mathbf{e}}$ are independent.
- (e) Show that $\hat{\boldsymbol{\beta}}$ solves the least squares problem; that is,

$$\|\mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}}\|^2 = \min_{\mathbf{b} \in R^p} \|\mathbf{Y} - \mathbf{X}\mathbf{b}\|^2.$$

3.6 *t-* and *F*-Distributions

It is the purpose of this section to define two additional distributions that are quite useful in certain problems of statistical inference. These are called, respectively, the (Student's) *t*-distribution and the *F*-distribution.

3.6.1 The *t*-distribution

Let W denote a random variable that is $N(0, 1)$; let V denote a random variable that is $\chi^2(r)$; and let W and V be independent. Then the joint pdf of W and V , say $h(w, v)$, is the product of the pdf of W and that of V or

$$h(w, v) = \begin{cases} \frac{1}{\sqrt{2\pi}} e^{-w^2/2} \frac{1}{\Gamma(r/2)2^{r/2}} v^{r/2-1} e^{-v/2} & -\infty < w < \infty, \quad 0 < v < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Define a new random variable T by writing

$$T = \frac{W}{\sqrt{V/r}}. \quad (3.6.1)$$

The transformation technique is used to obtain the pdf $g_1(t)$ of T . The equations

$$t = \frac{w}{\sqrt{v/r}} \quad \text{and} \quad u = v$$

define a transformation that maps $\mathcal{S} = \{(w, v) : -\infty < w < \infty, 0 < v < \infty\}$ one-to-one and onto $\mathcal{T} = \{(t, u) : -\infty < t < \infty, 0 < u < \infty\}$. Since $w = t\sqrt{u}/\sqrt{r}$, $v = u$, the absolute value of the Jacobian of the transformation is $|J| = \sqrt{u}/\sqrt{r}$. Accordingly, the joint pdf of T and $U = V$ is given by

$$\begin{aligned} g(t, u) &= h\left(\frac{t\sqrt{u}}{\sqrt{r}}, u\right)|J| \\ &= \begin{cases} \frac{1}{\sqrt{2\pi}\Gamma(r/2)2^{r/2}}u^{r/2-1}\exp\left[-\frac{u}{2}\left(1+\frac{t^2}{r}\right)\right]\frac{\sqrt{u}}{\sqrt{r}} & |t| < \infty, 0 < u < \infty \\ 0 & \text{elsewhere.} \end{cases} \end{aligned}$$

The marginal pdf of T is then

$$\begin{aligned} g_1(t) &= \int_{-\infty}^{\infty} g(t, u) du \\ &= \int_0^{\infty} \frac{1}{\sqrt{2\pi r}\Gamma(r/2)2^{r/2}}u^{(r+1)/2-1}\exp\left[-\frac{u}{2}\left(1+\frac{t^2}{r}\right)\right] du. \end{aligned}$$

In this integral let $z = u[1 + (t^2/r)]/2$, and it is seen that

$$\begin{aligned} g_1(t) &= \int_0^{\infty} \frac{1}{\sqrt{2\pi r}\Gamma(r/2)2^{r/2}}\left(\frac{2z}{1+t^2/r}\right)^{(r+1)/2-1}e^{-z}\left(\frac{2}{1+t^2/r}\right) dz \\ &= \frac{\Gamma[(r+1)/2]}{\sqrt{\pi r}\Gamma(r/2)}\frac{1}{(1+t^2/r)^{(r+1)/2}}, \quad -\infty < t < \infty. \end{aligned} \quad (3.6.2)$$

Thus, if W is $N(0, 1)$, V is $\chi^2(r)$, and W and V are independent, then $T = W/\sqrt{V/r}$ has the pdf $g_1(t)$, (3.6.2). The distribution of the random variable T is usually called a ***t*-distribution**. It should be observed that a *t*-distribution is completely determined by the parameter r , the number of degrees of freedom of the random variable that has the chi-square distribution.

The pdf $g_1(t)$ satisfies $g_1(-t) = g_1(t)$; hence, the pdf of T is symmetric about 0. Thus, the median of T is 0. Upon differentiating $g_1(t)$, it follows that the unique maximum of the pdf occurs at 0 and that the derivative is continuous. So, the pdf is mound shaped. As the degrees of freedom approach ∞ , the *t*-distribution converges to the $N(0, 1)$ distribution; see Example 5.2.3 of Chapter 5.

The R command `pt(t, r)` computes the probability $P(T \leq t)$ when T has a *t*-distribution with r degrees of freedom. For instance, the probability that a *t*-distributed random variable with 15 degrees of freedom is less than 2.0 is computed

as `pt(2.0,15)`, while the command `qt(.975,15)` returns the 97.5th percentile of this distribution. The R code `t=seq(-4,4,.01)` followed by `plot(dt(t,3)^t)` yields a plot of the t -pdf with 3 degrees of freedom.

Before the age of modern computing, tables of the distribution of T were used. Because the pdf of T does depend on its degrees of freedom r , the usual t -table gives selected quantiles versus degrees of freedom. Table III in Appendix D is such a table. The following three lines of R code, however, produce this table.

```
ps = c(.9,.925,.950,.975,.99,.995,.999); df = 1:30; tab=c()
for(r in df){tab=rbind(tab,qt(ps,r))}; df=c(df,Inf);nq=qnorm(ps)
tab=rbind(tab,nq);tab=cbind(df,tab)
```

This code is the body of the R function `ttable` found at the site listed in the Preface. Due to the fact that t -distribution converges to the $N(0,1)$ distribution, only the degrees of freedom from 1 to 30 are used in such tables. This is, also, the reason that the last line in the table are the standard normal quantiles.

Remark 3.6.1. The t -distribution was first discovered by W. S. Gosset when he was working for an Irish brewery. Gosset published under the pseudonym Student. Thus this distribution is often known as **Student's t -distribution**. ■

Example 3.6.1 (Mean and Variance of the t -Distribution). Let the random variable T have a t -distribution with r degrees of freedom. Then, as in (3.6.1), we can write $T = W(V/r)^{-1/2}$, where W has a $N(0,1)$ distribution, V has a $\chi^2(r)$ distribution, and W and V are independent random variables. Independence of W and V and expression (3.3.8), provided $(r/2) - (k/2) > 0$ (i.e., $k < r$), implies the following:

$$E(T^k) = E\left[W^k \left(\frac{V}{r}\right)^{-k/2}\right] = E(W^k)E\left[\left(\frac{V}{r}\right)^{-k/2}\right] \quad (3.6.3)$$

$$= E(W^k) \frac{2^{-k/2} \Gamma\left(\frac{r}{2} - \frac{k}{2}\right)}{\Gamma\left(\frac{r}{2}\right) r^{-k/2}} \quad \text{if } k < r. \quad (3.6.4)$$

Because $E(W) = 0$, the mean of T is 0, as long as the degrees of freedom of T exceed 1. For the variance, use $k = 2$ in expression (3.6.4). In this case the condition $r > k$ becomes $r > 2$. Since $E(W^2) = 1$, by expression (3.6.4), the variance of T is given by

$$\text{Var}(T) = E(T^2) = \frac{r}{r-2}. \quad (3.6.5)$$

Therefore, a t -distribution with $r > 2$ degrees of freedom has a mean of 0 and a variance of $r/(r-2)$. ■

3.6.2 The F -distribution

Next consider two independent chi-square random variables U and V having r_1 and r_2 degrees of freedom, respectively. The joint pdf $h(u,v)$ of U and V is then

$$h(u,v) = \begin{cases} \frac{1}{\Gamma(r_1/2)\Gamma(r_2/2)^{(r_1+r_2)/2}} u^{r_1/2-1} v^{r_2/2-1} e^{-(u+v)/2} & 0 < u, v < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

We define the new random variable

$$W = \frac{U/r_1}{V/r_2}$$

and we propose finding the pdf $g_1(w)$ of W . The equations

$$w = \frac{u/r_1}{v/r_2}, \quad z = v,$$

define a one-to-one transformation that maps the set $\mathcal{S} = \{(u, v) : 0 < u < \infty, 0 < v < \infty\}$ onto the set $\mathcal{T} = \{(w, z) : 0 < w < \infty, 0 < z < \infty\}$. Since $u = (r_1/r_2)zw$, $v = z$, the absolute value of the Jacobian of the transformation is $|J| = (r_1/r_2)z$. The joint pdf $g(w, z)$ of the random variables W and $Z = V$ is then

$$g(w, z) = \frac{1}{\Gamma(r_1/2)\Gamma(r_2/2)2^{(r_1+r_2)/2}} \left(\frac{r_1 zw}{r_2}\right)^{\frac{r_1-2}{2}} z^{\frac{r_2-2}{2}} \exp\left[-\frac{z}{2}\left(\frac{r_1 w}{r_2} + 1\right)\right] \frac{r_1 z}{r_2},$$

provided that $(w, z) \in \mathcal{T}$, and zero elsewhere. The marginal pdf $g_1(w)$ of W is then

$$\begin{aligned} g_1(w) &= \int_{-\infty}^{\infty} g(w, z) dz \\ &= \int_0^{\infty} \frac{(r_1/r_2)^{r_1/2}(w)^{r_1/2-1}}{\Gamma(r_1/2)\Gamma(r_2/2)2^{(r_1+r_2)/2}} z^{(r_1+r_2)/2-1} \exp\left[-\frac{z}{2}\left(\frac{r_1 w}{r_2} + 1\right)\right] dz. \end{aligned}$$

If we change the variable of integration by writing

$$y = \frac{z}{2} \left(\frac{r_1 w}{r_2} + 1\right),$$

it can be seen that

$$\begin{aligned} g_1(w) &= \int_0^{\infty} \frac{(r_1/r_2)^{r_1/2}(w)^{r_1/2-1}}{\Gamma(r_1/2)\Gamma(r_2/2)2^{(r_1+r_2)/2}} \left(\frac{2y}{r_1 w/r_2 + 1}\right)^{(r_1+r_2)/2-1} e^{-y} \\ &\quad \times \left(\frac{2}{r_1 w/r_2 + 1}\right) dy \\ &= \begin{cases} \frac{\Gamma[(r_1+r_2)/2](r_1/r_2)^{r_1/2}}{\Gamma(r_1/2)\Gamma(r_2/2)} \frac{w^{r_1/2-1}}{(1+r_1 w/r_2)^{(r_1+r_2)/2}} & 0 < w < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (3.6.6) \end{aligned}$$

Accordingly, if U and V are independent chi-square variables with r_1 and r_2 degrees of freedom, respectively, then $W = (U/r_1)/(V/r_2)$ has the pdf $g_1(w)$, (3.6.6). The distribution of this random variable is usually called an ***F*-distribution**; and we often call the ratio, which we have denoted by W , F . That is,

$$F = \frac{U/r_1}{V/r_2}. \quad (3.6.7)$$

It should be observed that an *F*-distribution is completely determined by the two parameters r_1 and r_2 .

In terms of R computation, the command `pf(2.50,3,8)` computes to the value 0.8665 which is the probability $P(F \leq 2.50)$ when F has the F -distribution with 3 and 8 degrees of freedom. The 95th percentile of F is `qf(.95,3,8) = 4.066` and the code `x=seq(.01,5,.01);plot(df(x,3,8)^x)` draws a plot of the pdf of this F random variable. Note that the pdf is right-skewed. Before the age of modern computation, tables of the quantiles of F -distributions for selected probabilities and degrees of freedom were used. Table IV in Appendix D displays the 95th and 99th quantiles for selected degrees of freedom. Besides its use in statistics, the F -distribution is used to model lifetime data; see Exercise 3.6.13.

Example 3.6.2 (Moments of F -Distributions). Let F have an F -distribution with r_1 and r_2 degrees of freedom. Then, as in expression (3.6.7), we can write $F = (r_2/r_1)(U/V)$, where U and V are independent χ^2 random variables with r_1 and r_2 degrees of freedom, respectively. Hence, for the k th moment of F , by independence we have

$$E(F^k) = \left(\frac{r_2}{r_1}\right)^k E(U^k) E(V^{-k}),$$

provided, of course, that both expectations on the right side exist. By Theorem 3.3.2, because $k > -(r_1/2)$ is always true, the first expectation always exists. The second expectation, however, exists if $r_2 > 2k$; i.e., the denominator degrees of freedom must exceed twice k . Assuming this is true, it follows from (3.3.8) that the mean of F is given by

$$E(F) = \frac{r_2}{r_1} r_1 \frac{2^{-1} \Gamma\left(\frac{r_2}{2} - 1\right)}{\Gamma\left(\frac{r_2}{2}\right)} = \frac{r_2}{r_2 - 2}. \quad (3.6.8)$$

If r_2 is large, then $E(F)$ is about 1. In Exercise 3.6.7, a general expression for $E(F^k)$ is derived. ■

3.6.3 Student's Theorem

Our final note in this section concerns an important result for the later chapters on inference for normal random variables. It is a corollary to the t -distribution derived above and is often referred to as Student's Theorem.

Theorem 3.6.1. *Let X_1, \dots, X_n be iid random variables each having a normal distribution with mean μ and variance σ^2 . Define the random variables*

$$\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i \text{ and } S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2.$$

Then

- (a) \bar{X} has a $N\left(\mu, \frac{\sigma^2}{n}\right)$ distribution.
- (b) \bar{X} and S^2 are independent.
- (c) $(n-1)S^2/\sigma^2$ has a $\chi^2(n-1)$ distribution.

(d) *The random variable*

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}} \quad (3.6.9)$$

*has a Student *t*-distribution with $n - 1$ degrees of freedom.*

Proof: Note that we have proved part (a) in Corollary 3.4.1. Let $\mathbf{X} = (X_1, \dots, X_n)'$. Because X_1, \dots, X_n are iid $N(\mu, \sigma^2)$ random variables, \mathbf{X} has a multivariate normal distribution $N(\mu\mathbf{1}, \sigma^2\mathbf{I})$, where $\mathbf{1}$ denotes a vector whose components are all 1. Let $\mathbf{v}' = (1/n, \dots, 1/n) = (1/n)\mathbf{1}'$. Note that $\bar{X} = \mathbf{v}'\mathbf{X}$. Define the random vector \mathbf{Y} by $\mathbf{Y} = (X_1 - \bar{X}, \dots, X_n - \bar{X})'$. Consider the following transformation:

$$\mathbf{W} = \begin{bmatrix} \bar{X} \\ \mathbf{Y} \end{bmatrix} = \begin{bmatrix} \mathbf{v}' \\ \mathbf{I} - \mathbf{1}\mathbf{v}' \end{bmatrix} \mathbf{X}. \quad (3.6.10)$$

Because \mathbf{W} is a linear transformation of multivariate normal random vector, by Theorem 3.5.2 it has a multivariate normal distribution with mean

$$E[\mathbf{W}] = \begin{bmatrix} \mathbf{v}' \\ \mathbf{I} - \mathbf{1}\mathbf{v}' \end{bmatrix} \mu\mathbf{1} = \begin{bmatrix} \mu \\ \mathbf{0}_n \end{bmatrix}, \quad (3.6.11)$$

where $\mathbf{0}_n$ denotes a vector whose components are all 0, and covariance matrix

$$\begin{aligned} \Sigma &= \begin{bmatrix} \mathbf{v}' \\ \mathbf{I} - \mathbf{1}\mathbf{v}' \end{bmatrix} \sigma^2 \mathbf{I} \begin{bmatrix} \mathbf{v}' \\ \mathbf{I} - \mathbf{1}\mathbf{v}' \end{bmatrix}' \\ &= \sigma^2 \begin{bmatrix} \frac{1}{n} & \mathbf{0}'_n \\ \mathbf{0}_n & \mathbf{I} - \mathbf{1}\mathbf{v}' \end{bmatrix}. \end{aligned} \quad (3.6.12)$$

Because \bar{X} is the first component of \mathbf{W} , we can also obtain part (a) by Theorem 3.5.1. Next, because the covariances are 0, \bar{X} is independent of \mathbf{Y} . But $S^2 = (n-1)^{-1}\mathbf{Y}'\mathbf{Y}$. Hence, \bar{X} is independent of S^2 , also. Thus part (b) is true.

Consider the random variable

$$V = \sum_{i=1}^n \left(\frac{X_i - \mu}{\sigma} \right)^2.$$

Each term in this sum is the square of a $N(0, 1)$ random variable and, hence, has a $\chi^2(1)$ distribution (Theorem 3.4.1). Because the summands are independent, it follows from Corollary 3.3.1 that V is a $\chi^2(n)$ random variable. Note the following identity:

$$\begin{aligned} V &= \sum_{i=1}^n \left(\frac{(X_i - \bar{X}) + (\bar{X} - \mu)}{\sigma} \right)^2 \\ &= \sum_{i=1}^n \left(\frac{X_i - \bar{X}}{\sigma} \right)^2 + \left(\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \right)^2 \\ &= \frac{(n-1)S^2}{\sigma^2} + \left(\frac{\bar{X} - \mu}{\sigma/\sqrt{n}} \right)^2. \end{aligned} \quad (3.6.13)$$

By part (b), the two terms on the right side of the last equation are independent. Further, the second term is the square of a standard normal random variable and, hence, has a $\chi^2(1)$ distribution. Taking mgfs of both sides, we have

$$(1 - 2t)^{-n/2} = E[\exp\{t(n-1)S^2/\sigma^2\}] (1 - 2t)^{-1/2}. \quad (3.6.14)$$

Solving for the mgf of $(n-1)S^2/\sigma^2$ on the right side we obtain part (c). Finally, part (d) follows immediately from parts (a)–(c) upon writing T , (3.6.9), as

$$T = \frac{(\bar{X} - \mu)/(\sigma/\sqrt{n})}{\sqrt{(n-1)S^2/(\sigma^2(n-1))}}. \blacksquare$$

EXERCISES

3.6.1. Let T have a t -distribution with 10 degrees of freedom. Find $P(|T| > 2.228)$ from either Table III or by using R.

3.6.2. Let T have a t -distribution with 14 degrees of freedom. Determine b so that $P(-b < T < b) = 0.90$. Use either Table III or by using R.

3.6.3. Let T have a t -distribution with $r > 4$ degrees of freedom. Use expression (3.6.4) to determine the kurtosis of T . See Exercise 1.9.15 for the definition of kurtosis.

3.6.4. Using R, plot the pdfs of the random variables defined in parts (a)–(e) below. Obtain an overlay plot of all five pdfs, also.

(a) X has a standard normal distribution. Use this code:

```
x=seq(-6,6,.01); plot(dnorm(x)^x).
```

(b) X has a t -distribution with 1 degree of freedom. Use the code:

```
lines(dt(x,1)^x, lty=2).
```

(c) X has a t -distribution with 3 degrees of freedom.

(d) X has a t -distribution with 10 degrees of freedom.

(e) X has a t -distribution with 30 degrees of freedom.

3.6.5. Using R, investigate the probabilities of an “outlier” for a t -random variable and a normal random variable. Specifically, determine the probability of observing the event $\{|X| \geq 2\}$ for the following random variables:

(a) X has a standard normal distribution.

(b) X has a t -distribution with 1 degree of freedom.

(c) X has a t -distribution with 3 degrees of freedom.

(d) X has a t -distribution with 10 degrees of freedom.

- (e) X has a *t*-distribution with 30 degrees of freedom.

3.6.6. In expression (3.4.13), the normal location model was presented. Often real data, though, have more outliers than the normal distribution allows. Based on Exercise 3.6.5, outliers are more probable for *t*-distributions with small degrees of freedom. Consider a location model of the form

$$X = \mu + e,$$

where e has a *t*-distribution with 3 degrees of freedom. Determine the standard deviation σ of X and then find $P(|X - \mu| \geq \sigma)$.

3.6.7. Let F have an *F*-distribution with parameters r_1 and r_2 . Assuming that $r_2 > 2k$, continue with Example 3.6.2 and derive the $E(F^k)$.

3.6.8. Let F have an *F*-distribution with parameters r_1 and r_2 . Using the results of the last exercise, determine the kurtosis of F , assuming that $r_2 > 8$.

3.6.9. Let F have an *F*-distribution with parameters r_1 and r_2 . Argue that $1/F$ has an *F*-distribution with parameters r_2 and r_1 .

3.6.10. Suppose F has an *F*-distribution with parameters $r_1 = 5$ and $r_2 = 10$. Using only 95th percentiles of *F*-distributions, find a and b so that $P(F \leq a) = 0.05$ and $P(F \leq b) = 0.95$, and, accordingly, $P(a < F < b) = 0.90$.

Hint: Write $P(F \leq a) = P(1/F \geq 1/a) = 1 - P(1/F \leq 1/a)$, and use the result of Exercise 3.6.9 and R.

3.6.11. Let $T = W/\sqrt{V/r}$, where the independent variables W and V are, respectively, normal with mean zero and variance 1 and chi-square with r degrees of freedom. Show that T^2 has an *F*-distribution with parameters $r_1 = 1$ and $r_2 = r$.

Hint: What is the distribution of the numerator of T^2 ?

3.6.12. Show that the *t*-distribution with $r = 1$ degree of freedom and the Cauchy distribution are the same.

3.6.13. Let F have an *F*-distribution with $2r$ and $2s$ degrees of freedom. Since the support of F is $(0, \infty)$, the *F*-distribution is often used to model time until failure (lifetime). In this case, $Y = \log F$ is used to model the log of lifetime. The $\log F$ family is a rich family of distributions consisting of left- and right-skewed distributions as well as symmetric distributions; see, for example, Chapter 4 of Hettmansperger and McKean (2011). In this exercise, consider the subfamily where $Y = \log F$ and F has 2 and $2s$ degrees of freedom.

- (a) Obtain the pdf and cdf of Y .
- (b) Using R, obtain a page of plots of these distributions for $s = .4, .6, 1.0, 2.0, 4.0, 8$. Comment on the shape of each pdf.
- (c) For $s = 1$, this distribution is called the **logistic** distribution. Show that the pdf is symmetric about 0.

3.6.14. Show that

$$Y = \frac{1}{1 + (r_1/r_2)W},$$

where W has an F -distribution with parameters r_1 and r_2 , has a beta distribution.

3.6.15. Let X_1, X_2 be iid with common distribution having the pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Show that $Z = X_1/X_2$ has an F -distribution.

3.6.16. Let X_1, X_2 , and X_3 be three independent chi-square variables with r_1, r_2 , and r_3 degrees of freedom, respectively.

(a) Show that $Y_1 = X_1/X_2$ and $Y_2 = X_1 + X_2$ are independent and that Y_2 is $\chi^2(r_1 + r_2)$.

(b) Deduce that

$$\frac{X_1/r_1}{X_2/r_2} \quad \text{and} \quad \frac{X_3/r_3}{(X_1 + X_2)/(r_1 + r_2)}$$

are independent F -variables.

3.7 *Mixture Distributions

Recall the discussion on the contaminated normal distribution given in Section 3.4.1. This was an example of a mixture of normal distributions. In this section, we extend this to mixtures of distributions in general. Generally, we use continuous-type notation for the discussion, but discrete pmfs can be handled the same way.

Suppose that we have k distributions with respective pdfs $f_1(x), f_2(x), \dots, f_k(x)$, with supports $\mathcal{S}_1, \mathcal{S}_2, \dots, \mathcal{S}_k$, means $\mu_1, \mu_2, \dots, \mu_k$, and variances $\sigma_1^2, \sigma_2^2, \dots, \sigma_k^2$, with positive mixing probabilities p_1, p_2, \dots, p_k , where $p_1 + p_2 + \dots + p_k = 1$. Let $\mathcal{S} = \cup_{i=1}^k \mathcal{S}_i$ and consider the function

$$f(x) = p_1 f_1(x) + p_2 f_2(x) + \dots + p_k f_k(x) = \sum_{i=1}^k p_i f_i(x), \quad x \in \mathcal{S}. \quad (3.7.1)$$

Note that $f(x)$ is nonnegative and it is easy to see that it integrates to one over $(-\infty, \infty)$; hence, $f(x)$ is a pdf for some continuous-type random variable X . Integrating term-by-term, it follows that the cdf of X is:

$$F(x) = \sum_{i=1}^k p_i F_i(x), \quad x \in \mathcal{S}, \quad (3.7.2)$$

where $F_i(x)$ is the cdf corresponding to the pdf $f_i(x)$. The mean of X is given by

$$E(X) = \sum_{i=1}^k p_i \int_{-\infty}^{\infty} x f_i(x) dx = \sum_{i=1}^k p_i \mu_i = \bar{\mu}, \quad (3.7.3)$$

a weighted average of $\mu_1, \mu_2, \dots, \mu_k$, and the variance equals

$$\begin{aligned}\text{var}(X) &= \sum_{i=1}^k p_i \int_{-\infty}^{\infty} (x - \bar{\mu})^2 f_i(x) dx \\ &= \sum_{i=1}^k p_i \int_{-\infty}^{\infty} [(x - \mu_i) + (\mu_i - \bar{\mu})]^2 f_i(x) dx \\ &= \sum_{i=1}^k p_i \int_{-\infty}^{\infty} (x - \mu_i)^2 f_i(x) dx + \sum_{i=1}^k p_i (\mu_i - \bar{\mu})^2 \int_{-\infty}^{\infty} f_i(x) dx,\end{aligned}$$

because the cross-product terms integrate to zero. That is,

$$\text{var}(X) = \sum_{i=1}^k p_i \sigma_i^2 + \sum_{i=1}^k p_i (\mu_i - \bar{\mu})^2. \quad (3.7.4)$$

Note that the variance is not simply the weighted average of the k variances, but it also includes a positive term involving the weighted variance of the means.

Remark 3.7.1. It is extremely important to note these characteristics are associated with a mixture of k distributions and have nothing to do with a linear combination, say $\sum a_i X_i$, of k random variables. ■

For the next example, we need the following distribution. We say that X has a **loggamma** pdf with parameters $\alpha > 0$ and $\beta > 0$ if it has pdf

$$f_1(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{-(1+\beta)/\beta} (\log x)^{\alpha-1} & x > 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (3.7.5)$$

The derivation of this pdf is given in Exercise 3.7.1, where its mean and variance are also derived. We denote this distribution of X by $\log\Gamma(\alpha, \beta)$.

Example 3.7.1. Actuaries have found that a mixture of the loggamma and gamma distributions is an important model for claim distributions. Suppose, then, that X_1 is $\log\Gamma(\alpha_1, \beta_1)$, X_2 is $\Gamma(\alpha_2, \beta_2)$, and the mixing probabilities are p and $(1 - p)$. Then the pdf of the mixture distribution is

$$f(x) = \begin{cases} \frac{1-p}{\beta_2^{\alpha_2} \Gamma(\alpha_2)} x^{\alpha_2-1} e^{-x/\beta_2} & 0 < x \leq 1 \\ \frac{p}{\beta_1^{\alpha_1} \Gamma(\alpha_1)} (\log x)^{\alpha_1-1} x^{-(\beta_1+1)/\beta_1} + \frac{1-p}{\beta_2^{\alpha_2} \Gamma(\alpha_2)} x^{\alpha_2-1} e^{-x/\beta_2} & 1 < x \\ 0 & \text{elsewhere.} \end{cases} \quad (3.7.6)$$

Provided $\beta_1 < 2^{-1}$, the mean and the variance of this mixture distribution are

$$\mu = p(1 - \beta_1)^{-\alpha_1} + (1 - p)\alpha_2\beta_2 \quad (3.7.7)$$

$$\begin{aligned}\sigma^2 &= p[(1 - 2\beta_1)^{-\alpha_1} - (1 - \beta_1)^{-2\alpha_1}] \\ &\quad + (1 - p)\alpha_2\beta_2^2 + p(1 - p)[(1 - \beta_1)^{-\alpha_1} - \alpha_2\beta_2]^2;\end{aligned} \quad (3.7.8)$$

see Exercise 3.7.3. ■

The mixture of distributions is sometimes called **compounding**. Moreover, it does not need to be restricted to a finite number of distributions. As demonstrated in the following example, a continuous weighting function, which is of course a pdf, can replace p_1, p_2, \dots, p_k ; i.e., integration replaces summation.

Example 3.7.2. Let X_θ be a Poisson random variable with parameter θ . We want to mix an infinite number of Poisson distributions, each with a different value of θ . We let the weighting function be a pdf of θ , namely, a gamma with parameters α and β . For $x = 0, 1, 2, \dots$, the pmf of the compound distribution is

$$\begin{aligned} p(x) &= \int_0^\infty \left[\frac{1}{\beta^\alpha \Gamma(\alpha)} \theta^{\alpha-1} e^{-\theta/\beta} \right] \left[\frac{\theta^x e^{-\theta}}{x!} \right] d\theta \\ &= \frac{1}{\Gamma(\alpha) \beta^\alpha x!} \int_0^\infty \theta^{\alpha+x-1} e^{-\theta(1+\beta)/\beta} d\theta \\ &= \frac{\Gamma(\alpha+x) \beta^x}{\Gamma(\alpha) x! (1+\beta)^{\alpha+x}}, \end{aligned}$$

where the third line follows from the change of variable $t = \theta(1+\beta)/\beta$ to solve the integral of the second line.

An interesting case of this compound occurs when $\alpha = r$, a positive integer, and $\beta = (1-p)/p$, where $0 < p < 1$. In this case the pmf becomes

$$p(x) = \frac{(r+x-1)!}{(r-1)!} \frac{p^r (1-p)^x}{x!}, \quad x = 0, 1, 2, \dots$$

That is, this compound distribution is the same as that of the number of excess trials needed to obtain r successes in a sequence of independent trials, each with probability p of success; this is one form of the **negative binomial distribution**. The negative binomial distribution has been used successfully as a model for the number of accidents (see Weber, 1971). ■

In compounding, we can think of the original distribution of X as being a conditional distribution given θ , whose pdf is denoted by $f(x|\theta)$. Then the weighting function is treated as a pdf for θ , say $g(\theta)$. Accordingly, the joint pdf is $f(x|\theta)g(\theta)$, and the compound pdf can be thought of as the marginal (unconditional) pdf of X ,

$$h(x) = \int_{\theta} g(\theta) f(x|\theta) d\theta,$$

where a summation replaces integration in case θ has a discrete distribution. For illustration, suppose we know that the mean of the normal distribution is zero but the variance σ^2 equals $1/\theta > 0$, where θ has been selected from some random model. For convenience, say this latter is a gamma distribution with parameters α and β . Thus, given that θ , X is conditionally $N(0, 1/\theta)$ so that the joint distribution of X and θ is

$$f(x|\theta)g(\theta) = \left[\frac{\sqrt{\theta}}{\sqrt{2\pi}} \exp\left(\frac{-\theta x^2}{2}\right) \right] \left[\frac{1}{\beta^\alpha \Gamma(\alpha)} \theta^{\alpha-1} \exp(-\theta/\beta) \right],$$

for $-\infty < x < \infty$, $0 < \theta < \infty$. Therefore, the marginal (unconditional) pdf $h(x)$ of X is found by integrating out θ ; that is,

$$h(x) = \int_0^\infty \frac{\theta^{\alpha+1/2-1}}{\beta^\alpha \sqrt{2\pi} \Gamma(\alpha)} \exp\left[-\theta\left(\frac{x^2}{2} + \frac{1}{\beta}\right)\right] d\theta.$$

By comparing this integrand with a gamma pdf with parameters $\alpha + \frac{1}{2}$ and $[(1/\beta) + (x^2/2)]^{-1}$, we see that the integral equals

$$h(x) = \frac{\Gamma(\alpha + \frac{1}{2})}{\beta^\alpha \sqrt{2\pi} \Gamma(\alpha)} \left(\frac{2\beta}{2 + \beta x^2} \right)^{\alpha+1/2}, \quad -\infty < x < \infty.$$

It is interesting to note that if $\alpha = r/2$ and $\beta = 2/r$, where r is a positive integer, then X has an unconditional distribution, which is Student's t , with r degrees of freedom. That is, we have developed a generalization of Student's distribution through this type of mixing or compounding. We note that the resulting distribution (a generalization of Student's t) has much thicker tails than those of the conditional normal with which we started.

The next two examples offer two additional illustrations of this type of compounding.

Example 3.7.3. Suppose that we have a binomial distribution, but we are not certain about the probability p of success on a given trial. Suppose p has been selected first by some random process that has a beta pdf with parameters α and β . Thus X , the number of successes on n independent trials, has a conditional binomial distribution so that the joint pdf of X and p is

$$p(x|p)g(p) = \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} p^{\alpha-1} (1-p)^{\beta-1},$$

for $x = 0, 1, \dots, n$, $0 < p < 1$. Therefore, the unconditional pmf of X is given by the integral

$$\begin{aligned} h(x) &= \int_0^1 \frac{n! \Gamma(\alpha+\beta)}{x!(n-x)! \Gamma(\alpha) \Gamma(\beta)} p^{x+\alpha-1} (1-p)^{n-x+\beta-1} dp \\ &= \frac{n! \Gamma(\alpha+\beta) \Gamma(x+\alpha) \Gamma(n-x+\beta)}{x!(n-x)! \Gamma(\alpha) \Gamma(\beta) \Gamma(n+\alpha+\beta)}, \quad x = 0, 1, 2, \dots, n. \end{aligned}$$

Now suppose α and β are positive integers; since $\Gamma(k) = (k-1)!$, this unconditional (marginal or compound) pdf can be written

$$h(x) = \frac{n! (\alpha+\beta-1)! (x+\alpha-1)! (n-x+\beta-1)!}{x! (n-x)! (\alpha-1)! (\beta-1)! (n+\alpha+\beta-1)!}, \quad x = 0, 1, 2, \dots, n.$$

Because the conditional mean $E(X|p) = np$, the unconditional mean is $n\alpha/(\alpha+\beta)$ since $E(p)$ equals the mean $\alpha/(\alpha+\beta)$ of the beta distribution. ■

Example 3.7.4. In this example, we develop by compounding a heavy-tailed skewed distribution. Assume X has a conditional gamma pdf with parameters k and θ^{-1} . The weighting function for θ is a gamma pdf with parameters α and β . Thus the unconditional (marginal or compounded) pdf of X is

$$\begin{aligned} h(x) &= \int_0^\infty \left[\frac{\theta^{\alpha-1} e^{-\theta/\beta}}{\beta^\alpha \Gamma(\alpha)} \right] \left[\frac{\theta^k x^{k-1} e^{-\theta x}}{\Gamma(k)} \right] d\theta \\ &= \int_0^\infty \frac{x^{k-1} \theta^{\alpha+k-1}}{\beta^\alpha \Gamma(\alpha) \Gamma(k)} e^{-\theta(1+\beta x)/\beta} d\theta. \end{aligned}$$

Comparing this integrand to the gamma pdf with parameters $\alpha+k$ and $\beta/(1+\beta x)$, we see that

$$h(x) = \frac{\Gamma(\alpha+k) \beta^k x^{k-1}}{\Gamma(\alpha) \Gamma(k) (1+\beta x)^{\alpha+k}}, \quad 0 < x < \infty,$$

which is the pdf of the **generalized Pareto distribution** (and a generalization of the F distribution). Of course, when $k = 1$ (so that X has a conditional exponential distribution), the pdf is

$$h(x) = \alpha \beta (1 + \beta x)^{-(\alpha+1)}, \quad 0 < x < \infty,$$

which is the **Pareto pdf**. Both of these compound pdfs have thicker tails than the original (conditional) gamma distribution.

While the cdf of the generalized Pareto distribution cannot be expressed in a simple closed form, that of the Pareto distribution is

$$H(x) = \int_0^x \alpha \beta (1 + \beta t)^{-(\alpha+1)} dt = 1 - (1 + \beta x)^{-\alpha}, \quad 0 \leq x < \infty.$$

From this, we can create another useful long-tailed distribution by letting $X = Y^\tau$, $0 < \tau$. Thus Y has the cdf

$$G(y) = P(Y \leq y) = P[X^{1/\tau} \leq y] = P[X \leq y^\tau].$$

Hence, this probability is equal to

$$G(y) = H(y^\tau) = 1 - (1 + \beta y^\tau)^{-\alpha}, \quad 0 < y < \infty,$$

with corresponding pdf

$$G'(y) = g(y) = \frac{\alpha \beta \tau y^{\tau-1}}{(1 + \beta y^\tau)^{\alpha+1}}, \quad 0 < y < \infty.$$

We call the associated distribution the **transformed Pareto distribution** or the **Burr distribution** (Burr, 1942), and it has proved to be a useful one in modeling thicker-tailed distributions. ■

EXERCISES

3.7.1. Suppose Y has a $\Gamma(\alpha, \beta)$ distribution. Let $X = e^Y$. Show that the pdf of X is given by expression (3.7.5). Determine the cdf of X in terms of the cdf of a Γ -distribution. Derive the mean and variance of X .

3.7.2. Write R functions for the pdf and cdf of the random variable in Exercise 3.7.1.

3.7.3. In Example 3.7.1, derive the pdf of the mixture distribution given in expression (3.7.6), then obtain its mean and variance as given in expressions (3.7.7) and (3.7.8).

3.7.4. Using the R function for the pdf in Exercise 3.7.2 and `dgamma`, write an R function for the mixture pdf (3.7.6). For $\alpha = \beta = 2$, obtain a page of plots of this density for $p = 0.05, 0.10, 0.15$ and 0.20 .

3.7.5. Consider the mixture distribution $(9/10)N(0, 1) + (1/10)N(0, 9)$. Show that its kurtosis is 8.34.

3.7.6. Let X have the conditional geometric pmf $\theta(1 - \theta)^{x-1}$, $x = 1, 2, \dots$, where θ is a value of a random variable having a beta pdf with parameters α and β . Show that the marginal (unconditional) pmf of X is

$$\frac{\Gamma(\alpha + \beta)\Gamma(\alpha + 1)\Gamma(\beta + x - 1)}{\Gamma(\alpha)\Gamma(\beta)\Gamma(\alpha + \beta + x)}, \quad x = 1, 2, \dots$$

If $\alpha = 1$, we obtain

$$\frac{\beta}{(\beta + x)(\beta + x - 1)}, \quad x = 1, 2, \dots,$$

which is one form of **Zipf's law**.

3.7.7. Repeat Exercise 3.7.6, letting X have a conditional negative binomial distribution instead of the geometric one.

3.7.8. Let X have a generalized Pareto distribution with parameters k , α , and β . Show, by change of variables, that $Y = \beta X / (1 + \beta X)$ has a beta distribution.

3.7.9. Show that the failure rate (hazard function) of the Pareto distribution is

$$\frac{h(x)}{1 - H(x)} = \frac{\alpha}{\beta^{-1} + x}.$$

Find the failure rate (hazard function) of the Burr distribution with cdf

$$G(y) = 1 - \left(\frac{1}{1 + \beta y^\tau} \right)^\alpha, \quad 0 \leq y < \infty.$$

In each of these two failure rates, note what happens as the value of the variable increases.

3.7.10. For the Burr distribution, show that

$$E(X^k) = \frac{1}{\beta^{k/\tau}} \Gamma\left(\alpha - \frac{k}{\tau}\right) \Gamma\left(\frac{k}{\tau} + 1\right) / \Gamma(\alpha),$$

provided $k < \alpha\tau$.

3.7.11. Let the number X of accidents have a Poisson distribution with mean $\lambda\theta$. Suppose λ , the liability to have an accident, has, given θ , a gamma pdf with parameters $\alpha = h$ and $\beta = h^{-1}$; and θ , an accident proneness factor, has a generalized Pareto pdf with parameters α , $\lambda = h$, and k . Show that the unconditional pdf of X is

$$\frac{\Gamma(\alpha+k)\Gamma(\alpha+h)\Gamma(\alpha+h+k)\Gamma(h+k)\Gamma(k+x)}{\Gamma(\alpha)\Gamma(\alpha+k+h)\Gamma(h)\Gamma(k)\Gamma(\alpha+h+k+x)x!}, \quad x = 0, 1, 2, \dots,$$

sometimes called the **generalized Waring pmf**.

3.7.12. Let X have a conditional Burr distribution with fixed parameters β and τ , given parameter α .

- (a) If α has the geometric pmf $p(1-p)^\alpha$, $\alpha = 0, 1, 2, \dots$, show that the unconditional distribution of X is a Burr distribution.
- (b) If α has the exponential pdf $\beta^{-1}e^{-\alpha/\beta}$, $\alpha > 0$, find the unconditional pdf of X .

3.7.13. Let X have the conditional Weibull pdf

$$f(x|\theta) = \theta\tau x^{\tau-1}e^{-\theta x^\tau}, \quad 0 < x < \infty,$$

and let the pdf (weighting function) $g(\theta)$ be gamma with parameters α and β . Show that the compound (marginal) pdf of X is that of Burr.

3.7.14. If X has a Pareto distribution with parameters α and β and if c is a positive constant, show that $Y = cX$ has a Pareto distribution with parameters α and β/c .

Chapter 4

Some Elementary Statistical Inferences

4.1 Sampling and Statistics

In Chapter 2, we introduced the concepts of samples and statistics. We continue with this development in this chapter while introducing the main tools of inference: confidence intervals and tests of hypotheses.

In a typical statistical problem, we have a random variable X of interest, but its pdf $f(x)$ or pmf $p(x)$ is not known. Our ignorance about $f(x)$ or $p(x)$ can roughly be classified in one of two ways:

1. $f(x)$ or $p(x)$ is completely unknown.
2. The form of $f(x)$ or $p(x)$ is known down to a parameter θ , where θ may be a vector.

For now, we consider the second classification, although some of our discussion pertains to the first classification also. Some examples are the following:

- (a) X has an exponential distribution, $\text{Exp}(\theta)$, (3.3.6), where θ is unknown.
- (b) X has a binomial distribution $b(n, p)$, (3.1.2), where n is known but p is unknown.
- (c) X has a gamma distribution $\Gamma(\alpha, \beta)$, (3.3.2), where both α and β are unknown.
- (d) X has a normal distribution $N(\mu, \sigma^2)$, (3.4.6), where both the mean μ and the variance σ^2 of X are unknown.

We often denote this problem by saying that the random variable X has a density or mass function of the form $f(x; \theta)$ or $p(x; \theta)$, where $\theta \in \Omega$ for a specified set Ω . For example, in (a) above, $\Omega = \{\theta | \theta > 0\}$. We call θ a parameter of the distribution. Because θ is unknown, we want to estimate it.

In this process, our information about the unknown distribution of X or the unknown parameters of the distribution of X comes from a sample on X . The sample observations have the same distribution as X , and we denote them as the random variables X_1, X_2, \dots, X_n , where n denotes the **sample size**. When the sample is actually drawn, we use lower case letters x_1, x_2, \dots, x_n as the values or **realizations** of the sample. Often we assume that the sample observations X_1, X_2, \dots, X_n are also mutually independent, in which case we call the sample a random sample, which we now formally define:

Definition 4.1.1. *If the random variables X_1, X_2, \dots, X_n are independent and identically distributed (iid), then these random variables constitute a **random sample** of size n from the common distribution.*

Often, functions of the sample are used to summarize the information in a sample. These are called statistics, which we define as:

Definition 4.1.2. *Let X_1, X_2, \dots, X_n denote a sample on a random variable X . Let $T = T(X_1, X_2, \dots, X_n)$ be a function of the sample. Then T is called a **statistic**.*

Once the sample is drawn, then t is called the realization of T , where $t = T(x_1, x_2, \dots, x_n)$ and x_1, x_2, \dots, x_n is the realization of the sample.

4.1.1 Point Estimators

Using the above terminology, the problem we discuss in this chapter is phrased as: Let X_1, X_2, \dots, X_n denote a random sample on a random variable X with a density or mass function of the form $f(x; \theta)$ or $p(x; \theta)$, where $\theta \in \Omega$ for a specified set Ω . In this situation, it makes sense to consider a statistic T , which is an **estimator** of θ . More formally, T is called a **point estimator** of θ . While we call T an estimator of θ , we call its realization t an **estimate** of θ .

There are several properties of point estimators that we discuss in this book. We begin with a simple one, unbiasedness.

Definition 4.1.3 (Unbiasedness). *Let X_1, X_2, \dots, X_n denote a sample on a random variable X with pdf $f(x; \theta)$, $\theta \in \Omega$. Let $T = T(X_1, X_2, \dots, X_n)$ be a statistic. We say that T is an **unbiased estimator** of θ if $E(T) = \theta$.*

In Chapters 6 and 7, we discuss several theories of estimation in general. The purpose of this chapter, though, is an introduction to inference, so we briefly discuss the **maximum likelihood estimator** (**mle**) and then use it to obtain point estimators for some of the examples cited above. We expand on this theory in Chapter 6. Our discussion is for the continuous case. For the discrete case, simply replace the pdf with the pmf.

In our problem, the information in the sample and the parameter θ are involved in the joint distribution of the random sample; i.e., $\prod_{i=1}^n f(x_i; \theta)$. We want to view this as a function of θ , so we write it as

$$L(\theta) = L(\theta; x_1, x_2, \dots, x_n) = \prod_{i=1}^n f(x_i; \theta). \quad (4.1.1)$$

This is called the **likelihood function** of the random sample. As an estimate of θ , a measure of the center of $L(\theta)$ seems appropriate. An often-used estimate is the value of θ that provides a maximum of $L(\theta)$. If it is unique, this is called the **maximum likelihood estimator** (mle), and we denote it as $\hat{\theta}$; i.e.,

$$\hat{\theta} = \text{Argmax } L(\theta). \quad (4.1.2)$$

In practice, it is often much easier to work with the log of the likelihood, that is, the function $l(\theta) = \log L(\theta)$. Because the log is a strictly increasing function, the value that maximizes $l(\theta)$ is the same as the value that maximizes $L(\theta)$. Furthermore, for most of the models discussed in this book, the pdf (or pmf) is a differentiable function of θ , and frequently $\hat{\theta}$ solves the equation

$$\frac{\partial l(\theta)}{\partial \theta} = 0. \quad (4.1.3)$$

If θ is a vector of parameters, this results in a system of equations to be solved simultaneously; see Example 4.1.3. These equations are often referred to as the **mle estimating equations**, (EE).

As we show in Chapter 6, under general conditions, mles have some good properties. One property that we need at the moment concerns the situation where, besides the parameter θ , we are also interested in the parameter $\eta = g(\theta)$ for a specified function g . Then, as Theorem 6.1.2 of Chapter 6 shows, the mle of η is $\hat{\eta} = g(\hat{\theta})$, where $\hat{\theta}$ is the mle of θ . We now proceed with some examples, including data realizations.

Example 4.1.1 (Exponential Distribution). Suppose the common pdf of the random sample X_1, X_2, \dots, X_n is the $\Gamma(1, \theta)$ density $f(x) = \theta^{-1} \exp\{-x/\theta\}$ with support $0 < x < \infty$; see expression (3.3.2). This gamma distribution is often called the exponential distribution. The log of the likelihood function is given by

$$l(\theta) = \log \prod_{i=1}^n \frac{1}{\theta} e^{-x_i/\theta} = -n \log \theta - \theta^{-1} \sum_{i=1}^n x_i.$$

The first partial of the log-likelihood with respect to θ is

$$\frac{\partial l(\theta)}{\partial \theta} = -n\theta^{-1} + \theta^{-2} \sum_{i=1}^n x_i.$$

Setting this partial to 0 and solving for θ , we obtain the solution \bar{x} . There is only one critical value and, furthermore, the second partial of the log-likelihood evaluated at \bar{x} is strictly negative, verifying that it provides a maximum. Hence, for this example, the statistic $\hat{\theta} = \bar{X}$ is the mle of θ . Because $E(X) = \theta$, we have that $E(\bar{X}) = \theta$ and, hence, $\hat{\theta}$ is an unbiased estimator of θ .

Rasmussen (1992), page 92, presents a data set where the variable of interest X is the number of operating hours until the first failure of air-conditioning units for Boeing 720 airplanes. A random sample of size $n = 13$ was obtained and its

realized values are:

359 413 25 130 90 50 50 487 102 194 55 74 97

For instance, 359 hours is the realization of the random variable X_1 . The data range from 25 to 487 hours. Assuming an exponential model, the point estimate of θ discussed above is the arithmetic average of this data. Assuming that the data set is stored in the R vector `ophrs`, this average is computed in R by

`mean(ophrs);` 163.5385

Hence our point estimate of θ , the mean of X , is 163.54 hours. How close is 163.54 hours to the true θ ? We provide an answer to this question in the next section. ■

Example 4.1.2 (Binomial Distribution). Let X be one or zero if, respectively, the outcome of a Bernoulli experiment is success or failure. Let θ , $0 < \theta < 1$, denote the probability of success. Then by (3.1.1), the pmf of X is

$$p(x; \theta) = \theta^x (1 - \theta)^{1-x}, \quad x = 0 \text{ or } 1.$$

If X_1, X_2, \dots, X_n is a random sample on X , then the likelihood function is

$$L(\theta) = \prod_{i=1}^n p(x_i; \theta) = \theta^{\sum_{i=1}^n x_i} (1 - \theta)^{n - \sum_{i=1}^n x_i}, \quad x_i = 0 \text{ or } 1.$$

Taking logs, we have

$$l(\theta) = \sum_{i=1}^n x_i \log \theta + \left(n - \sum_{i=1}^n x_i \right) \log(1 - \theta), \quad x_i = 0 \text{ or } 1.$$

The partial derivative of $l(\theta)$ is

$$\frac{\partial l(\theta)}{\partial \theta} = \frac{\sum_{i=1}^n x_i}{\theta} - \frac{n - \sum_{i=1}^n x_i}{1 - \theta}.$$

Setting this to 0 and solving for θ , we obtain $\hat{\theta} = n^{-1} \sum_{i=1}^n X_i = \bar{X}$; i.e., the mle is the proportion of successes in the n trials. Because $E(X) = \theta$, $\hat{\theta}$ is an unbiased estimator of θ .

Devore (2012) discusses a study involving ceramic hip replacements which for some patients can be squeaky; see, also, page 30 of Kloke and McKean (2014). In this study, 28 out of 143 hip replacements squeaked. In terms of the above discussion, we have a realization of a sample of size $n = 143$ from a binomial distribution where success is a hip replacement that squeaks and failure is one that does not squeak. Let θ denote the probability of success. Then our estimate of θ based on this sample is $\hat{\theta} = 28/143 = 0.1958$. This is straightforward to calculate but, for later use, the R code `prop.test(28, 143)` calculates this proportion. ■

Example 4.1.3 (Normal Distribution). Let X have a $N(\mu, \sigma^2)$ distribution with the pdf given in expression (3.4.6). In this case, $\boldsymbol{\theta}$ is the vector $\boldsymbol{\theta} = (\mu, \sigma)$. If X_1, X_2, \dots, X_n is a random sample on X , then the log of the likelihood function simplifies to

$$l(\mu, \sigma) = -\frac{n}{2} \log 2\pi - n \log \sigma - \frac{1}{2} \sum_{i=1}^n \left(\frac{x_i - \mu}{\sigma} \right)^2. \quad (4.1.4)$$

The two partial derivatives simplify to

$$\frac{\partial l(\mu, \sigma)}{\partial \mu} = -\sum_{i=1}^n \left(\frac{x_i - \mu}{\sigma} \right) \left(-\frac{1}{\sigma} \right) \quad (4.1.5)$$

$$\frac{\partial l(\mu, \sigma)}{\partial \sigma} = -\frac{n}{\sigma} + \frac{1}{\sigma^3} \sum_{i=1}^n (x_i - \mu)^2. \quad (4.1.6)$$

Setting these to 0 and solving simultaneously, we see that the mles are

$$\hat{\mu} = \bar{X} \quad (4.1.7)$$

$$\hat{\sigma}^2 = n^{-1} \sum_{i=1}^n (X_i - \bar{X})^2. \quad (4.1.8)$$

Notice that we have used the property that the mle of $\hat{\sigma}^2$ is the mle of σ^2 . As we have shown in Chapter 2, (2.8.6), the estimator \bar{X} is an unbiased estimator for μ . Further, from Example 2.8.7 of Section 2.8 we know that the following statistic

$$S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 \quad (4.1.9)$$

is an unbiased estimator of σ^2 . Thus for the mle of σ^2 , $E(\hat{\sigma}^2) = [n/(n-1)]\sigma^2$. Hence, the mle is a biased estimator of σ^2 . Note, though, that the bias of $\hat{\sigma}^2$ is $E(\hat{\sigma}^2 - \sigma^2) = -\sigma^2/n$, which converges to 0 as $n \rightarrow \infty$. In practice, however, S^2 is the preferred estimator of σ^2 .

Rasmussen (1991), page 65, discusses a study to measure the concentration of sulfur dioxide in a damaged Bavarian forest. The following data set is the realization of a random sample of size $n = 24$ measurements (micro grams per cubic meter) of this sulfur dioxide concentration:

```
33.4 38.6 41.7 43.9 44.4 45.3 46.1 47.6 50.0 52.4 52.7 53.9  
54.3 55.1 56.4 56.5 60.7 61.8 62.2 63.4 65.5 66.6 70.0 71.5.
```

These data are also in the R data file `sulfurdio.rda` at the site listed in the Preface. Assuming these data are in the R vector `sulfurdioxide`, the following R segment obtains the estimates of the true mean and variance (both s^2 and $\hat{\sigma}^2$ are computed):

```
mean(sulfurdioxide); var(sulfurdioxide); (23/24)*var(sulfurdioxide)  
53.91667 101.4797 97.25139.
```

Hence, we estimate the true mean concentration of sulfur dioxide in this damaged Bavarian forest to be 53.92 micro grams per cubic meter. The realization of the statistic S^2 is $s^2 = 101.48$, while the biased estimate of σ^2 is 97.25. Rasmussen notes that the average concentration of sulfur dioxide in undamaged areas of Bavaria is 20 micro grams per cubic meter. This value appears to be quite distant from the sample values. This will be discussed statistically in later sections. ■

In all three of these examples, standard differential calculus methods led us to the solution. For the next example, the support of the random variable involves θ and, hence, it is not surprising that for this case differential calculus is not useful.

Example 4.1.4 (Uniform Distribution). Let X_1, \dots, X_n be iid with the uniform $(0, \theta)$ density; i.e., $f(x) = 1/\theta$ for $0 < x < \theta$, 0 elsewhere. Because θ is in the support, differentiation is not helpful here. The likelihood function can be written as

$$L(\theta) = \theta^{-n} I(\max\{x_i\}, \theta),$$

where $I(a, b)$ is 1 or 0 if $a \leq b$ or $a > b$, respectively. The function $L(\theta)$ is a decreasing function of θ for all $\theta \geq \max\{x_i\}$ and is 0 otherwise [sketch the graph of $L(\theta)$]. So the maximum occurs at the smallest value that θ can assume; i.e., the mle is $\hat{\theta} = \max\{X_i\}$. ■

4.1.2 Histogram Estimates of pmfs and pdfs

Let X_1, \dots, X_n be a random sample on a random variable X with cdf $F(x)$. In this section, we briefly discuss a histogram of the sample, which is an estimate of the pmf, $p(x)$, or the pdf, $f(x)$, of X depending on whether X is discrete or continuous. Other than X being a discrete or continuous random variable, we make no assumptions on the form of the distribution of X . In particular, we do not assume a parametric form of the distribution as we did for the above discussion on maximum likelihood estimates; hence, the histogram that we present is often called a **nonparametric** estimator. See Chapter 10 for a general discussion of nonparametric inference. We discuss the discrete situation first.

The Distribution of X Is Discrete

Assume that X is a discrete random variable with pmf $p(x)$. Let X_1, \dots, X_n be a random sample on X . First, suppose that the space of X is finite, say, $\mathcal{D} = \{a_1, \dots, a_m\}$. An intuitive estimate of $p(a_j)$ is the relative frequency of a_j in the sample. We express this more formally as follows. For $j = 1, 2, \dots, m$, define the statistics

$$I_j(X_i) = \begin{cases} 1 & X_i = a_j \\ 0 & X_i \neq a_j. \end{cases}$$

Then our intuitive estimate of $p(a_j)$ can be expressed by the sample average

$$\hat{p}(a_j) = \frac{1}{n} \sum_{i=1}^n I_j(X_i). \quad (4.1.10)$$

These estimators $\{\hat{p}(a_1), \dots, \hat{p}(a_m)\}$ constitute the nonparametric estimate of the pmf $p(x)$. Note that $I_j(X_i)$ has a Bernoulli distribution with probability of success $p(a_j)$. Because

$$E[\hat{p}(a_j)] = \frac{1}{n} \sum_{i=1}^n E[I_j(X_i)] = \frac{1}{n} \sum_{i=1}^n p(a_j) = p(a_j), \quad (4.1.11)$$

$\hat{p}(a_j)$ is an unbiased estimator of $p(a_j)$.

Next, suppose that the space of X is infinite, say, $\mathcal{D} = \{a_1, a_2, \dots\}$. In practice, we select a value, say, a_m , and make the groupings

$$\{a_1\}, \{a_2\}, \dots, \{a_m\}, \tilde{a}_{m+1} = \{a_{m+1}, a_{m+2}, \dots\}. \quad (4.1.12)$$

Let $\hat{p}(\tilde{a}_{m+1})$ be the proportion of sample items that are greater than or equal to a_{m+1} . Then the estimates $\{\hat{p}(a_1), \dots, \hat{p}(a_m), \hat{p}(\tilde{a}_{m+1})\}$ form our estimate of $p(x)$. For the merging of groups, a rule of thumb is to select m so that the frequency of the category a_m exceeds twice the combined frequencies of the categories a_{m+1}, a_{m+2}, \dots .

A histogram is a **barplot** of $\hat{p}(a_j)$ versus a_j . There are two cases to consider. For the first case, suppose the values a_j represent qualitative categories, for example, hair colors of a population of people. In this case, there is no ordinal information in the a_j s. The usual histogram for such data consists of nonabutting bars with heights $\hat{p}(a_j)$ that are plotted in decreasing order of the $\hat{p}(a_1)$ s. Such histograms are usually called **bar charts**. An example is helpful here.

Example 4.1.5 (Hair Color of Scottish School Children). Kendall and Sturat (1979) present data on the eye and hair color of Scottish schoolchildren in the early 1900s. The data are also in the file `scotteyehair.rda` at the site listed in the Preface. In this example, we consider hair color. The discrete random variable is the hair color of a Scottish child with categories fair, red, medium, dark, and black. The results that Kendall and Sturat present are based on a sample of $n = 22,361$ Scottish school children. The frequency distribution of this sample and the estimate of the pmf are

	Fair	Red	Medium	Dark	Black
Count	5789	1319	9418	5678	157
$\hat{p}(a_j)$	0.259	0.059	0.421	0.254	0.007

The bar chart of this sample is shown in Figure 4.1.1. Assume that the counts (second row of the table) are in the R vector `vec`. Then the following R segment computes this bar chart:

```
n=sum(vec); vecs = sort(vec,decreasing=T)/n
nms = c("Medium","Fair","Dark","Red","Black")
barplot(vecs,beside=TRUE,names.arg=nms,ylab="",xlab="Haircolor")
```

For the second case, assume that the values in the space \mathcal{D} are **ordinal** in nature; i.e., the natural ordering of the a_j s is numerically meaningful. In this case, the usual histogram is an abutting bar chart with heights $\hat{p}(a_j)$ that are plotted in the natural order of the a_j s, as in the following example.

Example 4.1.6 (Simulated Poisson Variates). The following 30 data points are simulated values drawn from a Poisson distribution with mean $\lambda = 2$; see Example 4.8.2 for the generation of Poisson variates.

2	1	1	1	1	5	1	1	3	0	2	1	1	3	4
2	1	2	2	6	5	2	3	2	4	1	3	1	3	0

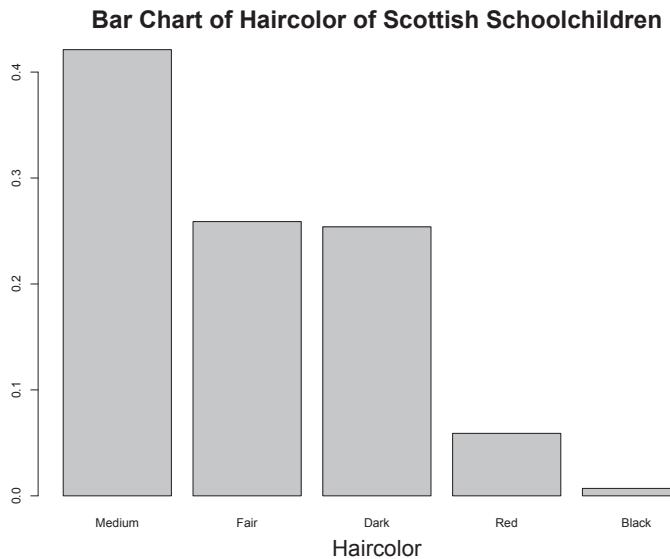

Figure 4.1.1: Bar chart of the Scottish hair color data discussed in Example 4.1.5.

The nonparametric estimate of the pmf is

j	0	1	2	3	4	5	≥ 6
$\hat{p}(j)$	0.067	0.367	0.233	0.167	0.067	0.067	0.033

The histogram for this data set is given in Figure 4.1.2. Note that counts are used for the vertical axis. If the R vector x contains the 30 data points, then the following R code computes this histogram:

```
brs=seq(-.5,6.5,1);hist(x,breaks=brs,xlab="Number of events",ylab="")
```

■

The Distribution of X Is Continuous

For this section, assume that the random sample X_1, \dots, X_n is from a continuous random variable X with continuous pdf $f(t)$. We first sketch an estimate for this pdf at a specified value of x . Then we use this estimate to develop a histogram estimate of the pdf. For an arbitrary but fixed point x and a given $h > 0$, consider the interval $(x - h, x + h)$. By the mean value theorem for integrals, we have for some ξ , $|x - \xi| < h$, that

$$P(x - h < X < x + h) = \int_{x-h}^{x+h} f(t) dt = f(\xi)2h \approx f(x)2h.$$

The nonparametric estimate of the leftside is the proportion of the sample items that fall in the interval $(x - h, x + h)$. This suggests the following nonparametric

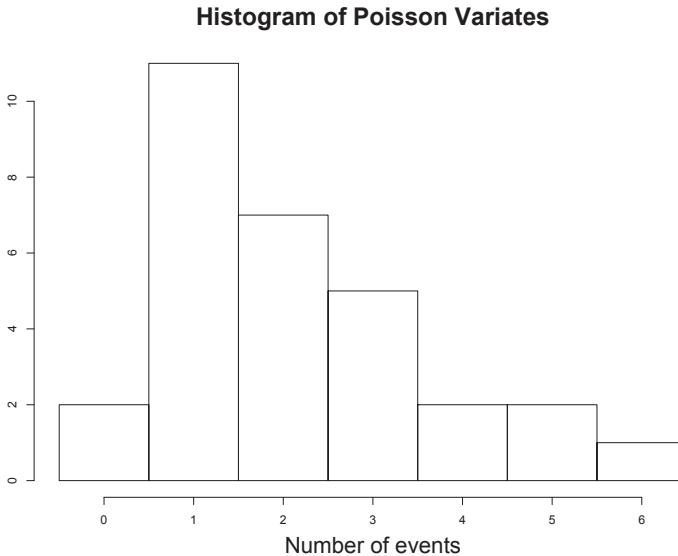

Figure 4.1.2: Histogram of the Poisson variates of Example 4.1.6.

estimate of $f(x)$ at a given x :

$$\hat{f}(x) = \frac{\#\{x - h < X_i < x + h\}}{2hn}. \quad (4.1.13)$$

To write this more formally, consider the indicator statistic

$$I_i(x) = \begin{cases} 1 & x - h < X_i < x + h \\ 0 & \text{otherwise,} \end{cases} \quad i = 1, \dots, n.$$

Then a nonparametric estimator of $f(x)$ is

$$\hat{f}(x) = \frac{1}{2hn} \sum_{i=1}^n I_i(x). \quad (4.1.14)$$

Since the sample items are identically distributed,

$$E[\hat{f}(x)] = \frac{1}{2hn} n f(\xi) 2h = f(\xi) \rightarrow f(x),$$

as $h \rightarrow 0$. Hence $\hat{f}(x)$ is approximately an unbiased estimator of the density $f(x)$. In density estimation terminology, the indicator function I_i is called a **rectangular kernel** with **bandwidth** $2h$. See Sheather and Jones (1991) and Chapter 6 of Lehmann (1999) for discussions of density estimation. The R function `density` provides a density estimator with several options. For the examples in the text, we use the default option as in Example 4.1.7.

The histogram provides a somewhat crude but often used estimator of the pdf, so a few remarks on it are pertinent. Let x_1, \dots, x_n be the realized values of the random sample on a continuous random variable X with pdf $f(x)$. Our histogram estimate of $f(x)$ is obtained as follows. While for the discrete case, there are natural classes for the histogram, for the continuous case these classes must be chosen. One way of doing this is to select a positive integer m , an $h > 0$, and a value a such that $a < \min x_i$, so that the m intervals

$$(a-h, a+h], (a+h, a+3h], (a+3h, a+5h], \dots, (a+(2m-3)h, a+(2m-1)h] \quad (4.1.15)$$

cover the range of the sample $[\min x_i, \max x_i]$. These intervals form our classes. Let $A_j = (a + (2j - 3)h, a + (2j - 1)h]$ for $j = 1, \dots, m$.

Let $\hat{f}_h(x)$ denote our histogram estimate. If $x \leq a - h$ or $x > a + (2m - 1)h$ then define $\hat{f}_h(x) = 0$. For $a - h < x \leq a + (2m - 1)h$, x is in one, and only one, A_j . For $x \in A_j$, define $\hat{f}_h(x)$ to be:

$$\hat{f}_h(x) = \frac{\#\{x_i \in A_j\}}{2hn}. \quad (4.1.16)$$

Note that $\hat{f}_h(x) \geq 0$ and that

$$\begin{aligned} \int_{-\infty}^{\infty} \hat{f}_h(x) dx &= \int_{a-h}^{a+(2m-1)h} \hat{f}_h(x) dx = \sum_{j=1}^m \int_{A_j} \frac{\#\{x_i \in A_j\}}{2hn} dx \\ &= \frac{1}{2hn} \sum_{j=1}^m \#\{x_i \in A_j\} [h(2j - 1 - 2j + 3)] = \frac{2h}{2hn} n = 1; \end{aligned}$$

so, $\hat{f}_h(x)$ satisfies the properties of a pdf.

For the discrete case, except when classes are merged, the histogram is unique. For the continuous case, though, the histogram depends on the classes chosen. The resulting picture can be quite different if the classes are changed. Unless there is a compelling reason for the class selection, we recommend using the default classes selected by the computational algorithm. The histogram algorithms in most statistical packages such as R are current on recent research for selection of classes. The histogram in the following example is based on default classes.

Example 4.1.7. In Example 4.1.3, we presented a data set involving sulfur dioxide concentrations in a damaged Bavarian forest. The histogram of this data set is found in Figure 4.1.3. There are only 24 data points in the sample which are far too few for density estimation. With this in mind, although the distribution of data is mound shaped, the center appears to be too flat for normality. We have overlaid the histogram with the default R density estimate (solid line) which confirms some caution on normality. Recall that sample mean and standard deviations for this data are 53.91667 and 10.07371, respectively. So we also plotted the normal pdf with this mean and standard deviation (dashed line). The R code assumes that the data are in the R vector `sulfurdioxide`.

```
hist(sulfurdioxide, xlab="Sulfurdioxide", ylab=" ", pr=T, ylim=c(0, .04))
```

```
lines(density(sulfurdioxide))
y=dnorm(sulfurdioxide,53.91667,10.07371);lines(y~sulfurdioxide,lty=2)
The normal density plot seems to be a poor fit. ■
```

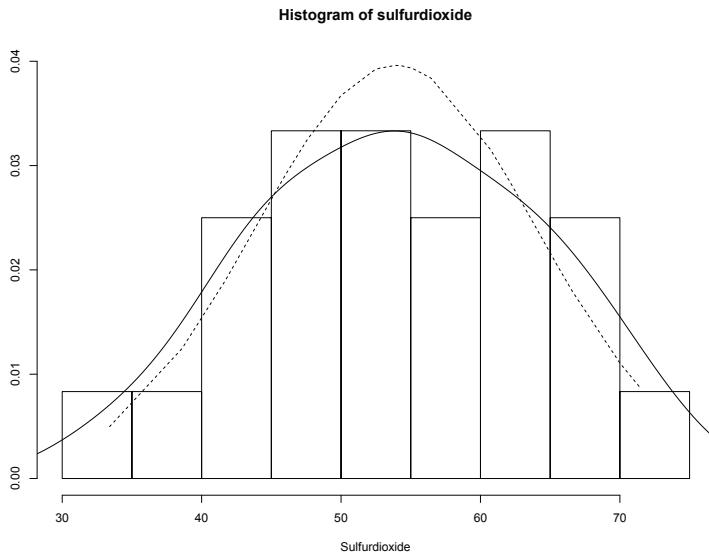

Figure 4.1.3: Histogram of the sulfur dioxide concentrations in a damaged Bavarian forest overlaid with a density estimate (solid line) and a normal pdf (dashed line) with mean and variance replaced by the sample mean and standard deviations, respectively. Data are given in Example 4.1.3.

EXERCISES

4.1.1. Twenty motors were put on test under a high-temperature setting. The lifetimes in hours of the motors under these conditions are given below. Also, the data are in the file `lifetimemotor.rda` at the site listed in the Preface. Suppose we assume that the lifetime of a motor under these conditions, X , has a $\Gamma(1, \theta)$ distribution.

1	4	5	21	22	28	40	42	51	53
58	67	95	124	124	160	202	260	303	363

- (a) Obtain a histogram of the data and overlay it with a density estimate, using the code `hist(x,pr=T); lines(density(x))` where the R vector x contains the data. Based on this plot, do you think that the $\Gamma(1, \theta)$ model is credible?
- (b) Assuming a $\Gamma(1, \theta)$ model, obtain the maximum likelihood estimate $\hat{\theta}$ of θ and locate it on your histogram. Next overlay the pdf of a $\Gamma(1, \hat{\theta})$ distribution on

the histogram. Use the R function `dgamma(x, shape=1, scale=θ̂)` to evaluate the pdf.

- (c) Obtain the sample median of the data, which is an estimate of the median lifetime of a motor. What parameter is it estimating (i.e., determine the median of X)?
- (d) Based on the mle, what is another estimate of the median of X ?

4.1.2. Here are the weights of 26 professional baseball pitchers; [see page 76 of Hettmansperger and McKean (2011) for the complete data set]. The data are in R file `bb.rda`. Suppose we assume that the weight of a professional baseball pitcher is normally distributed with mean μ and variance σ^2 .

160	175	180	185	185	185	190	190	195	195	195	200	200
200	200	205	205	210	210	218	219	220	222	225	225	232

- (a) Obtain a histogram of the data. Based on this plot, is a normal probability model credible?
- (b) Obtain the maximum likelihood estimates of μ , σ^2 , σ , and μ/σ . Locate your estimate of μ on your plot in part (a). Then overlay the normal pdf with these estimates on your histogram in Part (a).
- (c) Using the binomial model, obtain the maximum likelihood estimate of the proportion p of professional baseball pitchers who weigh over 215 pounds.
- (d) Determine the mle of p assuming that the weight of a professional baseball player follows the normal probability model $N(\mu, \sigma^2)$ with μ and σ unknown.

4.1.3. Suppose the number of customers X that enter a store between the hours 9:00 a.m. and 10:00 a.m. follows a Poisson distribution with parameter θ . Suppose a random sample of the number of customers that enter the store between 9:00 a.m. and 10:00 a.m. for 10 days results in the values

9	7	9	15	10	13	11	7	2	12
---	---	---	----	----	----	----	---	---	----

- (a) Determine the maximum likelihood estimate of θ . Show that it is an unbiased estimator.
- (b) Based on these data, obtain the realization of your estimator in part (a). Explain the meaning of this estimate in terms of the number of customers.

4.1.4. For Example 4.1.3, verify equations (4.1.4)–(4.1.8).

4.1.5. Let X_1, X_2, \dots, X_n be a random sample from a continuous-type distribution.

- (a) Find $P(X_1 \leq X_2), P(X_1 \leq X_2, X_1 \leq X_3), \dots, P(X_1 \leq X_i, i = 2, 3, \dots, n)$.

- (b) Suppose the sampling continues until X_1 is no longer the smallest observation (i.e., $X_j < X_1 \leq X_i, i = 2, 3, \dots, j-1$). Let Y equal the number of trials, not including X_1 , until X_1 is no longer the smallest observation (i.e., $Y = j - 1$). Show that the distribution of Y is

$$P(Y = y) = \frac{1}{y(y+1)}, \quad y = 1, 2, 3, \dots$$

- (c) Compute the mean and variance of Y if they exist.

4.1.6. Consider the estimator of the pmf in expression (4.1.10). In equation (4.1.11), we showed that this estimator is unbiased. Find the variance of the estimator and its mgf.

4.1.7. The data set on Scottish schoolchildren discussed in Example 4.1.5 included the eye colors of the children also. The frequencies of their eye colors are

Blue	Light	Medium	Dark
2978	6697	7511	5175

Use these frequencies to obtain a bar chart and an estimate of the associated pmf.

4.1.8. Recall that for the parameter $\eta = g(\theta)$, the mle of η is $g(\hat{\theta})$, where $\hat{\theta}$ is the mle of θ . Assuming that the data in Example 4.1.6 were drawn from a Poisson distribution with mean λ , obtain the mle of λ and then use it to obtain the mle of the pmf. Compare the mle of the pmf to the nonparametric estimate. Note: For the domain value 6, obtain the mle of $P(X \geq 6)$.

4.1.9. Consider the nonparametric estimator, (4.1.14), of a pdf.

- (a) Obtain its mean and determine the bias of the estimator.
 (b) Obtain the variance of the estimator.

4.1.10. This data set was downloaded from the site <http://lib.stat.cmu.edu/DASL/> at Carnegie-Melon university. The original source is Willerman et al. (1991). The data consist of a sample of brain information recorded on 40 college students. The variables include gender, height, weight, three IQ measurements, and Magnetic Resonance Imaging (MRI) counts, as a determination of brain size. The data are in the rda file `braintdata.rda` at the sites referenced in the Preface. For this exercise, consider the MRI counts.

- (a) Load the rda file `braintdata.rda` and print the MRI data, using the code:
`mri <- braintdata[,7]; print(mri).`
- (b) Obtain a histogram of the data, `hist(mri,pr=T)`. Comment on the shape.
- (c) Overlay the default density estimator, `lines(density(mri))`. Comment on the shape.

- (d) Obtain the sample mean and standard deviation and on the histogram overlay the normal pdf with these estimates as parameters, using `mris=sort(mri)` and `lines(dnorm(mris,mean(mris),sd(mris))~mris,lty=2)`. Comment on the fit.
- (e) Determine the proportions of the data within 1 and 2 standard deviations of the sample mean and compare these with the empirical rule.

4.1.11. This is a famous data set on the speed of light recorded by the scientist Simon Newcomb. The data set was obtained at the Carnegie Melon site given in Exercise 4.1.10 and it can also be found in the rda file `speedlight.rda` at the sites referenced in the Preface. Stigler (1977) presents an informative discussion of this data set.

- (a) Load the rda file and type the command `print(speed)`. As Stigler notes, the data values $\times 10^{-3} + 24.8$ are Newcomb's data values; hence, negative items can occur. Also, in the unit of the data the "true value" is 33.02. Discuss the data.
- (b) Obtain a histogram of the data. Comment on the shape.
- (c) On the histogram overlay the default density estimator. Comment on the shape.
- (d) Obtain the sample mean and standard deviation and on the histogram overlay the normal pdf with these estimates as parameters. Comment on the fit.
- (e) Determine the proportions of the data within 1 and 2 standard deviations of the sample mean and compare these with the empirical rule.

4.2 Confidence Intervals

Let us continue with the statistical problem that we were discussing in Section 4.1. Recall that the random variable of interest X has density $f(x; \theta), \theta \in \Omega$, where θ is unknown. In that section, we discussed estimating θ by a statistic $\hat{\theta} = \hat{\theta}(X_1, \dots, X_n)$, where X_1, \dots, X_n is a sample from the distribution of X . When the sample is drawn, it is unlikely that the value of $\hat{\theta}$ is the true value of the parameter. In fact, if $\hat{\theta}$ has a continuous distribution, then $P_\theta(\hat{\theta} = \theta) = 0$, where the notation P_θ denotes that the probability is computed when θ is the true parameter. What is needed is an estimate of the error of the estimation; i.e., by how much did $\hat{\theta}$ miss θ ? In this section, we embody this estimate of error in terms of a confidence interval, which we now formally define:

Definition 4.2.1 (Confidence Interval). *Let X_1, X_2, \dots, X_n be a sample on a random variable X , where X has pdf $f(x; \theta)$, $\theta \in \Omega$. Let $0 < \alpha < 1$ be specified. Let $L = L(X_1, X_2, \dots, X_n)$ and $U = U(X_1, X_2, \dots, X_n)$ be two statistics. We say that the interval (L, U) is a $(1 - \alpha)100\%$ confidence interval for θ if*

$$1 - \alpha = P_\theta[\theta \in (L, U)]. \quad (4.2.1)$$

That is, the probability that the interval includes θ is $1 - \alpha$, which is called the **confidence coefficient** or the **confidence level** of the interval.

Once the sample is drawn, the realized value of the confidence interval is (l, u) , an interval of real numbers. Either the interval (l, u) traps θ or it does not. One way of thinking of a confidence interval is in terms of a Bernoulli trial with probability of success $1 - \alpha$. If one makes, say, M independent $(1 - \alpha)100\%$ confidence intervals over a period of time, then one would expect to have $(1 - \alpha)M$ successful confidence intervals (those that trap θ) over this period of time. Hence one feels $(1 - \alpha)100\%$ confident that the true value of θ lies in the interval (l, u) .

A measure of efficiency based on a confidence interval is its expected length. Suppose (L_1, U_1) and (L_2, U_2) are two confidence intervals for θ that have the same confidence coefficient. Then we say that (L_1, U_1) is more efficient than (L_2, U_2) if $E_\theta(U_1 - L_1) \leq E_\theta(U_2 - L_2)$ for all $\theta \in \Omega$.

There are several procedures for obtaining confidence intervals. We explore one of them in this section. It is based on a pivot random variable. The pivot is usually a function of an estimator of θ and the parameter and, further, the distribution of the pivot is known. Using this information, an algebraic derivation can often be used to obtain a confidence interval. The next several examples illustrate the pivot method. A second way to obtain a confidence interval involves distribution free techniques, as used in Section 4.4.2 to determine confidence intervals for quantiles.

Example 4.2.1 (Confidence Interval for μ Under Normality). Suppose the random variables X_1, \dots, X_n are a random sample from a $N(\mu, \sigma^2)$ distribution. Let \bar{X} and S^2 denote the sample mean and sample variance, respectively. Recall from the last section that \bar{X} is the mle of μ and $[(n-1)/n]S^2$ is the mle of σ^2 . By part (d) of Theorem 3.6.1, the random variable $T = (\bar{X} - \mu)/(S/\sqrt{n})$ has a t -distribution with $n-1$ degrees of freedom. The random variable T is our pivot variable.

For $0 < \alpha < 1$, define $t_{\alpha/2, n-1}$ to be the upper $\alpha/2$ critical point of a t -distribution with $n-1$ degrees of freedom; i.e., $\alpha/2 = P(T > t_{\alpha/2, n-1})$. Using a simple algebraic derivation, we obtain

$$\begin{aligned} 1 - \alpha &= P(-t_{\alpha/2, n-1} < T < t_{\alpha/2, n-1}) \\ &= P_\mu \left(-t_{\alpha/2, n-1} < \frac{\bar{X} - \mu}{S/\sqrt{n}} < t_{\alpha/2, n-1} \right) \\ &= P_\mu \left(-t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \bar{X} - \mu < t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} \right) \\ &= P_\mu \left(\bar{X} - t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/2, n-1} \frac{S}{\sqrt{n}} \right). \end{aligned} \quad (4.2.2)$$

Once the sample is drawn, let \bar{x} and s denote the realized values of the statistics \bar{X} and S , respectively. Then a $(1 - \alpha)100\%$ confidence interval for μ is given by

$$(\bar{x} - t_{\alpha/2, n-1}s/\sqrt{n}, \bar{x} + t_{\alpha/2, n-1}s/\sqrt{n}). \quad (4.2.3)$$

This interval is often referred to as the $(1 - \alpha)100\%$ **t -interval** for μ . The estimate of the standard deviation of \bar{X} , s/\sqrt{n} , is referred to as the **standard error** of \bar{X} .

In Example 4.1.3, we presented a data set on sulfur dioxide concentrations in a damaged Bavarian forest. Let μ denote the true mean sulfur dioxide concentration. Recall, based on the data, that our estimate of μ is $\bar{x} = 53.92$ with sample standard deviation $s = \sqrt{101.48} = 10.07$. Since the sample size is $n = 24$, for a 99% confidence interval the t -critical value is $t_{0.005,23} = qt(.995, 23) = 2.807$. Based on these values, the confidence interval in expression (4.2.3) can be calculated. Assuming that the R vector `sulfurdioxide` contains the sample, the R code to compute this interval is `t.test(sulfurdioxide, conf.level=0.99)`, which results in the 99% confidence interval (48.14, 59.69). Many scientists write this interval as 53.92 ± 5.78 . In this way, we can see our estimate of μ and the margin of error. ■

The distribution of the pivot random variable $T = (\bar{X} - \mu)/(s/\sqrt{n})$ of the last example depends on the normality of the sampled items; however, this is approximately true even if the sampled items are not drawn from a normal distribution. The **Central Limit Theorem** (CLT) shows that the distribution of T is approximately $N(0, 1)$. In order to use this result now, we state the CLT now, leaving its proof to Chapter 5; see Theorem 5.3.1.

Theorem 4.2.1 (Central Limit Theorem). *Let X_1, X_2, \dots, X_n denote the observations of a random sample from a distribution that has mean μ and finite variance σ^2 . Then the distribution function of the random variable $W_n = (\bar{X} - \mu)/(\sigma/\sqrt{n})$ converges to Φ , the distribution function of the $N(0, 1)$ distribution, as $n \rightarrow \infty$.*

As we further show in Chapter 5, the result stays the same if we replace σ by the sample standard deviation S ; that is, under the assumptions of Theorem 4.2.1, the distribution of

$$Z_n = \frac{\bar{X} - \mu}{S/\sqrt{n}} \quad (4.2.4)$$

is approximately $N(0, 1)$. For the nonnormal case, as the next example shows, with this result we can obtain an approximate confidence interval for μ .

Example 4.2.2 (Large Sample Confidence Interval for the Mean μ). Suppose X_1, X_2, \dots, X_n is a random sample on a random variable X with mean μ and variance σ^2 , but, unlike the last example, the distribution of X is not normal. However, from the above discussion we know that the distribution of Z_n , (4.2.4), is approximately $N(0, 1)$. Hence

$$1 - \alpha \approx P_\mu \left(-z_{\alpha/2} < \frac{\bar{X} - \mu}{S/\sqrt{n}} < z_{\alpha/2} \right).$$

Using the same algebraic derivation as in the last example, we obtain

$$1 - \alpha \approx P_\mu \left(\bar{X} - z_{\alpha/2} \frac{S}{\sqrt{n}} < \mu < \bar{X} + z_{\alpha/2} \frac{S}{\sqrt{n}} \right). \quad (4.2.5)$$

Again, letting \bar{x} and s denote the realized values of the statistics \bar{X} and S , respectively, after the sample is drawn, an approximate $(1 - \alpha)100\%$ confidence interval for μ is given by

$$(\bar{x} - z_{\alpha/2}s/\sqrt{n}, \bar{x} + z_{\alpha/2}s/\sqrt{n}). \quad (4.2.6)$$

This is called a **large sample** confidence interval for μ . ■

In practice, we often do not know if the population is normal. Which confidence interval should we use? Generally, for the same α , the intervals based on $t_{\alpha/2, n-1}$ are larger than those based on $z_{\alpha/2}$. Hence the interval (4.2.3) is generally more conservative than the interval (4.2.6). So in practice, statisticians generally prefer the interval (4.2.3).

Occasionally in practice, the standard deviation σ is assumed known. In this case, the confidence interval generally used for μ is (4.2.6) with s replaced by σ .

Example 4.2.3 (Large Sample Confidence Interval for p). Let X be a Bernoulli random variable with probability of success p , where X is 1 or 0 if the outcome is success or failure, respectively. Suppose X_1, \dots, X_n is a random sample from the distribution of X . Let $\hat{p} = \bar{X}$ be the sample proportion of successes. Note that $\hat{p} = n^{-1} \sum_{i=1}^n X_i$ is a sample average and that $\text{Var}(\hat{p}) = p(1-p)/n$. It follows immediately from the CLT that the distribution of $Z = (\hat{p} - p)/\sqrt{p(1-p)/n}$ is approximately $N(0, 1)$. Referring to Example 5.1.1 of Chapter 5, we replace $p(1-p)$ with its estimate $\hat{p}(1-\hat{p})$. Then proceeding as in the last example, an approximate $(1 - \alpha)100\%$ confidence interval for p is given by

$$(\hat{p} - z_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n}, \hat{p} + z_{\alpha/2} \sqrt{\hat{p}(1-\hat{p})/n}), \quad (4.2.7)$$

where $\sqrt{\hat{p}(1-\hat{p})/n}$ is called the standard error of \hat{p} .

In Example 4.1.2 we discussed a data set involving hip replacements, some of which were squeaky. The outcomes of a hip replacement were squeaky and non-squeaky which we labeled as success or failure, respectively. In the sample there were 28 successes out of 143 replacements. Using R, the 99% confidence interval for p , the probability of a squeaky hip replacement, is computed by `prop.test(28, 143, conf.level=.99)`, which results in the interval (0.122, 0.298). So with 99% confidence, we estimate the probability of a squeaky hip replacement to be between 0.122 and 0.298. ■

4.2.1 Confidence Intervals for Difference in Means

A practical problem of interest is the comparison of two distributions, that is, comparing the distributions of two random variables, say X and Y . In this section, we compare the means of X and Y . Denote the means of X and Y by μ_1 and μ_2 , respectively. In particular, we obtain confidence intervals for the difference $\Delta = \mu_1 - \mu_2$. Assume that the variances of X and Y are finite and denote them as $\sigma_1^2 = \text{Var}(X)$ and $\sigma_2^2 = \text{Var}(Y)$. Let X_1, \dots, X_{n_1} be a random sample from the distribution of X and let Y_1, \dots, Y_{n_2} be a random sample from the distribution of Y . Assume that the samples were gathered independently of one another. Let $\bar{X} = n_1^{-1} \sum_{i=1}^{n_1} X_i$ and $\bar{Y} = n_2^{-1} \sum_{i=1}^{n_2} Y_i$ be the sample means. Let $\hat{\Delta} = \bar{X} - \bar{Y}$. The statistic $\hat{\Delta}$ is an unbiased estimator of Δ . This difference, $\hat{\Delta} - \Delta$, is the numerator of the pivot random variable. By independence of the samples,

$$\text{Var}(\hat{\Delta}) = \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}.$$

Let $S_1^2 = (n_1 - 1)^{-1} \sum_{i=1}^{n_1} (X_i - \bar{X})^2$ and $S_2^2 = (n_2 - 1)^{-1} \sum_{i=1}^{n_2} (Y_i - \bar{Y})^2$ be the sample variances. Then estimating the variances by the sample variances, consider the random variable

$$Z = \frac{\hat{\Delta} - \Delta}{\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}}. \quad (4.2.8)$$

By the independence of the samples and Theorem 4.2.1, this pivot variable has an approximate $N(0, 1)$ distribution. This leads to the approximate $(1 - \alpha)100\%$ confidence interval for $\Delta = \mu_1 - \mu_2$ given by

$$\left((\bar{x} - \bar{y}) - z_{\alpha/2} \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}, (\bar{x} - \bar{y}) + z_{\alpha/2} \sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}} \right), \quad (4.2.9)$$

where $\sqrt{(s_1^2/n_1) + (s_2^2/n_2)}$ is the standard error of $\bar{X} - \bar{Y}$. This is a large sample $(1 - \alpha)100\%$ confidence interval for $\mu_1 - \mu_2$.

The above confidence interval is approximate. In this situation we can obtain exact confidence intervals if we assume that the distributions of X and Y are normal with the same variance; i.e., $\sigma_1^2 = \sigma_2^2$. Thus the distributions can differ only in location, i.e., a **location model**. Assume then that X is distributed $N(\mu_1, \sigma^2)$ and Y is distributed $N(\mu_2, \sigma^2)$, where σ^2 is the common variance of X and Y . As above, let X_1, \dots, X_{n_1} be a random sample from the distribution of X , let Y_1, \dots, Y_{n_2} be a random sample from the distribution of Y , and assume that the samples are independent of one another. Let $n = n_1 + n_2$ be the total sample size. Our estimator of Δ is $\bar{X} - \bar{Y}$. Our goal is to show that a pivot random variable, defined below, has a t -distribution, which is defined in Section 3.6.

Because \bar{X} is distributed $N(\mu_1, \sigma^2/n_1)$, \bar{Y} is distributed $N(\mu_2, \sigma^2/n_2)$, and \bar{X} and \bar{Y} are independent, we have the result

$$\frac{(\bar{X} - \bar{Y}) - (\mu_1 - \mu_2)}{\sigma \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \text{ has a } N(0, 1) \text{ distribution.} \quad (4.2.10)$$

This serves as the numerator of our T -statistic.

Let

$$S_p^2 = \frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}. \quad (4.2.11)$$

Note that S_p^2 is a weighted average of S_1^2 and S_2^2 . It is easy to see that S_p^2 is an unbiased estimator of σ^2 . It is called the **pooled estimator** of σ^2 . Also, because $(n_1 - 1)S_1^2/\sigma^2$ has a $\chi^2(n_1 - 1)$ distribution, $(n_2 - 1)S_2^2/\sigma^2$ has a $\chi^2(n_2 - 1)$ distribution, and S_1^2 and S_2^2 are independent, we have that $(n - 2)S_p^2/\sigma^2$ has a $\chi^2(n - 2)$ distribution; see Corollary 3.3.1. Finally, because S_1^2 is independent of \bar{X} and S_2^2 is independent of \bar{Y} , and the random samples are independent of each other, it follows that S_p^2 is independent of expression (4.2.10). Therefore, from the

result of Section 3.6.1 concerning Student's t -distribution, we have that

$$\begin{aligned} T &= \frac{[(\bar{X} - \bar{Y}) - (\mu_1 - \mu_2)]/\sigma\sqrt{n_1^{-1} + n_2^{-1}}}{\sqrt{(n-2)S_p^2/(n-2)\sigma^2}} \\ &= \frac{(\bar{X} - \bar{Y}) - (\mu_1 - \mu_2)}{S_p\sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \end{aligned} \quad (4.2.12)$$

has a t -distribution with $n - 2$ degrees of freedom. From this last result, it is easy to see that the following interval is an exact $(1 - \alpha)100\%$ confidence interval for $\Delta = \mu_1 - \mu_2$:

$$\left((\bar{x} - \bar{y}) - t_{(\alpha/2, n-2)} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}, (\bar{x} - \bar{y}) + t_{(\alpha/2, n-2)} s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}} \right). \quad (4.2.13)$$

A consideration of the difficulty encountered when the unknown variances of the two normal distributions are not equal is assigned to one of the exercises.

Example 4.2.4. To illustrate the pooled t -confidence interval, consider the baseball data presented in Hettmansperger and McKean (2011). It consists of 6 variables recorded on 59 professional baseball players of which 33 are hitters and 26 are pitchers. The data can be found in the file `bb.rda` located at the site listed in Chapter 1. The height in inches of a player is one of these measurements and in this example we consider the difference in heights between pitchers and hitters. Denote the true mean heights of the pitchers and hitters by μ_p and μ_h , respectively, and let $\Delta = \mu_p - \mu_h$. The sample averages of the heights are 75.19 and 72.67 inches for the pitchers and hitters, respectively. Hence, our point estimate of Δ is 2.53 inches. Assuming the file `bb.rda` has been loaded in R, the following R segment computes the 95% confidence interval for Δ :

```
hitht=height[hitpitind==1]; pitht=height[hitpitind==0]
t.test(pitht,hitht,var.equal=T)
```

The confidence interval computes to $(1.42, 3.63)$. Note that all values in the confidence interval are positive, indicating that on the average pitchers are taller than hitters. ■

Remark 4.2.1. Suppose X and Y are not normally distributed but that their distributions differ only in location. As we show in Chapter 5, the above interval, (4.2.13), is then approximate and not exact. ■

4.2.2 Confidence Interval for Difference in Proportions

Let X and Y be two independent random variables with Bernoulli distributions $b(1, p_1)$ and $b(1, p_2)$, respectively. Let us now turn to the problem of finding a confidence interval for the difference $p_1 - p_2$. Let X_1, \dots, X_{n_1} be a random sample from the distribution of X and let Y_1, \dots, Y_{n_2} be a random sample from the distribution of Y . As above, assume that the samples are independent of one another and let

$n = n_1 + n_2$ be the total sample size. Our estimator of $p_1 - p_2$ is the difference in sample proportions, which, of course, is given by $\bar{X} - \bar{Y}$. We use the traditional notation and write \hat{p}_1 and \hat{p}_2 instead of \bar{X} and \bar{Y} , respectively. Hence, from the above discussion, an interval such as (4.2.9) serves as an approximate confidence interval for $p_1 - p_2$. Here, $\sigma_1^2 = p_1(1 - p_1)$ and $\sigma_2^2 = p_2(1 - p_2)$. In the interval, we estimate these by $\hat{p}_1(1 - \hat{p}_1)$ and $\hat{p}_2(1 - \hat{p}_2)$, respectively. Thus our approximate $(1 - \alpha)100\%$ confidence interval for $p_1 - p_2$ is

$$\hat{p}_1 - \hat{p}_2 \pm z_{\alpha/2} \sqrt{\frac{\hat{p}_1(1 - \hat{p}_1)}{n_1} + \frac{\hat{p}_2(1 - \hat{p}_2)}{n_2}}. \quad (4.2.14)$$

Example 4.2.5. Kloke and McKean (2014), page 33, discuss a data set from the original clinical study of the Salk polio vaccine in 1954. At random, one group of children (Treated) received the vaccine while the other group (Control) received a placebo. Let p_c and p_T denote the true proportions of polio cases for control and treated populations, respectively. The tabled results are:

Group	No. Children	No. Polio Cases	Sample Proportion
Treated	200,745	57	0.000284
Control	201,229	199	0.000706

Note that $\hat{p}_C > \hat{p}_T$. The following R segment computes the 95% confidence interval for $p_c - p_T$:

```
prop.test(c(199,57),c(201229,200745))
```

The confidence interval is $(0.00054, 0.00087)$. All values in this interval are positive, indicating that the vaccine is effective in reducing the incidence of polio. ■

EXERCISES

4.2.1. Let the observed value of the mean \bar{X} and of the sample variance of a random sample of size 20 from a distribution that is $N(\mu, \sigma^2)$ be 81.2 and 26.5, respectively. Find respectively 90%, 95% and 99% confidence intervals for μ . Note how the lengths of the confidence intervals increase as the confidence increases.

4.2.2. Consider the data on the lifetimes of motors given in Exercise 4.1.1. Obtain a large sample 95% confidence interval for the mean lifetime of a motor.

4.2.3. Suppose we assume that X_1, X_2, \dots, X_n is a random sample from a $\Gamma(1, \theta)$ distribution.

- (a) Show that the random variable $(2/\theta) \sum_{i=1}^n X_i$ has a χ^2 -distribution with $2n$ degrees of freedom.
- (b) Using the random variable in part (a) as a pivot random variable, find a $(1 - \alpha)100\%$ confidence interval for θ .
- (c) Obtain the confidence interval in part (b) for the data of Exercise 4.1.1 and compare it with the interval you obtained in Exercise 4.2.2.

4.2.4. In Example 4.2.4, for the baseball data, we found a confidence interval for the mean difference in heights between the pitchers and hitters. In this exercise, find the pooled t 95% confidence interval for the mean difference in weights between the pitchers and hitters.

4.2.5. In the baseball data set discussed in the last exercise, it was found that out of the 59 baseball players, 15 were left-handed. Is this odd, since the proportion of left-handed males in America is about 11%? Answer by using (4.2.7) to construct a 95% approximate confidence interval for p , the proportion of left-handed professional baseball players.

4.2.6. Let \bar{X} be the mean of a random sample of size n from a distribution that is $N(\mu, 9)$. Find n such that $P(\bar{X} - 1 < \mu < \bar{X} + 1) = 0.90$, approximately.

4.2.7. Let a random sample of size 17 from the normal distribution $N(\mu, \sigma^2)$ yield $\bar{x} = 4.7$ and $s^2 = 5.76$. Determine a 90% confidence interval for μ .

4.2.8. Let \bar{X} denote the mean of a random sample of size n from a distribution that has mean μ and variance $\sigma^2 = 10$. Find n so that the probability is approximately 0.954 that the random interval $(\bar{X} - \frac{1}{2}, \bar{X} + \frac{1}{2})$ includes μ .

4.2.9. Let X_1, X_2, \dots, X_9 be a random sample of size 9 from a distribution that is $N(\mu, \sigma^2)$.

(a) If σ is known, find the length of a 95% confidence interval for μ if this interval is based on the random variable $\sqrt{9}(\bar{X} - \mu)/\sigma$.

(b) If σ is unknown, find the expected value of the length of a 95% confidence interval for μ if this interval is based on the random variable $\sqrt{9}(\bar{X} - \mu)/S$.

Hint: Write $E(S) = (\sigma/\sqrt{n-1})E[((n-1)S^2/\sigma^2)^{1/2}]$.

(c) Compare these two answers.

4.2.10. Let $X_1, X_2, \dots, X_n, X_{n+1}$ be a random sample of size $n+1$, $n > 1$, from a distribution that is $N(\mu, \sigma^2)$. Let $\bar{X} = \sum_1^n X_i/n$ and $S^2 = \sum_1^n (X_i - \bar{X})^2/(n-1)$. Find the constant c so that the statistic $c(\bar{X} - X_{n+1})/S$ has a t -distribution. If $n = 8$, determine k such that $P(\bar{X} - kS < X_9 < \bar{X} + kS) = 0.80$. The observed interval $(\bar{x} - ks, \bar{x} + ks)$ is often called an 80% **prediction interval** for X_9 .

4.2.11. Let X_1, \dots, X_n be a random sample from a $N(0, 1)$ distribution. Then the probability that the random interval $\bar{X} \pm t_{\alpha/2, n-1}(s/\sqrt{n})$ traps $\mu = 0$ is $(1 - \alpha)$. To verify this empirically, in this exercise, we simulate m such intervals and calculate the proportion that trap 0, which should be “close” to $(1 - \alpha)$.

(a) Set $n = 10$ and $m = 50$. Run the R code `mat=matrix(rnorm(m*n), ncol=n)` which generates m samples of size n from the $N(0, 1)$ distribution. Each row of the matrix `mat` contains a sample. For this matrix of samples, the function below computes the $(1 - \alpha)100\%$ confidence intervals, returning them in a $m \times 2$ matrix. Run this function on your generated matrix `mat`. What is the proportion of successful confidence intervals?

```
getcis <- function(mat,cc=.90){
  numb <- length(mat[,1]); ci <- c()
  for(j in 1:numb)
    {ci<-rbind(ci,t.test(mat[j,],conf.level=cc)$conf.int)}
  return(ci)}
```

This function is also at the site discussed in Section 1.1.

- (b) Run the following code which plots the intervals. Label the successful intervals. Comment on the variability of the lengths of the confidence intervals.

```
cis<-getcis(mat); x<-1:m
plot(c(cis[,1],cis[,2])~c(x,x),pch="",xlab="Sample",ylab="CI")
points(cis[,1]~x,pch="L");points(cis[,2]~x,pch="U"); abline(h=0)
```

- 4.2.12.** In Exercise 4.2.11, the sampling was from the $N(0, 1)$ distribution. Show, however, that setting $\mu = 0$ and $\sigma = 1$ is without loss of generality.

Hint: First, X_1, \dots, X_n is a random sample from the $N(\mu, \sigma^2)$ if and only if Z_1, \dots, Z_n is a random sample from the $N(0, 1)$, where $Z_i = (X_i - \mu)/\sigma$. Then show the confidence interval based on the Z_i 's contains 0 if and only if the confidence interval based on the X_i 's contains μ .

- 4.2.13.** Change the code in the R function `getcis` so that it also returns the vector, `ind`, where `ind[i] = 1` if the i th confidence interval is successful and 0 otherwise. Show that the empirical confidence level is `mean(ind)`.

- (a) Run 10,000 simulations for the normal setup in Exercise 4.2.11 and compute the empirical confidence level.
- (b) Run 10,000 simulations when the sampling is from the Cauchy distribution, (1.8.8), and compute the empirical confidence level. Does it differ from (a)? Note that the R code `rcauchy(k)` returns a sample of size k from this Cauchy distribution.
- (c) Note that these empirical confidence levels are proportions from samples that are independent. Hence, use the 95% confidence interval given in expression (4.2.14) to statistically investigate whether or not the true confidence levels differ. Comment.

- 4.2.14.** Let \bar{X} denote the mean of a random sample of size 25 from a gamma-type distribution with $\alpha = 4$ and $\beta > 0$. Use the Central Limit Theorem to find an approximate 0.954 confidence interval for μ , the mean of the gamma distribution.
- Hint:* Use the random variable $(\bar{X} - 4\beta)/(4\beta^2/25)^{1/2} = 5\bar{X}/2\beta - 10$.

- 4.2.15.** Let \bar{x} be the observed mean of a random sample of size n from a distribution having mean μ and known variance σ^2 . Find n so that $\bar{x} - \sigma/4$ to $\bar{x} + \sigma/4$ is an approximate 95% confidence interval for μ .

- 4.2.16.** Assume a binomial model for a certain random variable. If we desire a 90% confidence interval for p that is at most 0.02 in length, find n .

Hint: Note that $\sqrt{(y/n)(1-y/n)} \leq \sqrt{(\frac{1}{2})(1-\frac{1}{2})}$.

4.2.17. It is known that a random variable X has a Poisson distribution with parameter μ . A sample of 200 observations from this distribution has a mean equal to 3.4. Construct an approximate 90% confidence interval for μ .

4.2.18. Let X_1, X_2, \dots, X_n be a random sample from $N(\mu, \sigma^2)$, where both parameters μ and σ^2 are unknown. A **confidence interval** for σ^2 can be found as follows. We know that $(n-1)S^2/\sigma^2$ is a random variable with a $\chi^2(n-1)$ distribution. Thus we can find constants a and b so that $P((n-1)S^2/\sigma^2 < b) = 0.975$ and $P(a < (n-1)S^2/\sigma^2 < b) = 0.95$. In R, $b = \text{qchisq}(0.975, n-1)$, while $a = \text{qchisq}(0.025, n-1)$.

- (a) Show that this second probability statement can be written as

$$P((n-1)S^2/b < \sigma^2 < (n-1)S^2/a) = 0.95.$$

- (b) If $n = 9$ and $s^2 = 7.93$, find a 95% confidence interval for σ^2 .

- (c) If μ is known, how would you modify the preceding procedure for finding a confidence interval for σ^2 ?

4.2.19. Let X_1, X_2, \dots, X_n be a random sample from a gamma distribution with known parameter $\alpha = 3$ and unknown $\beta > 0$. In Exercise 4.2.14, we obtained an approximate confidence interval for β based on the Central Limit Theorem. In this exercise obtain an exact confidence interval by first obtaining the distribution of $2 \sum_1^n X_i / \beta$.

Hint: Follow the procedure outlined in Exercise 4.2.18.

4.2.20. When 100 tacks were thrown on a table, 60 of them landed point up. Obtain a 95% confidence interval for the probability that a tack of this type lands point up. Assume independence.

4.2.21. Let two independent random samples, each of size 10, from two normal distributions $N(\mu_1, \sigma^2)$ and $N(\mu_2, \sigma^2)$ yield $\bar{x} = 4.8$, $s_1^2 = 8.64$, $\bar{y} = 5.6$, $s_2^2 = 7.88$. Find a 95% confidence interval for $\mu_1 - \mu_2$.

4.2.22. Let two independent random variables, Y_1 and Y_2 , with binomial distributions that have parameters $n_1 = n_2 = 100$, p_1 , and p_2 , respectively, be observed to be equal to $y_1 = 50$ and $y_2 = 40$. Determine an approximate 90% confidence interval for $p_1 - p_2$.

4.2.23. Discuss the problem of finding a confidence interval for the difference $\mu_1 - \mu_2$ between the two means of two normal distributions if the variances σ_1^2 and σ_2^2 are known but not necessarily equal.

4.2.24. Discuss Exercise 4.2.23 when it is assumed that the variances are unknown and unequal. This is a very difficult problem, and the discussion should point out exactly where the difficulty lies. If, however, the variances are unknown but their ratio σ_1^2/σ_2^2 is a known constant k , then a statistic that is a T random variable can again be used. Why?

4.2.25. To illustrate Exercise 4.2.24, let X_1, X_2, \dots, X_9 and Y_1, Y_2, \dots, Y_{12} represent two independent random samples from the respective normal distributions $N(\mu_1, \sigma_1^2)$ and $N(\mu_2, \sigma_2^2)$. It is given that $\sigma_1^2 = 3\sigma_2^2$, but σ_2^2 is unknown. Define a random variable that has a t -distribution that can be used to find a 95% confidence interval for $\mu_1 - \mu_2$.

4.2.26. Let \bar{X} and \bar{Y} be the means of two independent random samples, each of size n , from the respective distributions $N(\mu_1, \sigma^2)$ and $N(\mu_2, \sigma^2)$, where the common variance is known. Find n such that

$$P(\bar{X} - \bar{Y} - \sigma/5 < \mu_1 - \mu_2 < \bar{X} - \bar{Y} + \sigma/5) = 0.90.$$

4.2.27. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m be two independent random samples from the respective normal distributions $N(\mu_1, \sigma_1^2)$ and $N(\mu_2, \sigma_2^2)$, where the four parameters are unknown. To construct a *confidence interval for the ratio*, σ_1^2/σ_2^2 , of the variances, form the quotient of the two independent χ^2 variables, each divided by its degrees of freedom, namely,

$$F = \frac{\frac{(m-1)S_2^2}{\sigma_2^2}/(m-1)}{\frac{(n-1)S_1^2}{\sigma_1^2}/(n-1)} = \frac{S_2^2/\sigma_2^2}{S_1^2/\sigma_1^2},$$

where S_1^2 and S_2^2 are the respective sample variances.

- (a) What kind of distribution does F have?
- (b) Critical values a and b can be found so that $P(F < b) = 0.975$ and $P(a < F < b) = 0.95$. In R, $b = \text{qf}(0.975, m-1, n-1)$, while $a = \text{qf}(0.025, m-1, n-1)$.
- (c) Rewrite the second probability statement as

$$P \left[a \frac{S_1^2}{S_2^2} < \frac{\sigma_1^2}{\sigma_2^2} < b \frac{S_1^2}{S_2^2} \right] = 0.95.$$

The observed values, s_1^2 and s_2^2 , can be inserted in these inequalities to provide a 95% confidence interval for σ_1^2/σ_2^2 .

We caution the reader on the use of this confidence interval. This interval does depend on the normality of the distributions. If the distributions of X and Y are not normal then the true confidence coefficient may be far from the nominal confidence coefficient; see, for example, page 142 of Hettmansperger and McKean (2011) for discussion.

4.3 *Confidence Intervals for Parameters of Discrete Distributions

In this section, we outline a procedure that can be used to obtain exact confidence intervals for the parameters of discrete random variables. Let X_1, X_2, \dots, X_n be a

random sample on a discrete random variable X with pmf $p(x; \theta)$, $\theta \in \Omega$, where Ω is an interval of real numbers. Let $T = T(X_1, X_2, \dots, X_n)$ be an estimator of θ with cdf $F_T(t; \theta)$. Assume that $F_T(t; \theta)$ is a nonincreasing and continuous function of θ for every t in the support of T . For a given realization of the sample, let t be the realized value of the statistic T . Let $\alpha_1 > 0$ and $\alpha_2 > 0$ be given such that $\alpha = \alpha_1 + \alpha_2 < 0.50$. Let $\underline{\theta}$ and $\bar{\theta}$ be the solutions of the equations

$$F_T(t -; \underline{\theta}) = 1 - \alpha_2 \text{ and } F_T(t; \bar{\theta}) = \alpha_1, \quad (4.3.1)$$

where T_- is the statistic whose support lags by one value of T 's support. For instance, if $t_i < t_{i+1}$ are consecutive support values of T , then $T = t_{i+1}$ if and only if $T_- = t_i$. Under these conditions, the interval $(\underline{\theta}, \bar{\theta})$ is a confidence interval for θ with confidence coefficient of at least $1 - \alpha$. We sketch a proof of this at the end of this section.

Before proceeding with discrete examples, we provide an example in the continuous case where the solution of equations (4.3.1) produces a familiar confidence interval.

Example 4.3.1. Assume X_1, \dots, X_n is a random sample from a $N(\theta, \sigma^2)$ distribution, where σ^2 is known. Let \bar{X} be the sample mean and let \bar{x} be its value for a given realization of the sample. Recall, from expression (4.2.6), that $\bar{x} \pm z_{\alpha/2}(\sigma/\sqrt{n})$ is a $(1 - \alpha)100\%$ confidence interval for θ . Assuming θ is the true mean, the cdf of \bar{X} is $F_{\bar{X}; \theta}(t) = \Phi[(t - \theta)/(\sigma/\sqrt{n})]$, where $\Phi(z)$ is the cdf of a standard normal distribution. Note for the continuous case that \bar{X}_- has the same distribution as \bar{X} . Then the first equation of (4.3.1) yields

$$\Phi[(\bar{x} - \theta)/(\sigma/\sqrt{n})] = 1 - (\alpha/2);$$

i.e.,

$$(\bar{x} - \theta)/(\sigma/\sqrt{n}) = \Phi^{-1}[1 - (\alpha/2)] = z_{\alpha/2}.$$

Solving for θ , we obtain the lower bound of the confidence interval $\bar{x} - z_{\alpha/2}(\sigma/\sqrt{n})$. Similarly, the solution of the second equation is the upper bound of the confidence interval. ■

For the discrete case, generally iterative algorithms are used to solve equations (4.3.1). In practice, the function $F_T(T; \bar{\theta})$ is often strictly decreasing and continuous in θ , so a simple algorithm often suffices. We illustrate the examples below by using the simple **bisection algorithm**, which we now briefly discuss.

Remark 4.3.1 (Bisection Algorithm). Suppose we want to solve the equation $g(x) = d$, where $g(x)$ is strictly decreasing. Assume on a given step of the algorithm that $a < b$ bracket the solution; i.e., $g(a) > d > g(b)$. Let $c = (a + b)/2$. Then on the next step of the algorithm, the new bracket values a and b are determined by

$$\begin{aligned} \text{if}(g(c) > d) \quad \text{then} \quad & \{a \leftarrow c \text{ and } b \leftarrow b\} \\ \text{if}(g(c) < d) \quad \text{then} \quad & \{a \leftarrow a \text{ and } b \leftarrow c\}. \end{aligned}$$

The algorithm continues until $|a - b| < \epsilon$, where $\epsilon > 0$ is a specified tolerance. ■

Example 4.3.2 (Confidence Interval for a Bernoulli Proportion). Let X have a Bernoulli distribution with θ as the probability of success. Let $\Omega = (0, 1)$. Suppose X_1, X_2, \dots, X_n is a random sample on X . As our point estimator of θ , we consider \bar{X} , which is the sample proportion of successes. The cdf of $n\bar{X}$ is binomial(n, θ). Thus

$$\begin{aligned} F_{\bar{X}}(\bar{x}; \theta) &= P(n\bar{X} \leq n\bar{x}) \\ &= \sum_{j=0}^{n\bar{x}} \binom{n}{j} \theta^j (1-\theta)^{n-j} \\ &= 1 - \sum_{j=n\bar{x}+1}^n \binom{n}{j} \theta^j (1-\theta)^{n-j} \\ &= 1 - \int_0^\theta \frac{n!}{(n\bar{x})![n-(n\bar{x}+1)!]} z^{n\bar{x}} (1-z)^{n-(n\bar{x}+1)} dz, \quad (4.3.2) \end{aligned}$$

where the last equality, involving the incomplete β -function, follows from Exercise 4.3.6. By the fundamental theorem of calculus and expression (4.3.2),

$$\frac{d}{d\theta} F_{\bar{X}}(\bar{x}; \theta) = -\frac{n!}{(n\bar{x})![n-(n\bar{x}+1)!]} \theta^{n\bar{x}} (1-\theta)^{n-(n\bar{x}+1)} < 0;$$

hence, $F_{\bar{X}}(\bar{x}; \theta)$ is a strictly decreasing function of θ , for each \bar{x} . Next, let $\alpha_1, \alpha_2 > 0$ be specified constants such that $\alpha_1 + \alpha_2 < 1/2$ and let $\underline{\theta}$ and $\bar{\theta}$ solve the equations

$$F_{\bar{X}}(\bar{x}-; \underline{\theta}) = 1 - \alpha_2 \quad \text{and} \quad F_{\bar{X}}(\bar{X}; \bar{\theta}) = \alpha_1. \quad (4.3.3)$$

Then $(\underline{\theta}, \bar{\theta})$ is a confidence interval for θ with confidence coefficient at least $1 - \alpha$, where $\alpha = \alpha_1 + \alpha_2$. These equations can be solved iteratively, as discussed in the following numerical illustration.

Numerical Illustration. Suppose $n = 30$ and the realization of the sample mean is $\bar{x} = 0.60$, i.e., the sample produced $n\bar{x} = 18$ successes. Take $\alpha_1 = \alpha_2 = 0.05$. Because the support of the binomial consists of integers and $n\bar{x} = 18$, we can write equations (4.3.3) as

$$\sum_{j=0}^{17} \binom{n}{j} \underline{\theta}^j (1-\underline{\theta})^{n-j} = 0.95 \quad \text{and} \quad \sum_{j=0}^{18} \binom{n}{j} \bar{\theta}^j (1-\bar{\theta})^{n-j} = 0.05. \quad (4.3.4)$$

Let $bin(n, p)$ denote a random variable with binomial distribution with parameters n and p . Because $P(bin(30, 0.4) \leq 17) = pbinom(17, 30, .4) = 0.9787$ and because $P(bin(30, 0.45) \leq 17) = pbinom(17, 30, .45) = 0.9286$, the values 0.4 and 0.45 bracket the solution to the first equation. We use these bracket values as input to the R function¹ `binomci.r` which iteratively solves the equation. The call and its output are:

```
> binomci(17, 30, .4, .45, .95);      $solution 0.4339417
```

¹Download this function at the site given in the preface.

So the solution to the first equation is $\underline{\theta} = 0.434$. In the same way, because $P(bin(30, 0.7) \leq 18) = 0.1593$ and $P(bin(30, 0.8) \leq 18) = 0.0094$, the values 0.7 and 0.8 bracket the solution to the second equation. The R segment for the solution is:

```
> binomci(18,30,.7,.8,.05); $solution 0.75047
```

Thus the confidence interval is $(0.434, 0.750)$, with a confidence of at least 90%. For comparison, the asymptotic 90% confidence interval of expression (4.2.7) is $(0.453, 0.747)$; see Exercise 4.3.2. ■

Example 4.3.3 (Confidence Interval for the Mean of a Poisson Distribution). Let X_1, X_2, \dots, X_n be a random sample on a random variable X that has a Poisson distribution with mean θ . Let $\bar{X} = n^{-1} \sum_{i=1}^n X_i$ be our point estimator of θ . As with the Bernoulli confidence interval in the last example, we can work with $n\bar{X}$, which, in this case, has a Poisson distribution with mean $n\theta$. The cdf of \bar{X} is

$$\begin{aligned} F_{\bar{X}}(\bar{x}; \theta) &= \sum_{j=0}^{n\bar{x}} e^{-n\theta} \frac{(n\theta)^j}{j!} \\ &= \frac{1}{\Gamma(n\bar{x} + 1)} \int_{n\theta}^{\infty} x^{n\bar{x}} e^{-x} dx, \end{aligned} \quad (4.3.5)$$

where the integral equation is obtained in Exercise 4.3.7. From expression (4.3.5), we immediately have

$$\frac{d}{d\theta} F_{\bar{X}}(\bar{x}; \theta) = \frac{-n}{\Gamma(n\bar{x} + 1)} (n\theta)^{n\bar{x}} e^{-n\theta} < 0.$$

Therefore, $F_{\bar{X}}(\bar{x}; \theta)$ is a strictly decreasing function of θ for every fixed \bar{x} . For a given sample, let \bar{x} be the realization of the statistic \bar{X} . Hence, as discussed above, for $\alpha_1, \alpha_2 > 0$ such that $\alpha_1 + \alpha_2 < 1/2$, the confidence interval is given by $(\underline{\theta}, \bar{\theta})$, where

$$\sum_{j=0}^{n\bar{x}-1} e^{-n\underline{\theta}} \frac{(n\underline{\theta})^j}{j!} = 1 - \alpha_2 \quad \text{and} \quad \sum_{j=0}^{n\bar{x}} e^{-n\bar{\theta}} \frac{(n\bar{\theta})^j}{j!} = \alpha_1. \quad (4.3.6)$$

The confidence coefficient of the interval $(\underline{\theta}, \bar{\theta})$ is at least $1 - \alpha = 1 - (\alpha_1 + \alpha_2)$. As with the Bernoulli proportion, these equations can be solved iteratively.

Numerical Illustration. Suppose $n = 25$ and the realized value of \bar{X} is $\bar{x} = 5$; hence, $n\bar{x} = 125$ events have occurred. We select $\alpha_1 = \alpha_2 = 0.05$. Then, by (4.3.7), our confidence interval solves the equations

$$\sum_{j=0}^{124} e^{-n\underline{\theta}} \frac{(n\underline{\theta})^j}{j!} = 0.95 \quad \text{and} \quad \sum_{j=0}^{125} e^{-n\bar{\theta}} \frac{(n\bar{\theta})^j}{j!} = 0.05. \quad (4.3.7)$$

Our R function² `poissonci.r` uses the bisection algorithm to solve these equations. Since $\text{ppois}(124, 25 * 4) = 0.9932$ and $\text{ppois}(124, 25 * 4.4) = 0.9145$, for the first equation, 4.0 and 4.4 bracket the solution. Here is the call to `poissonci.r` along with the solution (the lower bound of the confidence interval):

²Download this function at the site given in the Preface.

```
> poissonci(124,25,4,4.4,.95); $solution 4.287836
```

Since $\text{ppois}(125, 25 * 5.5) = 0.1528$ and $\text{ppois}(125, 25 * 6.0) = 0.0204$, for the second equation, 5.5 and 6.0 bracket the solution. Hence, the computation of the lower bound of the confidence interval is:

```
> poissonci(125,25,5.5,6,.05); $solution 5.800575
```

So the confidence interval is $(4.287, 5.8)$, with confidence at least 90%. Note that the confidence interval is right-skewed, similar to the Poisson distribution. ■

A brief sketch of the theory behind this confidence interval follows. Consider the general setup in the first paragraph of this section, where T is an estimator of the unknown parameter θ and $F_T(t; \theta)$ is the cdf of T . Define

$$\bar{\theta} = \sup\{\theta : F_T(T; \theta) \geq \alpha_1\} \quad (4.3.8)$$

$$\underline{\theta} = \inf\{\theta : F_T(T-; \theta) \leq 1 - \alpha_2\}. \quad (4.3.9)$$

Hence, we have

$$\theta > \bar{\theta} \Rightarrow F_T(T; \theta) \leq \alpha_1$$

$$\theta < \underline{\theta} \Rightarrow F_T(T-; \theta) \geq 1 - \alpha_2.$$

These implications lead to

$$\begin{aligned} P[\underline{\theta} < \theta < \bar{\theta}] &= 1 - P[\{\theta < \underline{\theta}\} \cup \{\theta > \bar{\theta}\}] \\ &= 1 - P[\theta < \underline{\theta}] - P[\theta > \bar{\theta}] \\ &\geq 1 - P[F_T(T-; \theta) \geq 1 - \alpha_2] - P[F_T(T; \theta) \leq \alpha_1] \\ &\geq 1 - \alpha_1 - \alpha_2, \end{aligned}$$

where the last inequality is evident from equations (4.3.8) and (4.3.9). A rigorous proof can be based on Exercise 4.8.13; see page 425 of Shao (1998) for details.

EXERCISES

4.3.1. Recall For the baseball data (`bb.rda`), 15 out of 59 ballplayers are left-handed. Let p be the probability that a professional baseball player is left-handed. Determine an exact 90% confidence interval for p . Show first that the equations to be solved are:

$$\sum_{j=0}^{14} \binom{n}{j} \underline{\theta}^j (1 - \underline{\theta})^{n-j} = 0.95 \text{ and } \sum_{j=0}^{15} \binom{n}{j} \bar{\theta}^j (1 - \bar{\theta})^{n-j} = 0.05.$$

Then do the following steps to obtain the confidence interval.

- (a) Show that 0.10 and 0.17 bracket the solution to the first equation.
- (b) Show that 0.34 and 0.38 bracket the solution to the second equation.
- (c) Then use the R function `binomci.r` to solve the equations.

4.3.2. In Example 4.3.2, verify the result for the asymptotic confidence interval for θ .

4.3.3. In Exercise 4.2.20, the large sample confidence interval was obtained for the probability that a tack tossed on a table lands point up. Find the discrete exact confidence interval for this proportion.

4.3.4. Suppose X_1, X_2, \dots, X_{10} is a random sample on a random variable X that has a Poisson distribution with mean θ . Suppose the realized value of the sample mean is 0.5; i.e., $n\bar{x} = 5$ events occurred. Suppose we want to compute the exact 90% confidence interval for θ , as determined by equations (4.3.7).

- (a) Show that 0.19 and 0.20 bracket the solution to the first equation.
- (b) Show that 1.0 and 1.1 bracket the solution to the second equation.
- (c) Then use the R function `poissonci.r` to solve the equations.

4.3.5. Consider the same setup as in Example 4.3.1 except now assume that σ^2 is unknown. Using the distribution of $(\bar{X} - \theta)/(S/\sqrt{n})$, where S is the sample standard deviation, set up the equations and derive the t -interval, (4.2.3), for θ .

4.3.6. Using Exercise 3.3.22, show that

$$\int_0^p \frac{n!}{(k-1)!(n-k)!} z^{k-1} (1-z)^{n-k} dz = \sum_{w=k}^n \binom{n}{w} p^w (1-p)^{n-w},$$

where $0 < p < 1$, and k and n are positive integers such that $k \leq n$.

Hint: Differentiate both sides with respect to p . The derivative of the right side is a sum of differences. Show it simplifies to the derivative of the left side. Hence, the sides differ by a constant. Finally, show that the constant is 0.

4.3.7. This exercise obtains a useful identity for the cdf of a Poisson cdf.

- (a) Use Exercise 3.3.5 to show that this identity is true:

$$\frac{\lambda^n}{\Gamma(n)} \int_1^\infty x^{n-1} e^{-x\lambda} dx = \sum_{j=0}^{n-1} e^{-\lambda} \frac{\lambda^j}{j!},$$

for $\lambda > 0$ and n a positive integer.

Hint: Just consider a Poisson process on the unit interval with mean λ . Let W_n be the waiting time until the n th event. Then the left side is $P(W_n > 1)$. Why?

- (b) Obtain the identity used in Example 4.3.3, by making the transformation $z = \lambda x$ in the above integral.

4.4 Order Statistics

In this section the notion of an **order statistic** is defined and some of its simple properties are investigated. These statistics have in recent times come to play an

important role in statistical inference partly because some of their properties do not depend upon the distribution from which the random sample is obtained.

Let X_1, X_2, \dots, X_n denote a random sample from a distribution of the *continuous type* having a pdf $f(x)$ that has support $\mathcal{S} = (a, b)$, where $-\infty \leq a < b \leq \infty$. Let Y_1 be the smallest of these X_i , Y_2 the next X_i in order of magnitude, \dots , and Y_n the largest of X_i . That is, $Y_1 < Y_2 < \dots < Y_n$ represent X_1, X_2, \dots, X_n when the latter are arranged in ascending order of magnitude. We call Y_i , $i = 1, 2, \dots, n$, the i th **order statistic** of the random sample X_1, X_2, \dots, X_n . Then the joint pdf of Y_1, Y_2, \dots, Y_n is given in the following theorem.

Theorem 4.4.1. *Using the above notation, let $Y_1 < Y_2 < \dots < Y_n$ denote the n order statistics based on the random sample X_1, X_2, \dots, X_n from a continuous distribution with pdf $f(x)$ and support (a, b) . Then the joint pdf of Y_1, Y_2, \dots, Y_n is given by*

$$g(y_1, y_2, \dots, y_n) = \begin{cases} n!f(y_1)f(y_2)\cdots f(y_n) & a < y_1 < y_2 < \dots < y_n < b \\ 0 & \text{elsewhere.} \end{cases} \quad (4.4.1)$$

Proof. Note that the support of X_1, X_2, \dots, X_n can be partitioned into $n!$ mutually disjoint sets that map onto the support of Y_1, Y_2, \dots, Y_n , namely, $\{(y_1, y_2, \dots, y_n) : a < y_1 < y_2 < \dots < y_n < b\}$. One of these $n!$ sets is $a < x_1 < x_2 < \dots < x_n < b$, and the others can be found by permuting the n x s in all possible ways. The transformation associated with the one listed is $x_1 = y_1, x_2 = y_2, \dots, x_n = y_n$, which has a Jacobian equal to 1. However, the Jacobian of each of the other transformations is either ± 1 . Thus

$$\begin{aligned} g(y_1, y_2, \dots, y_n) &= \sum_{i=1}^{n!} |J_i| f(y_1)f(y_2)\cdots f(y_n) \\ &= \begin{cases} n!f(y_1)f(y_2)\cdots f(y_n) & a < y_1 < y_2 < \dots < y_n < b \\ 0 & \text{elsewhere,} \end{cases} \end{aligned}$$

as was to be proved. ■

Example 4.4.1. Let X denote a random variable of the continuous type with a pdf $f(x)$ that is positive and continuous, with support $\mathcal{S} = (a, b)$, $-\infty \leq a < b \leq \infty$. The distribution function $F(x)$ of X may be written

$$F(x) = \int_a^x f(w) dw, \quad a < x < b.$$

If $x \leq a$, $F(x) = 0$; and if $b \leq x$, $F(x) = 1$. Thus there is a unique median m of the distribution with $F(m) = \frac{1}{2}$. Let X_1, X_2, X_3 denote a random sample from this distribution and let $Y_1 < Y_2 < Y_3$ denote the order statistics of the sample. Note that Y_2 is the sample median. We compute the probability that $Y_2 \leq m$. The joint pdf of the three order statistics is

$$g(y_1, y_2, y_3) = \begin{cases} 6f(y_1)f(y_2)f(y_3) & a < y_1 < y_2 < y_3 < b \\ 0 & \text{elsewhere.} \end{cases}$$

The pdf of Y_2 is then

$$\begin{aligned} h(y_2) &= 6f(y_2) \int_{y_2}^b \int_a^{y_2} f(y_1)f(y_3) dy_1 dy_3 \\ &= \begin{cases} 6f(y_2)F(y_2)[1 - F(y_2)] & a < y_2 < b \\ 0 & \text{elsewhere.} \end{cases} \end{aligned}$$

Accordingly,

$$\begin{aligned} P(Y_2 \leq m) &= 6 \int_a^m \{F(y_2)f(y_2) - [F(y_2)]^2 f(y_2)\} dy_2 \\ &= 6 \left\{ \frac{[F(y_2)]^2}{2} - \frac{[F(y_2)]^3}{3} \right\}_a^m = \frac{1}{2}. \end{aligned}$$

Hence, for this situation, the median of the sample median Y_2 is the population median m . ■

Once it is observed that

$$\int_a^x [F(w)]^{\alpha-1} f(w) dw = \frac{[F(x)]^\alpha}{\alpha}, \quad \alpha > 0,$$

and that

$$\int_y^b [1 - F(w)]^{\beta-1} f(w) dw = \frac{[1 - F(y)]^\beta}{\beta}, \quad \beta > 0,$$

it is easy to express the marginal pdf of any order statistic, say Y_k , in terms of $F(x)$ and $f(x)$. This is done by evaluating the integral

$$g_k(y_k) = \int_a^{y_k} \cdots \int_a^{y_2} \int_{y_k}^b \cdots \int_{y_{n-1}}^b n! f(y_1)f(y_2) \cdots f(y_n) dy_n \cdots dy_{k+1} dy_1 \cdots dy_{k-1}.$$

The result is

$$g_k(y_k) = \begin{cases} \frac{n!}{(k-1)!(n-k)!} [F(y_k)]^{k-1} [1 - F(y_k)]^{n-k} f(y_k) & a < y_k < b \\ 0 & \text{elsewhere.} \end{cases} \quad (4.4.2)$$

Example 4.4.2. Let $Y_1 < Y_2 < Y_3 < Y_4$ denote the order statistics of a random sample of size 4 from a distribution having pdf

$$f(x) = \begin{cases} 2x & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

We express the pdf of Y_3 in terms of $f(x)$ and $F(x)$ and then compute $P(\frac{1}{2} < Y_3)$. Here $F(x) = x^2$, provided that $0 < x < 1$, so that

$$g_3(y_3) = \begin{cases} \frac{4!}{2! 1!} (y_3^2)^2 (1 - y_3^2) (2y_3) & 0 < y_3 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Thus

$$\begin{aligned} P\left(\frac{1}{2} < Y_3\right) &= \int_{1/2}^{\infty} g_3(y_3) dy_3 \\ &= \int_{1/2}^1 24(y_3^5 - y_3^7) dy_3 = \frac{243}{256}. \end{aligned}$$

Finally, the joint pdf of any two order statistics, say $Y_i < Y_j$, is easily expressed in terms of $F(x)$ and $f(x)$. We have

$$\begin{aligned} g_{ij}(y_i, y_j) &= \int_a^{y_i} \cdots \int_a^{y_2} \int_{y_i}^{y_j} \cdots \int_{y_{j-2}}^{y_j} \int_{y_j}^b \cdots \int_{y_{n-1}}^b n! f(y_1) \times \cdots \\ &\quad \times f(y_n) dy_n \cdots dy_{j+1} dy_{j-1} \cdots dy_{i+1} dy_1 \cdots dy_{i-1}. \end{aligned}$$

Since, for $\gamma > 0$,

$$\begin{aligned} \int_x^y [F(y) - F(w)]^{\gamma-1} f(w) dw &= -\frac{[F(y) - F(w)]^\gamma}{\gamma} \Big|_x^y \\ &= \frac{[F(y) - F(x)]^\gamma}{\gamma}, \end{aligned}$$

it is found that

$$g_{ij}(y_i, y_j) = \begin{cases} \frac{n!}{(i-1)!(j-i-1)!(n-j)!} [F(y_i)]^{i-1} [F(y_j) - F(y_i)]^{j-i-1} \\ \quad \times [1 - F(y_j)]^{n-j} f(y_i) f(y_j) & a < y_i < y_j < b \\ 0 & \text{elsewhere.} \end{cases} \quad (4.4.3)$$

Remark 4.4.1 (Heuristic Derivation). There is an easy method of remembering the pdf of a vector of order statistics such as the one given in formula (4.4.3). The probability $P(y_i < Y_i < y_i + \Delta_i, y_j < Y_j < y_j + \Delta_j)$, where Δ_i and Δ_j are small, can be approximated by the following multinomial probability. In n independent trials, $i-1$ outcomes must be less than y_i [an event that has probability $p_1 = F(y_i)$ on each trial]; $j-i-1$ outcomes must be between $y_i + \Delta_i$ and y_j [an event with approximate probability $p_2 = F(y_j) - F(y_i)$ on each trial]; $n-j$ outcomes must be greater than $y_j + \Delta_j$ [an event with approximate probability $p_3 = 1 - F(y_j)$ on each trial]; one outcome must be between y_i and $y_i + \Delta_i$ [an event with approximate probability $p_4 = f(y_i)\Delta_i$ on each trial]; and, finally, one outcome must be between y_j and $y_j + \Delta_j$ [an event with approximate probability $p_5 = f(y_j)\Delta_j$ on each trial]. This multinomial probability is

$$\frac{n!}{(i-1)!(j-i-1)!(n-j)! 1! 1!} p_1^{i-1} p_2^{j-i-1} p_3^{n-j} p_4 p_5,$$

which is $g_{i,j}(y_i, y_j)\Delta_i\Delta_j$, where $g_{i,j}(y_i, y_j)$ is given in expression (4.4.3). ■

Certain functions of the order statistics Y_1, Y_2, \dots, Y_n are important statistics themselves. The **sample range** of the random sample is given by $Y_n - Y_1$ and the **sample midrange** is given by $(Y_1 + Y_n)/2$, which is called the **midrange** of the random sample. The **sample median** of the random sample is defined by

$$Q_2 = \begin{cases} Y_{(n+1)/2} & \text{if } n \text{ is odd} \\ (Y_{n/2} + Y_{(n/2)+1})/2 & \text{if } n \text{ is even.} \end{cases} \quad (4.4.4)$$

Example 4.4.3. Let Y_1, Y_2, Y_3 be the order statistics of a random sample of size 3 from a distribution having pdf

$$f(x) = \begin{cases} 1 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

We seek the pdf of the sample range $Z_1 = Y_3 - Y_1$. Since $F(x) = x$, $0 < x < 1$, the joint pdf of Y_1 and Y_3 is

$$g_{13}(y_1, y_3) = \begin{cases} 6(y_3 - y_1) & 0 < y_1 < y_3 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

In addition to $Z_1 = Y_3 - Y_1$, let $Z_2 = Y_3$. The functions $z_1 = y_3 - y_1$, $z_2 = y_3$ have respective inverses $y_1 = z_2 - z_1$, $y_3 = z_2$, so that the corresponding Jacobian of the one-to-one transformation is

$$J = \begin{vmatrix} \frac{\partial y_1}{\partial z_1} & \frac{\partial y_1}{\partial z_2} \\ \frac{\partial y_3}{\partial z_1} & \frac{\partial y_3}{\partial z_2} \end{vmatrix} = \begin{vmatrix} -1 & 1 \\ 0 & 1 \end{vmatrix} = -1.$$

Thus the joint pdf of Z_1 and Z_2 is

$$h(z_1, z_2) = \begin{cases} -1/6z_1 & 0 < z_1 < z_2 < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Accordingly, the pdf of the range $Z_1 = Y_3 - Y_1$ of the random sample of size 3 is

$$h_1(z_1) = \begin{cases} \int_{z_1}^1 6z_1 dz_2 = 6z_1(1 - z_1) & 0 < z_1 < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad \blacksquare$$

4.4.1 Quantiles

Let X be a random variable with a continuous cdf $F(x)$. For $0 < p < 1$, define the **pth quantile** of X to be $\xi_p = F^{-1}(p)$. For example, $\xi_{0.5}$, the median of X , is the 0.5 quantile. Let X_1, X_2, \dots, X_n be a random sample from the distribution of X and let $Y_1 < Y_2 < \dots < Y_n$ be the corresponding order statistics. Let k be the greatest integer less than or equal to $[p(n+1)]$. We next define an estimator of ξ_p after making the following observation. The area under the pdf $f(x)$ to the left of Y_k is $F(Y_k)$. The expected value of this area is

$$E(F(Y_k)) = \int_a^b F(y_k) g_k(y_k) dy_k,$$

where $g_k(y_k)$ is the pdf of Y_k given in expression (4.4.2). If, in this integral, we make a change of variables through the transformation $z = F(y_k)$, we have

$$E(F(Y_k)) = \int_0^1 \frac{n!}{(k-1)!(n-k)!} z^k (1-z)^{n-k} dz.$$

Comparing this to the integral of a beta pdf, we see that it is equal to

$$E(F(Y_k)) = \frac{n!k!(n-k)!}{(k-1)!(n-k)!(n+1)!} = \frac{k}{n+1}.$$

On the average, there is $k/(n+1)$ of the total area to the left of Y_k . Because $p = k/(n+1)$, it seems reasonable to take Y_k as an estimator of the quantile ξ_p . Hence, we call Y_k the **p th sample quantile**. It is also called the **100 p th percentile of the sample**.

Remark 4.4.2. Some statisticians define sample quantiles slightly differently from what we have. For one modification with $1/(n+1) < p < n/(n+1)$, if $(n+1)/p$ is not equal to an integer, then the p th quantile of the sample may be defined as follows. Write $(n+1)p = k + r$, where $k = [(n+1)p]$ and r is a proper fraction, using the weighted average. Then the p th quantile of the sample is the weighted average

$$(1-r)Y_k + rY_{k+1}, \quad (4.4.5)$$

which is an estimator of the p th quantile. As n becomes large, however, all these modified definitions are essentially the same. For R code, let the R vector x contain the realization of the sample. Then the call `quantile(x, p)` computes a p th quantile of form (4.4.5). ■

Sample quantiles are useful descriptive statistics. For instance, if y_k is the p th quantile of the realized sample, then we know that approximately $p100\%$ of the data are less than or equal to y_k and approximately $(1-p)100\%$ of the data are greater than or equal to y_k . Next we discuss two statistical applications of quantiles.

A **five-number** summary of the data consists of the following five sample quantiles: the minimum (Y_1), the first quartile ($Y_{.25(n+1)}$), the median defined in expression (4.4.4), the third quartile ($Y_{.75(n+1)}$), and the maximum (Y_n). For this section, we use the notation Q_1 , Q_2 , and Q_3 to denote, respectively, the first quartile, median, and third quartile of the sample.

The five-number summary divides the data into their quartiles, offering a simple and easily interpretable description of the data. Five-number summaries were made popular by the work of the late Professor John Tukey [see Tukey (1977) and Mosteller and Tukey (1977)]. Tukey used the median of the lower half of the data (from minimum to median) and the median of the upper half of the data instead of the first and third quartiles. He referred to these quantities as the **hinges** of the data. The R function `fivenum(x)` returns the hinges along with the minimum, median, and maximum of the data.

Example 4.4.4. The following data are the ordered realizations of a random sample of size 15 on a random variable X .

56	70	89	94	96	101	102	102
102	105	106	108	110	113	116	

For these data, since $n + 1 = 16$, the realizations of the five-number summary are $y_1 = 56$, $Q_1 = y_4 = 94$, $Q_2 = y_8 = 102$, $Q_3 = y_{12} = 108$, and $y_{15} = 116$. Hence, based on the five-number summary, the data range from 56 to 116; the middle 50% of the data range from 94 to 108; and the middle of the data occurred at 102. The data are in the file `eg4.4.4data.rda`. ■

The five-number summary is the basis for a useful and quick plot of the data. This is called a **boxplot** of the data. The box encloses the middle 50% of the data and a line segment is usually used to indicate the median. The extreme order statistics, however, are very sensitive to outlying points. So care must be used in placing these on the plot. We make use of the **box and whisker** plots defined by John Tukey. In order to define this plot, we need to define a potential outlier. Let $h = 1.5(Q_3 - Q_1)$ and define the **lower fence** (LF) and the **upper fence** (UF) by

$$LF = Q_1 - h \text{ and } UF = Q_3 + h. \quad (4.4.6)$$

Points that lie outside the fences, i.e., outside the interval (LF, UF) , are called **potential outliers** and they are denoted by the symbol “0” on the boxplot. The whiskers then protrude from the sides of the box to what are called the **adjacent points**, which are the points within the fences but closest to the fences. Exercise 4.4.2 shows that the probability of an observation from a normal distribution being a potential outlier is 0.006977.

Example 4.4.5 (Example 4.4.4, Continued). Consider the data given in Example 4.4.4. For these data, $h = 1.5(108 - 94) = 21$, $LF = 73$, and $UF = 129$. Hence the observations 56 and 70 are potential outliers. There are no outliers on the high side of the data. The lower adjacent point is 89. The boxplot of the data set is given in Panel A of Figure 4.4.1, which was computed by the R segment `boxplot(x)` where the R vector `x` contains the data.

Note that the point 56 is over $2h$ from Q_1 . Some statisticians call such a point an “outlier” and label it with a symbol other than “O,” but we do not make this distinction. ■

In practice, we often assume that the data follow a certain distribution. For example, we may assume that X_1, \dots, X_n are a random sample from a normal distribution with unknown mean and variance. Thus the form of the distribution of X is known, but the specific parameters are not. Such an assumption needs to be checked and there are many statistical tests which do so; see D'Agostino and Stephens (1986) for a thorough discussion of such tests. As our second statistical application of quantiles, we discuss one such diagnostic plot in this regard.

We consider the location and scale family. Suppose X is a random variable with cdf $F((x - a)/b)$, where $F(x)$ is known but a and $b > 0$ may not be. Let $Z = (X - a)/b$; then Z has cdf $F(z)$. Let $0 < p < 1$ and let $\xi_{X,p}$ be the p th quantile of X . Let $\xi_{Z,p}$ be the p th quantile of $Z = (X - a)/b$. Because $F(z)$ is known, $\xi_{Z,p}$ is known. But

$$p = P[X \leq \xi_{X,p}] = P\left[Z \leq \frac{\xi_{X,p} - a}{b}\right],$$

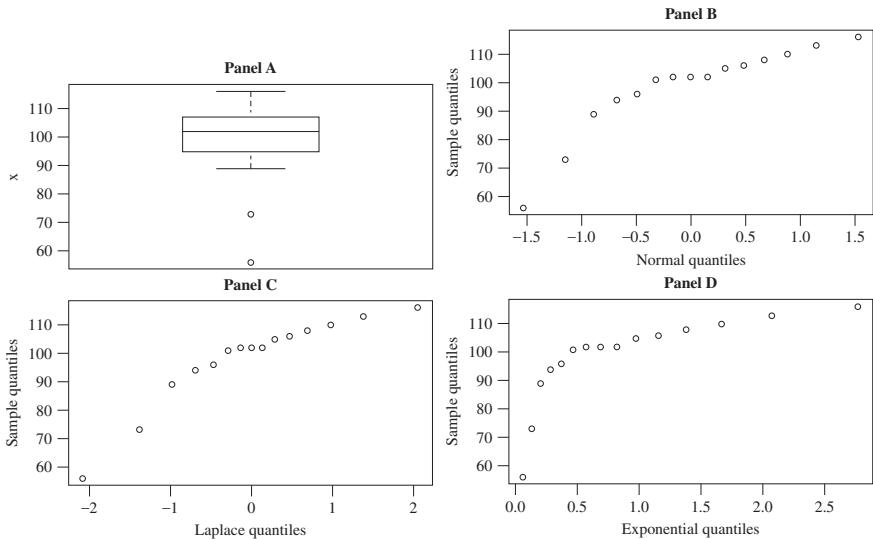

Figure 4.4.1: Boxplot and quantile plots for the data of Example 4.4.4.

from which we have the linear relationship

$$\xi_{X,p} = b\xi_{Z,p} + a. \quad (4.4.7)$$

Thus, if X has a cdf of the form of $F((x - a)/b)$, then the quantiles of X are linearly related to the quantiles of Z . Of course, in practice, we do not know the quantiles of X , but we can estimate them. Let X_1, \dots, X_n be a random sample from the distribution of X and let $Y_1 < \dots < Y_n$ be the order statistics. For $k = 1, \dots, n$, let $p_k = k/(n + 1)$. Then Y_k is an estimator of ξ_{X,p_k} . Denote the corresponding quantiles of the cdf $F(z)$ by $\xi_{Z,p_k} = F^{-1}(p_k)$. Let y_k denote the realized value of Y_k . The plot of y_k versus ξ_{Z,p_k} is called a **q-q plot**, as it plots one set of quantiles from the sample against another set from the theoretical cdf $F(z)$. Based on the above discussion, the linearity of such a plot indicates that the cdf of X is of the form $F((x - a)/b)$.

Example 4.4.6 (Example 4.4.5, Continued). Panels B, C, and D of Figure 4.4.1 contain $q-q$ plots of the data of Example 4.4.4 for three different distributions. The quantiles of a standard normal random variable are used for the plot in Panel B. Hence, as described above, this is the plot of y_k versus $\Phi^{-1}(k/(n + 1))$, for $k = 1, 2, \dots, n$. For Panel C, the population quantiles of the standard **Laplace** distribution are used; that is, the density of Z is $f(z) = (1/2)e^{-|z|}$, $-\infty < z < \infty$. For Panel D, the quantiles were generated from an exponential distribution with density $f(z) = e^{-z}$, $0 < z < \infty$, zero elsewhere. The generation of these quantiles is discussed in Exercise 4.4.1.

The plot farthest from linearity is that of Panel D. Note that this plot gives an indication of a more correct distribution. For the points to lie on a line, the

lower quantiles of Z must be spread out as are the higher quantiles; i.e., symmetric distributions may be more appropriate. The plots in Panels B and C are more linear than that of Panel D, but they still contain some curvature. Of the two, Panel C appears to be more linear. Actually, the data were generated from a Laplace distribution, so one would expect that Panel C would be the most linear of the three plots.

Many computer packages have commands to obtain the population quantiles used in this example. The R function `qqplotc4s2.r`, at the site listed in Chapter 1, obtains the normal, Laplace, and exponential quantiles used for Figure 4.4.1 and the plot. The call is `qqplotc4s2(x)` where the R vector `x` contains the data. ■

The $q-q$ plot using normal quantiles is often called a **normal** $q-q$ plot. If the data are in the R vector `x`, the plot is obtained by the call `qqnorm(x)`.

4.4.2 Confidence Intervals for Quantiles

Let X be a continuous random variable with cdf $F(x)$. For $0 < p < 1$, define the 100 p th distribution percentile to be ξ_p , where $F(\xi_p) = p$. For a sample of size n on X , let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics. Let $k = [(n+1)p]$. Then the 100 p th sample percentile Y_k is a point estimate of ξ_p .

We now derive a **distribution free** confidence interval for ξ_p , meaning it is a confidence interval for ξ_p which is free of any assumptions about $F(x)$ other than it is of the continuous type. Let $i < [(n+1)p] < j$, and consider the order statistics $Y_i < Y_j$ and the event $Y_i < \xi_p < Y_j$. For the i th order statistic Y_i to be less than ξ_p , it must be true that at least i of the X values are less than ξ_p . Moreover, for the j th order statistic to be greater than ξ_p , fewer than j of the X values are less than ξ_p . To put this in the context of a binomial distribution, the probability of success is $P(X < \xi_p) = F(\xi_p) = p$. Further, the event $Y_i < \xi_p < Y_j$ is equivalent to obtaining between i (inclusive) and j (exclusive) successes in n independent trials. Thus, taking probabilities, we have

$$P(Y_i < \xi_p < Y_j) = \sum_{w=i}^{j-1} \binom{n}{w} p^w (1-p)^{n-w}. \quad (4.4.8)$$

When particular values of n , i , and j are specified, this probability can be computed. By this procedure, suppose that it has been found that $\gamma = P(Y_i < \xi_p < Y_j)$. Then the probability is γ that the random interval (Y_i, Y_j) includes the quantile of order p . If the experimental values of Y_i and Y_j are, respectively, y_i and y_j , the interval (y_i, y_j) serves as a 100 $\gamma\%$ confidence interval for ξ_p , the quantile of order p . We use this in the next example to find a confidence interval for the median.

Example 4.4.7 (Confidence Interval for the Median). Let X be a continuous random variable with cdf $F(x)$. Let $\xi_{1/2}$ denote the median of $F(x)$; i.e., $\xi_{1/2}$ solves $F(\xi_{1/2}) = 1/2$. Suppose X_1, X_2, \dots, X_n is a random sample from the distribution of X with corresponding order statistics $Y_1 < Y_2 < \dots < Y_n$. As before, let Q_2 denote the sample median, which is a point estimator of $\xi_{1/2}$. Select α , so that $0 < \alpha < 1$. Take $c_{\alpha/2}$ to be the $\alpha/2$ th quantile of a binomial $b(n, 1/2)$ distribution;

that is, $P[S \leq c_{\alpha/2}] = \alpha/2$, where S is distributed $b(n, 1/2)$. Then note also that $P[S \geq n - c_{\alpha/2}] = \alpha/2$. (Because of the discreteness of the binomial distribution, either take a value of α for which these probabilities are correct or change the equalities to approximations.) Thus it follows from expression (4.4.8) that

$$P[Y_{c_{\alpha/2}+1} < \xi_{1/2} < Y_{n-c_{\alpha/2}}] = 1 - \alpha. \quad (4.4.9)$$

Hence, when the sample is drawn, if $y_{c_{\alpha/2}+1}$ and $y_{n-c_{\alpha/2}}$ are the realized values of the order statistics $Y_{c_{\alpha/2}+1}$ and $Y_{n-c_{\alpha/2}}$, then the interval

$$(y_{c_{\alpha/2}+1}, y_{n-c_{\alpha/2}}) \quad (4.4.10)$$

is a $(1 - \alpha)100\%$ confidence interval for $\xi_{1/2}$.

To illustrate this confidence interval, consider the data of Example 4.4.4. Suppose we want an 88% confidence interval for $\xi_{1/2}$. Then $\alpha/2 = 0.060$. Then $c_{\alpha/2} = 4$ because $P[S \leq 4] = \text{pb}inom(4, 15, .5) = 0.059$, where the distribution of S is binomial with $n = 15$ and $p = 0.5$. Therefore, an 88% confidence interval for $\xi_{1/2}$ is $(y_5, y_{11}) = (96, 106)$.

The R function `onesampsgn(x)` computes a confidence interval for the median. For the data in Example 4.4.4, the code `onesampsgn(x, alpha=.12)` computes the confidence interval $(96, 106)$ for the median. ■

Note that because of the discreteness of the binomial distribution, only certain confidence levels are possible for this confidence interval for the median. If we further assume that $f(x)$ is symmetric about ξ , Chapter 10 presents other distribution free confidence intervals where this discreteness is much less of a problem.

EXERCISES

4.4.1. Obtain closed-form expressions for the distribution quantiles based on the exponential and Laplace distributions as discussed in Example 4.4.6.

4.4.2. Suppose the pdf $f(x)$ is symmetric about 0 with cdf $F(x)$. Show that the probability of a potential outlier from this distribution is $2F(4q_1)$, where $F^{-1}(0.25) = q_1$. Use this to obtain the probability that an observation is a potential outlier for the following distributions.

- (a) The underlying distribution is normal. Use the $N(0, 1)$ distribution.
- (b) The underlying distribution is **logistic**; that is, the pdf is given by

$$f(x) = \frac{e^{-x}}{(1 + e^{-x})^2}, \quad -\infty < x < \infty. \quad (4.4.11)$$

- (c) The underlying distribution is Laplace, with the pdf

$$f(x) = \frac{1}{2}e^{-|x|}, \quad -\infty < x < \infty. \quad (4.4.12)$$

4.4.3. Consider the sample of data (data are in the file `ex4.4.3data.rda`):

13	5	202	15	99	4	67	83	36	11	301
23	213	40	66	106	78	69	166	84	64	

- (a) Obtain the five-number summary of these data.
- (b) Determine if there are any outliers.
- (c) Boxplot the data. Comment on the plot.

4.4.4. Consider the data in Exercise 4.4.3. Obtain the normal $q-q$ plot for these data. Does the plot suggest that the underlying distribution is normal? If not, use the plot to determine a more appropriate distribution. Confirm your choice with a $q-q$ based on the quantiles using your chosen distribution.

4.4.5. Let $Y_1 < Y_2 < Y_3 < Y_4$ be the order statistics of a random sample of size 4 from the distribution having pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Find $P(Y_4 \geq 3)$.

4.4.6. Let X_1, X_2, X_3 be a random sample from a distribution of the continuous type having pdf $f(x) = 2x$, $0 < x < 1$, zero elsewhere.

- (a) Compute the probability that the smallest of X_1, X_2, X_3 exceeds the median of the distribution.
- (b) If $Y_1 < Y_2 < Y_3$ are the order statistics, find the correlation between Y_2 and Y_3 .

4.4.7. Let $f(x) = \frac{1}{6}$, $x = 1, 2, 3, 4, 5, 6$, zero elsewhere, be the pmf of a distribution of the discrete type. Show that the pmf of the smallest observation of a random sample of size 5 from this distribution is

$$g_1(y_1) = \left(\frac{7-y_1}{6}\right)^5 - \left(\frac{6-y_1}{6}\right)^5, \quad y_1 = 1, 2, \dots, 6,$$

zero elsewhere. Note that in this exercise the random sample is from a distribution of the discrete type. All formulas in the text were derived under the assumption that the random sample is from a distribution of the continuous type and are not applicable. Why?

4.4.8. Let $Y_1 < Y_2 < Y_3 < Y_4 < Y_5$ denote the order statistics of a random sample of size 5 from a distribution having pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Show that $Z_1 = Y_2$ and $Z_2 = Y_4 - Y_2$ are independent.

Hint: First find the joint pdf of Y_2 and Y_4 .

4.4.9. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from a distribution with pdf $f(x) = 1$, $0 < x < 1$, zero elsewhere. Show that the k th order statistic Y_k has a beta pdf with parameters $\alpha = k$ and $\beta = n - k + 1$.

4.4.10. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics from a Weibull distribution, Exercise 3.3.26. Find the distribution function and pdf of Y_1 .

4.4.11. Find the probability that the range of a random sample of size 4 from the uniform distribution having the pdf $f(x) = 1$, $0 < x < 1$, zero elsewhere, is less than $\frac{1}{2}$.

4.4.12. Let $Y_1 < Y_2 < Y_3$ be the order statistics of a random sample of size 3 from a distribution having the pdf $f(x) = 2x$, $0 < x < 1$, zero elsewhere. Show that $Z_1 = Y_1/Y_2$, $Z_2 = Y_2/Y_3$, and $Z_3 = Y_3$ are mutually independent.

4.4.13. Suppose a random sample of size 2 is obtained from a distribution that has pdf $f(x) = 2(1-x)$, $0 < x < 1$, zero elsewhere. Compute the probability that one sample observation is at least twice as large as the other.

4.4.14. Let $Y_1 < Y_2 < Y_3$ denote the order statistics of a random sample of size 3 from a distribution with pdf $f(x) = 1$, $0 < x < 1$, zero elsewhere. Let $Z = (Y_1 + Y_3)/2$ be the midrange of the sample. Find the pdf of Z .

4.4.15. Let $Y_1 < Y_2$ denote the order statistics of a random sample of size 2 from $N(0, \sigma^2)$.

- (a) Show that $E(Y_1) = -\sigma/\sqrt{\pi}$.

Hint: Evaluate $E(Y_1)$ by using the joint pdf of Y_1 and Y_2 and first integrating on y_1 .

- (b) Find the covariance of Y_1 and Y_2 .

4.4.16. Let $Y_1 < Y_2$ be the order statistics of a random sample of size 2 from a distribution of the continuous type which has pdf $f(x)$ such that $f(x) > 0$, provided that $x \geq 0$, and $f(x) = 0$ elsewhere. Show that the independence of $Z_1 = Y_1$ and $Z_2 = Y_2 - Y_1$ characterizes the gamma pdf $f(x)$, which has parameters $\alpha = 1$ and $\beta > 0$. That is, show that Y_1 and Y_2 are independent if and only if $f(x)$ is the pdf of a $\Gamma(1, \beta)$ distribution.

Hint: Use the change-of-variable technique to find the joint pdf of Z_1 and Z_2 from that of Y_1 and Y_2 . Accept the fact that the functional equation $h(0)h(x+y) \equiv h(x)h(y)$ has the solution $h(x) = c_1 e^{c_2 x}$, where c_1 and c_2 are constants.

4.4.17. Let $Y_1 < Y_2 < Y_3 < Y_4$ be the order statistics of a random sample of size $n = 4$ from a distribution with pdf $f(x) = 2x$, $0 < x < 1$, zero elsewhere.

- (a) Find the joint pdf of Y_3 and Y_4 .

- (b) Find the conditional pdf of Y_3 , given $Y_4 = y_4$.

- (c) Evaluate $E(Y_3|y_4)$.

4.4.18. Two numbers are selected at random from the interval $(0, 1)$. If these values are uniformly and independently distributed, by cutting the interval at these numbers, compute the probability that the three resulting line segments can form a triangle.

4.4.19. Let X and Y denote independent random variables with respective probability density functions $f(x) = 2x$, $0 < x < 1$, zero elsewhere, and $g(y) = 3y^2$, $0 < y < 1$, zero elsewhere. Let $U = \min(X, Y)$ and $V = \max(X, Y)$. Find the joint pdf of U and V .

Hint: Here the two inverse transformations are given by $x = u$, $y = v$ and $x = v$, $y = u$.

4.4.20. Let the joint pdf of X and Y be $f(x, y) = \frac{12}{7}x(x+y)$, $0 < x < 1$, $0 < y < 1$, zero elsewhere. Let $U = \min(X, Y)$ and $V = \max(X, Y)$. Find the joint pdf of U and V .

4.4.21. Let X_1, X_2, \dots, X_n be a random sample from a distribution of either type. A measure of spread is *Gini's mean difference*

$$G = \sum_{j=2}^n \sum_{i=1}^{j-1} |X_i - X_j| / \binom{n}{2}. \quad (4.4.13)$$

- (a) If $n = 10$, find a_1, a_2, \dots, a_{10} so that $G = \sum_{i=1}^{10} a_i Y_i$, where Y_1, Y_2, \dots, Y_{10} are the order statistics of the sample.
- (b) Show that $E(G) = 2\sigma/\sqrt{\pi}$ if the sample arises from the normal distribution $N(\mu, \sigma^2)$.

4.4.22. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from the exponential distribution with pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere.

- (a) Show that $Z_1 = nY_1$, $Z_2 = (n-1)(Y_2 - Y_1)$, $Z_3 = (n-2)(Y_3 - Y_2)$, \dots , $Z_n = Y_n - Y_{n-1}$ are independent and that each Z_i has the exponential distribution.
- (b) Demonstrate that all linear functions of Y_1, Y_2, \dots, Y_n , such as $\sum_1^n a_i Y_i$, can be expressed as linear functions of independent random variables.

4.4.23. In the Program Evaluation and Review Technique (PERT), we are interested in the total time to complete a project that is comprised of a large number of subprojects. For illustration, let X_1, X_2, X_3 be three independent random times for three subprojects. If these subprojects are in series (the first one must be completed before the second starts, etc.), then we are interested in the sum $Y = X_1 + X_2 + X_3$. If these are in parallel (can be worked on simultaneously), then we are interested in $Z = \max(X_1, X_2, X_3)$. In the case each of these random variables has the uniform distribution with pdf $f(x) = 1$, $0 < x < 1$, zero elsewhere, find (a) the pdf of Y and (b) the pdf of Z .

4.4.24. Let Y_n denote the n th order statistic of a random sample of size n from a distribution of the continuous type. Find the smallest value of n for which the inequality $P(\xi_{0.9} < Y_n) \geq 0.75$ is true.

4.4.25. Let $Y_1 < Y_2 < Y_3 < Y_4 < Y_5$ denote the order statistics of a random sample of size 5 from a distribution of the continuous type. Compute:

- (a) $P(Y_1 < \xi_{0.5} < Y_5)$.
- (b) $P(Y_1 < \xi_{0.25} < Y_3)$.
- (c) $P(Y_4 < \xi_{0.80} < Y_5)$.

4.4.26. Compute $P(Y_3 < \xi_{0.5} < Y_7)$ if $Y_1 < \dots < Y_9$ are the order statistics of a random sample of size 9 from a distribution of the continuous type.

4.4.27. Find the smallest value of n for which $P(Y_1 < \xi_{0.5} < Y_n) \geq 0.99$, where $Y_1 < \dots < Y_n$ are the order statistics of a random sample of size n from a distribution of the continuous type.

4.4.28. Let $Y_1 < Y_2$ denote the order statistics of a random sample of size 2 from a distribution that is $N(\mu, \sigma^2)$, where σ^2 is known.

- (a) Show that $P(Y_1 < \mu < Y_2) = \frac{1}{2}$ and compute the expected value of the random length $Y_2 - Y_1$.
- (b) If \bar{X} is the mean of this sample, find the constant c that solves the equation $P(\bar{X} - c\sigma < \mu < \bar{X} + c\sigma) = \frac{1}{2}$, and compare the length of this random interval with the expected value of that of part (a).

4.4.29. Let $y_1 < y_2 < y_3$ be the observed values of the order statistics of a random sample of size $n = 3$ from a continuous type distribution. Without knowing these values, a statistician is given these values in a random order, and she wants to select the largest; but once she refuses an observation, she cannot go back. Clearly, if she selects the first one, her probability of getting the largest is $1/3$. Instead, she decides to use the following algorithm: She looks at the first but refuses it and then takes the second if it is larger than the first, or else she takes the third. Show that this algorithm has probability of $1/2$ of selecting the largest.

4.4.30. Refer to Exercise 4.1.1. Using expression (4.4.10), obtain a confidence interval (with confidence close to 90%) for the median lifetime of a motor. What does the interval mean?

4.4.31. Let $Y_1 < Y_2 < \dots < Y_n$ denote the order statistics of a random sample of size n from a distribution that has pdf $f(x) = 3x^2/\theta^3$, $0 < x < \theta$, zero elsewhere.

- (a) Show that $P(c < Y_n/\theta < 1) = 1 - c^{3n}$, where $0 < c < 1$.
- (b) If n is 4 and if the observed value of Y_4 is 2.3, what is a 95% confidence interval for θ ?

4.4.32. Reconsider the weight of professional baseball players in the data file `bb.rda`. Obtain comparison boxplots of the weights of the hitters and pitchers (use the R code `boxplot(x,y)` where `x` and `y` contain the weights of the hitters and pitchers, respectively). Then obtain 95% confidence intervals for the median weights of the hitters and pitchers (use the R function `onesampsgn`). Comment.

4.5 Introduction to Hypothesis Testing

Point estimation and confidence intervals are useful statistical inference procedures. Another type of inference that is frequently used concerns tests of hypotheses. As in Sections 4.1 through 4.3, suppose our interest centers on a random variable X that has density function $f(x; \theta)$, where $\theta \in \Omega$. Suppose we think, due to theory or a preliminary experiment, that $\theta \in \omega_0$ or $\theta \in \omega_1$, where ω_0 and ω_1 are disjoint subsets of Ω and $\omega_0 \cup \omega_1 = \Omega$. We label these hypotheses as

$$H_0 : \theta \in \omega_0 \text{ versus } H_1 : \theta \in \omega_1. \quad (4.5.1)$$

The hypothesis H_0 is referred to as the **null hypothesis**, while H_1 is referred to as the **alternative hypothesis**. Often the null hypothesis represents no change or no difference from the past, while the alternative represents change or difference. The alternative is often referred to as the research worker's hypothesis. The decision rule to take H_0 or H_1 is based on a sample X_1, \dots, X_n from the distribution of X and, hence, the decision could be wrong. For instance, we could decide that $\theta \in \omega_1$ when really $\theta \in \omega_0$ or we could decide that $\theta \in \omega_0$ when, in fact, $\theta \in \omega_1$. We label these errors Type I and Type II errors, respectively, later in this section. As we show in Chapter 8, a careful analysis of these errors can lead in certain situations to optimal decision rules. In this section, though, we simply want to introduce the elements of hypothesis testing. To set ideas, consider the following example.

Example 4.5.1 (*Zea mays* Data). In 1878 Charles Darwin recorded some data on the heights of *Zea mays* plants to determine what effect cross-fertilization or self-fertilization had on the height of *Zea mays*. The experiment was to select one cross-fertilized plant and one self-fertilized plant, grow them in the same pot, and then later measure their heights. An interesting hypothesis for this example would be that the cross-fertilized plants are generally taller than the self-fertilized plants. This is the alternative hypothesis, i.e., the research worker's hypothesis. The null hypothesis is that the plants generally grow to the same height regardless of whether they were self- or cross-fertilized. Data for 15 pots were recorded.

We represent the data as $(Y_1, Z_1), \dots, (Y_{15}, Z_{15})$, where Y_i and Z_i are the heights of the cross-fertilized and self-fertilized plants, respectively, in the i th pot. Let $X_i = Y_i - Z_i$. Due to growing in the same pot, Y_i and Z_i may be dependent random variables, but it seems appropriate to assume independence between pots, i.e., independence between the paired random vectors. So we assume that X_1, \dots, X_{15} form a random sample. As a tentative model, consider the location model

$$X_i = \mu + e_i, \quad i = 1, \dots, 15,$$

where the random variables e_i are iid with continuous density $f(x)$. For this model, there is no loss in generality in assuming that the mean of e_i is 0, for, otherwise, we can simply redefine μ . Hence, $E(X_i) = \mu$. Further, the density of X_i is $f_X(x; \mu) = f(x - \mu)$. In practice, the goodness of the model is always a concern and diagnostics based on the data would be run to confirm the quality of the model.

If $\mu = E(X_i) = 0$, then $E(Y_i) = E(Z_i)$; i.e., on average, the cross-fertilized plants grow to the same height as the self-fertilized plants. While, if $\mu > 0$ then

Table 4.5.1: 2×2 Decision Table for a Hypothesis Test

	True State of Nature	
Decision	H_0 is True	H_1 is True
Reject H_0	Type I Error	Correct Decision
Accept H_0	Correct Decision	Type II Error

$E(Y_i) > E(Z_i)$; i.e., on average the cross-fertilized plants are taller than the self-fertilized plants. Under this model, our hypotheses are

$$H_0 : \mu = 0 \text{ versus } H_1 : \mu > 0. \quad (4.5.2)$$

Hence, $\omega_0 = \{0\}$ represents no difference in the treatments, while $\omega_1 = (0, \infty)$ represents that the mean height of cross-fertilized *Zea mays* exceeds the mean height of self-fertilized *Zea mays*. ■

To complete the testing structure for the general problem described at the beginning of this section, we need to discuss decision rules. Recall that X_1, \dots, X_n is a random sample from the distribution of a random variable X that has density $f(x; \theta)$, where $\theta \in \Omega$. Consider testing the hypotheses $H_0 : \theta \in \omega_0$ versus $H_1 : \theta \in \omega_1$, where $\omega_0 \cup \omega_1 = \Omega$. Denote the space of the sample by \mathcal{D} ; that is, $\mathcal{D} = \text{space}\{(X_1, \dots, X_n)\}$. A **test** of H_0 versus H_1 is based on a subset C of \mathcal{D} . This set C is called the **critical region** and its corresponding decision rule (test) is

$$\begin{aligned} \text{Reject } H_0 \text{ (Accept } H_1) &\quad \text{if } (X_1, \dots, X_n) \in C \\ \text{Retain } H_0 \text{ (Reject } H_1) &\quad \text{if } (X_1, \dots, X_n) \in C^c. \end{aligned} \quad (4.5.3)$$

For a given critical region, the 2×2 decision table as shown in Table 4.5.1, summarizes the results of the hypothesis test in terms of the true state of nature. Besides the correct decisions, two errors can occur. A **Type I** error occurs if H_0 is rejected when it is true, while a **Type II** error occurs if H_0 is accepted when H_1 is true.

The goal, of course, is to select a critical region from all possible critical regions which minimizes the probabilities of these errors. In general, this is not possible. The probabilities of these errors often have a seesaw effect. This can be seen immediately in an extreme case. Simply let $C = \emptyset$. With this critical region, we would never reject H_0 , so the probability of Type I error would be 0, but the probability of Type II error is 1. Often we consider Type I error to be the worse of the two errors. We then proceed by selecting critical regions that bound the probability of Type I error and then among these critical regions we try to select one that minimizes the probability of Type II error.

Definition 4.5.1. We say a critical region C is of **size α** if

$$\alpha = \max_{\theta \in \omega_0} P_\theta[(X_1, \dots, X_n) \in C]. \quad (4.5.4)$$

Over all critical regions of size α , we want to consider critical regions that have lower probabilities of Type II error. We also can look at the complement of a Type II error, namely, rejecting H_0 when H_1 is true, which is a correct decision, as marked in Table 4.5.1. Since we desire to maximize the probability of this latter decision, we want the probability of it to be as large as possible. That is, for $\theta \in \omega_1$, we want to maximize

$$1 - P_\theta[\text{Type II Error}] = P_\theta[(X_1, \dots, X_n) \in C].$$

The probability on the right side of this equation is called the **power** of the test at θ . It is the probability that the test detects the alternative θ when $\theta \in \omega_1$ is the true parameter. So minimizing the probability of Type II error is equivalent to maximizing power.

We define the **power function** of a critical region to be

$$\gamma_C(\theta) = P_\theta[(X_1, \dots, X_n) \in C]; \quad \theta \in \omega_1. \quad (4.5.5)$$

Hence, given two critical regions C_1 and C_2 , which are both of size α , C_1 is better than C_2 if $\gamma_{C_1}(\theta) \geq \gamma_{C_2}(\theta)$ for all $\theta \in \omega_1$. In Chapter 8, we obtain optimal critical regions for specific situations. In this section, we want to illustrate these concepts of hypothesis testing with several examples.

Example 4.5.2 (Test for a Binomial Proportion of Success). Let X be a Bernoulli random variable with probability of success p . Suppose we want to test, at size α ,

$$H_0 : p = p_0 \text{ versus } H_1 : p < p_0, \quad (4.5.6)$$

where p_0 is specified. As an illustration, suppose “success” is dying from a certain disease and p_0 is the probability of dying with some standard treatment. A new treatment is used on several (randomly chosen) patients, and it is hoped that the probability of dying under this new treatment is less than p_0 . Let X_1, \dots, X_n be a random sample from the distribution of X and let $S = \sum_{i=1}^n X_i$ be the total number of successes in the sample. An intuitive decision rule (critical region) is

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } S \leq k, \quad (4.5.7)$$

where k is such that $\alpha = P_{H_0}[S \leq k]$. Since S has a $b(n, p_0)$ distribution under H_0 , k is determined by $\alpha = P_{p_0}[S \leq k]$. Because the binomial distribution is discrete, however, it is likely that there is no integer k that solves this equation. For example, suppose $n = 20$, $p_0 = 0.7$, and $\alpha = 0.15$. Then under H_0 , S has a binomial $b(20, 0.7)$ distribution. Hence, computationally, $P_{H_0}[S \leq 11] = \text{pbinom}(11, 20, 0.7) = 0.1133$ and $P_{H_0}[S \leq 12] = \text{pbinom}(12, 20, 0.7) = 0.2277$. Hence, erring on the conservative side, we would probably choose k to be 11 and $\alpha = 0.1133$. As n increases, this is less of a problem; see, also, the later discussion on p -values. In general, the power of the test for the hypotheses (4.5.6) is

$$\gamma(p) = P_p[S \leq k], \quad p < p_0. \quad (4.5.8)$$

The curve labeled Test 1 in Figure 4.5.1 is the power function for the case $n = 20$, $p_0 = 0.7$, and $\alpha = 0.1133$. Notice that the power function is decreasing. The

power is higher to detect the alternative $p = 0.2$ than $p = 0.6$. In Section 8.2, we prove in general the monotonicity of the power function for binomial tests of these hypotheses. Using this monotonicity, we extend our test to the more general null hypothesis $H_0 : p \geq p_0$ rather than simply $H_0 : p = p_0$. Using the same decision rule as we used for the hypotheses (4.5.6), the definition of the size of a test (4.5.4), and the monotonicity of the power curve, we have

$$\max_{p \geq p_0} P_p[S \leq k] = P_{p_0}[S \leq k] = \alpha,$$

i.e., the same size as for the original null hypothesis.

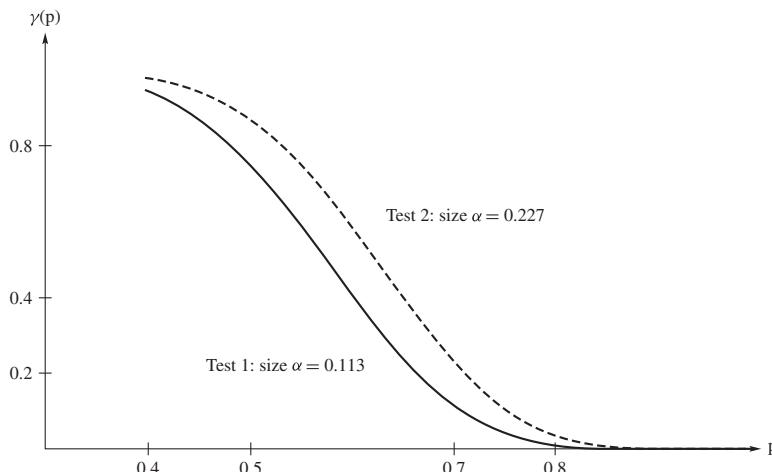

Figure 4.5.1: Power curves for tests 1 and 2; see Example 4.5.2.

Denote by Test 1 the test for the situation with $n = 20$, $p_0 = 0.70$, and size $\alpha = 0.1133$. Suppose we have a second test (Test 2) with an increased size. How does the power function of Test 2 compare to Test 1? As an example, suppose for Test 2, we select $\alpha = 0.2277$. Hence, for Test 2, we reject H_0 if $S \leq 12$. Figure 4.5.1 displays the resulting power function. Note that while Test 2 has a higher probability of committing a Type I error, it also has a higher power at each alternative $p < 0.7$. Exercise 4.5.7 shows that this is true for these binomial tests. It is true in general; that is, if the size of the test increases, power does too. For this example, the R function `binpower.r`, found at the site listed in the Preface, produces a version of Figure 4.5.1. ■

Remark 4.5.1 (Nomenclature). Since in Example 4.5.2, the first null hypothesis $H_0 : p = p_0$ completely specifies the underlying distribution, it is called a **simple** hypothesis. Most hypotheses, such as $H_1 : p < p_0$, are **composite** hypotheses, because they are composed of many simple hypotheses and, hence, do not completely specify the distribution.

As we study more and more statistics, we discover that often other names are used for the size, α , of the critical region. Frequently, α is also called the **signifi-**

cance level of the test associated with that critical region. Moreover, sometimes α is called the “maximum of probabilities of committing an error of Type I” and the “maximum of the power of the test when H_0 is true.” It is disconcerting to the student to discover that there are so many names for the same thing. However, all of them are used in the statistical literature, and we feel obligated to point out this fact. ■

The test in the last example is based on the exact distribution of its test statistic, i.e., the binomial distribution. Often we cannot obtain the distribution of the test statistic in closed form. As with approximate confidence intervals, however, we can frequently appeal to the Central Limit Theorem to obtain an approximate test; see Theorem 4.2.1. Such is the case for the next example.

Example 4.5.3 (Large Sample Test for the Mean). Let X be a random variable with mean μ and finite variance σ^2 . We want to test the hypotheses

$$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu > \mu_0, \quad (4.5.9)$$

where μ_0 is specified. To illustrate, suppose μ_0 is the mean level on a standardized test of students who have been taught a course by a standard method of teaching. Suppose it is hoped that a new method that incorporates computers has a mean level $\mu > \mu_0$, where $\mu = E(X)$ and X is the score of a student taught by the new method. This conjecture is tested by having n students (randomly selected) taught under this new method.

Let X_1, \dots, X_n be a random sample from the distribution of X and denote the sample mean and variance by \bar{X} and S^2 , respectively. Because \bar{X} is an unbiased estimate of μ , an intuitive decision rule is given by

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \bar{X} \text{ is much larger than } \mu_0. \quad (4.5.10)$$

In general, the distribution of the sample mean cannot be obtained in closed form. In Example 4.5.4, under the strong assumption of normality for the distribution of X , we obtain an exact test. For now, the Central Limit Theorem (Theorem 4.2.1) shows that the distribution of $(\bar{X} - \mu)/(S/\sqrt{n})$ is approximately $N(0, 1)$. Using this, we obtain a test with an approximate size α , with the decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \geq z_\alpha. \quad (4.5.11)$$

The test is intuitive. To reject H_0 , \bar{X} must exceed μ_0 by at least $z_\alpha S/\sqrt{n}$. To approximate the power function of the test, we use the Central Limit Theorem. Upon substituting σ for S , it readily follows that the approximate power function is

$$\begin{aligned} \gamma(\mu) &= P_\mu(\bar{X} \geq \mu_0 + z_\alpha \sigma / \sqrt{n}) \\ &= P_\mu \left(\frac{\bar{X} - \mu}{\sigma / \sqrt{n}} \geq \frac{\mu_0 - \mu}{\sigma / \sqrt{n}} + z_\alpha \right) \\ &\approx 1 - \Phi \left(z_\alpha + \frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} \right) \\ &= \Phi \left(-z_\alpha - \frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} \right). \end{aligned} \quad (4.5.12)$$

So if we have some reasonable idea of what σ equals, we can compute the approximate power function. As Exercise 4.5.1 shows, this approximate power function is strictly increasing in μ , so as in the last example, we can change the null hypotheses to

$$H_0 : \mu \leq \mu_0 \text{ versus } H_1 : \mu > \mu_0. \quad (4.5.13)$$

Our asymptotic test has approximate size α for these hypotheses. ■

Example 4.5.4 (Test for μ Under Normality). Let X have a $N(\mu, \sigma^2)$ distribution. As in Example 4.5.3, consider the hypotheses

$$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu > \mu_0, \quad (4.5.14)$$

where μ_0 is specified. Assume that the desired size of the test is α , for $0 < \alpha < 1$. Suppose X_1, \dots, X_n is a random sample from a $N(\mu, \sigma^2)$ distribution. Let \bar{X} and S^2 denote the sample mean and variance, respectively. Our intuitive rejection rule is to reject H_0 in favor of H_1 if \bar{X} is much larger than μ_0 . Unlike Example 4.5.3, we now know the distribution of the statistic \bar{X} . In particular, by Part (d) of Theorem 3.6.1, under H_0 the statistic $T = (\bar{X} - \mu_0)/(S/\sqrt{n})$ has a t -distribution with $n - 1$ degrees of freedom. Using the distribution of T , it follows that this rejection rule has exact level α :

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \geq t_{\alpha, n-1}, \quad (4.5.15)$$

where $t_{\alpha, n-1}$ is the upper α critical point of a t -distribution with $n - 1$ degrees of freedom; i.e., $\alpha = P(T > t_{\alpha, n-1})$. This is often called the **t -test** of $H_0 : \mu = \mu_0$.

Note the differences between this rejection rule and the large sample rule, (4.5.11). The large sample rule has approximate level α , while this has exact level α . Of course, we now have to assume that X has a normal distribution. In practice, we may not be willing to assume that the population is normal. Usually t -critical values are larger than z -critical values; hence, the t -test is conservative relative to the large sample test. So, in practice, many statisticians often use the t -test.

The R code `t.test(x, mu=mu0, alt="greater")` computes the t -test for the hypotheses (4.5.14), where the R vector `x` contains the sample. ■

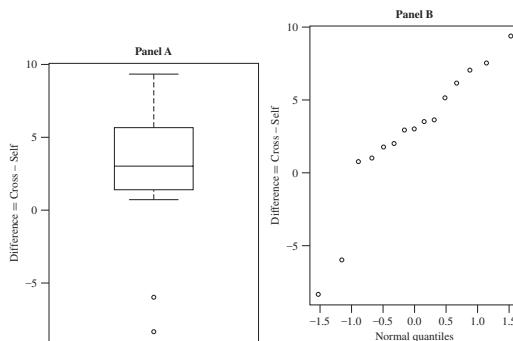

Example 4.5.5 (Example 4.5.1, Continued). The data for Darwin's experiment on *Zea mays* are recorded in Table 4.5.2 and are, also, in the file `darwin.rda`. A boxplot and a normal $q-q$ plot of the 15 differences, $x_i = y_i - z_i$, are found in Figure 4.5.2. Based on these plots, we can see that there seem to be two outliers, Pots 2 and 15. In these two pots, the self-fertilized *Zea mays* are much taller than their cross-fertilized pairs. Except for these two outliers, the differences, $y_i - z_i$, are positive, indicating that the cross-fertilization leads to taller plants. We proceed to conduct a test of hypotheses (4.5.2), as discussed in Example 4.5.4. We use the decision rule given by (4.5.15) with $\alpha = 0.05$. As Exercise 4.5.2 shows, the values of the sample mean and standard deviation for the differences, x_i , are $\bar{x} = 2.62$ and $s_x = 4.72$. Hence the t -test statistic is 2.15, which exceeds the t -critical value, $t_{0.05, 14} = qt(0.95, 14) = 1.76$. Thus we reject H_0 and conclude that cross-fertilized *Zea mays* are on the average taller than self-fertilized *Zea mays*. Because of the

Table 4.5.2: Plant Growth

Pot	1	2	3	4	5	6	7	8
Cross	23.500	12.000	21.000	22.000	19.125	21.500	22.125	20.375
Self	17.375	20.375	20.000	20.000	18.375	18.625	18.625	15.250
Pot	9	10	11	12	13	14	15	
Cross	18.250	21.625	23.250	21.000	22.125	23.000	12.000	
Self	16.500	18.000	16.250	18.000	12.750	15.500	18.000	

outliers, normality of the error distribution is somewhat dubious, and we use the test in a conservative manner, as discussed at the end of Example 4.5.4.

Assuming that the rda file `darwin.rda` has been loaded in R, the code for the above t -test is `t.test(cross-self, mu=0, alt="greater")` which evaluates the t -test statistic to be 2.1506. ■

**Figure 4.5.2:** Boxplot and normal $q-q$ plot for the data of Example 4.5.5.

EXERCISES

In many of these exercises, use R or another statistical package for computations and graphs of power functions.

- 4.5.1.** Show that the approximate power function given in expression (4.5.12) of Example 4.5.3 is a strictly increasing function of μ . Show then that the test discussed in this example has approximate size α for testing

$$H_0 : \mu \leq \mu_0 \text{ versus } H_1 : \mu > \mu_0.$$

- 4.5.2.** For the Darwin data tabled in Example 4.5.5, verify that the Student t -test statistic is 2.15.

- 4.5.3.** Let X have a pdf of the form $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, zero elsewhere, where $\theta \in \{\theta : \theta = 1, 2\}$. To test the simple hypothesis $H_0 : \theta = 1$ against the alternative simple hypothesis $H_1 : \theta = 2$, use a random sample X_1, X_2 of size $n = 2$

and define the critical region to be $C = \{(x_1, x_2) : \frac{3}{4} \leq x_1 x_2\}$. Find the power function of the test.

4.5.4. Let X have a binomial distribution with the number of trials $n = 10$ and with p either $1/4$ or $1/2$. The simple hypothesis $H_0 : p = \frac{1}{2}$ is rejected, and the alternative simple hypothesis $H_1 : p = \frac{1}{4}$ is accepted, if the observed value of X_1 , a random sample of size 1, is less than or equal to 3. Find the significance level and the power of the test.

4.5.5. Let X_1, X_2 be a random sample of size $n = 2$ from the distribution having pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, zero elsewhere. We reject $H_0 : \theta = 2$ and accept $H_1 : \theta = 1$ if the observed values of X_1, X_2 , say x_1, x_2 , are such that

$$\frac{f(x_1; 2)f(x_2; 2)}{f(x_1; 1)f(x_2; 1)} \leq \frac{1}{2}.$$

Here $\Omega = \{\theta : \theta = 1, 2\}$. Find the significance level of the test and the power of the test when H_0 is false.

4.5.6. Consider the tests Test 1 and Test 2 for the situation discussed in Example 4.5.2. Consider the test that rejects H_0 if $S \leq 10$. Find the level of significance for this test and sketch its power curve as in Figure 4.5.1.

4.5.7. Consider the situation described in Example 4.5.2. Suppose we have two tests A and B defined as follows. For Test A, H_0 is rejected if $S \leq k_A$, while for Test B, H_0 is rejected if $S \leq k_B$. If Test A has a higher level of significance than Test B, show that Test A has higher power than Test B at each alternative.

4.5.8. Let us say the life of a tire in miles, say X , is normally distributed with mean θ and standard deviation 5000. Past experience indicates that $\theta = 30,000$. The manufacturer claims that the tires made by a new process have mean $\theta > 30,000$. It is possible that $\theta = 35,000$. Check his claim by testing $H_0 : \theta = 30,000$ against $H_1 : \theta > 30,000$. We observe n independent values of X , say x_1, \dots, x_n , and we reject H_0 (thus accept H_1) if and only if $\bar{x} \geq c$. Determine n and c so that the power function $\gamma(\theta)$ of the test has the values $\gamma(30,000) = 0.01$ and $\gamma(35,000) = 0.98$.

4.5.9. Let X have a Poisson distribution with mean θ . Consider the simple hypothesis $H_0 : \theta = \frac{1}{2}$ and the alternative composite hypothesis $H_1 : \theta < \frac{1}{2}$. Thus $\Omega = \{\theta : 0 < \theta \leq \frac{1}{2}\}$. Let X_1, \dots, X_{12} denote a random sample of size 12 from this distribution. We reject H_0 if and only if the observed value of $Y = X_1 + \dots + X_{12} \leq 2$. Show that the following R code graphs the power function of this test:

```
theta=seq(.1,.5,.05); gam=ppois(2,theta*12)
plot(gam~theta,pch=" ",xlab=expression(theta),ylab=expression(gamma))
lines(gam~theta)
```

Run the code. Determine the significance level from the plot.

4.5.10. Let Y have a binomial distribution with parameters n and p . We reject $H_0 : p = \frac{1}{2}$ and accept $H_1 : p > \frac{1}{2}$ if $Y \geq c$. Find n and c to give a power function $\gamma(p)$ which is such that $\gamma(\frac{1}{2}) = 0.10$ and $\gamma(\frac{2}{3}) = 0.95$, approximately.

4.5.11. Let $Y_1 < Y_2 < Y_3 < Y_4$ be the order statistics of a random sample of size $n = 4$ from a distribution with pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere, where $0 < \theta$. The hypothesis $H_0 : \theta = 1$ is rejected and $H_1 : \theta > 1$ is accepted if the observed $Y_4 \geq c$.

- (a) Find the constant c so that the significance level is $\alpha = 0.05$.
- (b) Determine the power function of the test.

4.5.12. Let X_1, X_2, \dots, X_8 be a random sample of size $n = 8$ from a Poisson distribution with mean μ . Reject the simple null hypothesis $H_0 : \mu = 0.5$ and accept $H_1 : \mu > 0.5$ if the observed sum $\sum_{i=1}^8 x_i \geq 8$.

- (a) Show that the significance level is `1-ppois(7,8*.5)`.
- (b) Use R to determine $\gamma(0.75)$, $\gamma(1)$, and $\gamma(1.25)$.
- (c) Modify the code in Exercise 4.5.9 to obtain a plot of the power function.

4.5.13. Let p denote the probability that, for a particular tennis player, the first serve is good. Since $p = 0.40$, this player decided to take lessons in order to increase p . When the lessons are completed, the hypothesis $H_0 : p = 0.40$ is tested against $H_1 : p > 0.40$ based on $n = 25$ trials. Let Y equal the number of first serves that are good, and let the critical region be defined by $C = \{Y : Y \geq 13\}$.

- (a) Show that α is computed by $\alpha = 1-pbinom(12, 25, .4)$.
- (b) Find $\beta = P(Y < 13)$ when $p = 0.60$; that is, $\beta = P(Y \leq 12; p = 0.60)$ so that $1 - \beta$ is the power at $p = 0.60$.

4.5.14. Let S denote the number of success in $n = 40$ Bernoulli trials with probability of success p . Consider the hypotheses: $H_0 : p \leq 0.3$ versus $H_1 : p > 0.3$. Consider the two tests: (1) Reject H_0 if $S \geq 16$ and (2) Reject H_0 if $S \geq 17$. Determine the level of these tests. The R function `binpower.r` produces a version of Figure 4.5.1. For this exercise, write a similar R function that graphs the power functions of the above two tests.

4.6 Additional Comments About Statistical Tests

All of the alternative hypotheses considered in Section 4.5 were **one-sided hypotheses**. For illustration, in Exercise 4.5.8 we tested $H_0 : \mu = 30,000$ against the one-sided alternative $H_1 : \mu > 30,000$, where μ is the mean of a normal distribution having standard deviation $\sigma = 5000$. Perhaps in this situation, though, we think the manufacturer's process has changed but are unsure of the direction. That is, we are interested in the alternative $H_1 : \mu \neq 30,000$. In this section, we further explore hypotheses testing and we begin with the construction of a test for a two-sided alternative.

Example 4.6.1 (Large Sample Two-Sided Test for the Mean). In order to see how to construct a test for a two-sided alternative, reconsider Example 4.5.3, where we constructed a large sample one-sided test for the mean of a random variable. As in Example 4.5.3, let X be a random variable with mean μ and finite variance σ^2 . Here, though, we want to test

$$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu \neq \mu_0, \quad (4.6.1)$$

where μ_0 is specified. Let X_1, \dots, X_n be a random sample from the distribution of X and denote the sample mean and variance by \bar{X} and S^2 , respectively. For the one-sided test, we rejected H_0 if \bar{X} was too large; hence, for the hypotheses (4.6.1), we use the decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \bar{X} \leq h \text{ or } \bar{X} \geq k, \quad (4.6.2)$$

where h and k are such that $\alpha = P_{H_0}[\bar{X} \leq h \text{ or } \bar{X} \geq k]$. Clearly, $h < k$; hence, we have

$$\alpha = P_{H_0}[\bar{X} \leq h \text{ or } \bar{X} \geq k] = P_{H_0}[\bar{X} \leq h] + P_{H_0}[\bar{X} \geq k].$$

Since, at least for large samples, the distribution of \bar{X} is symmetrically distributed about μ_0 , under H_0 , an intuitive rule is to divide α equally between the two terms on the right side of the above expression; that is, h and k are chosen by

$$P_{H_0}[\bar{X} \leq h] = \alpha/2 \text{ and } P_{H_0}[\bar{X} \geq k] = \alpha/2. \quad (4.6.3)$$

From Theorem 4.2.1, it follows that $(\bar{X} - \mu_0)/(S/\sqrt{n})$ is approximately $N(0, 1)$. This and (4.6.3) lead to the approximate decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \left| \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \right| \geq z_{\alpha/2}. \quad (4.6.4)$$

Upon substituting σ for S , it readily follows that the approximate power function is

$$\begin{aligned} \gamma(\mu) &= P_\mu(\bar{X} \leq \mu_0 - z_{\alpha/2}\sigma/\sqrt{n}) + P_\mu(\bar{X} \geq \mu_0 + z_{\alpha/2}\sigma/\sqrt{n}) \\ &= \Phi\left(\frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} - z_{\alpha/2}\right) + 1 - \Phi\left(\frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} + z_{\alpha/2}\right), \end{aligned} \quad (4.6.5)$$

where $\Phi(z)$ is the cdf of a standard normal random variable; see (3.4.9). So if we have some reasonable idea of what σ equals, we can compute the approximate power function. Note that the derivative of the power function is

$$\gamma'(\mu) = \frac{\sqrt{n}}{\sigma} \left[\phi\left(\frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} + z_{\alpha/2}\right) - \phi\left(\frac{\sqrt{n}(\mu_0 - \mu)}{\sigma} - z_{\alpha/2}\right) \right], \quad (4.6.6)$$

where $\phi(z)$ is the pdf of a standard normal random variable. Then we can show that $\gamma(\mu)$ has a critical value at μ_0 which is the minimum; see Exercise 4.6.2. Further, $\gamma(\mu)$ is strictly decreasing for $\mu < \mu_0$ and strictly increasing for $\mu > \mu_0$. ■

Consider again the situation at the beginning of this section. Suppose we want to test

$$H_0 : \mu = 30,000 \text{ versus } H_1 : \mu \neq 30,000. \quad (4.6.7)$$

Suppose $n = 20$ and $\alpha = 0.01$. Then the rejection rule (4.6.4) becomes

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \left| \frac{\bar{X} - 30,000}{S/\sqrt{20}} \right| \geq 2.575. \quad (4.6.8)$$

Figure 4.6.1 displays the power curve for this test when $\sigma = 5000$ is substituted in for S . For comparison, the power curve for the test with level $\alpha = 0.05$ is also shown. The R function `zpower` computes a version of this figure.

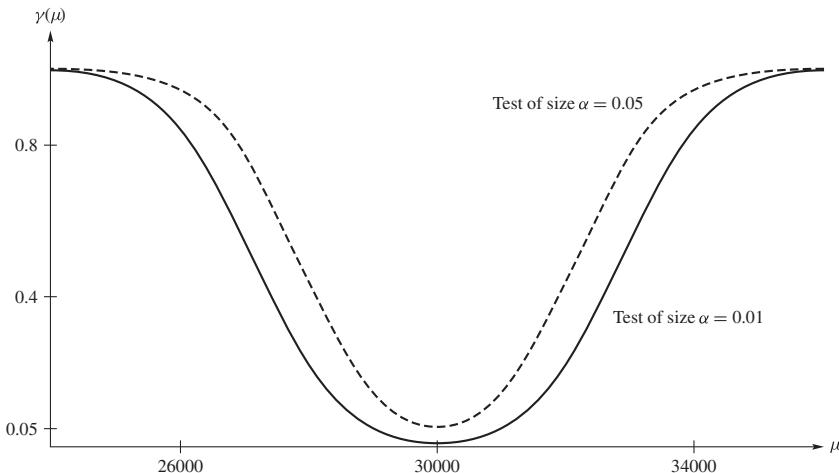

Figure 4.6.1: Power curves for the tests of the hypotheses (4.6.7).

This two-sided test for the mean is approximate. If we assume that X has a normal distribution, then, as Exercise 4.6.3 shows, the following test has exact size α for testing $H_0 : \mu = \mu_0$ versus $H_1 : \mu \neq \mu_0$:

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \left| \frac{\bar{X} - \mu_0}{S/\sqrt{n}} \right| \geq t_{\alpha/2, n-1}. \quad (4.6.9)$$

It too has a bowl-shaped power curve similar to Figure 4.6.1, although it is not as easy to show; see Lehmann (1986).

For computation in R, the code `t.test(x, mu=mu0)` obtains the two-sided t -test of hypotheses (4.6.1), when the R vector `x` contains the sample.

There exists a relationship between two-sided tests and confidence intervals. Consider the two-sided t -test (4.6.9). Here, we use the rejection rule with “if and only if” replacing “if.” Hence, in terms of acceptance, we have

$$\text{Accept } H_0 \text{ if and only if } \mu_0 - t_{\alpha/2, n-1} S/\sqrt{n} < \bar{X} < \mu_0 + t_{\alpha/2, n-1} S/\sqrt{n}.$$

But this is easily shown to be

$$\text{Accept } H_0 \text{ if and only if } \mu_0 \in (\bar{X} - t_{\alpha/2, n-1} S/\sqrt{n}, \bar{X} + t_{\alpha/2, n-1} S/\sqrt{n}); \quad (4.6.10)$$

that is, we accept H_0 at significance level α if and only if μ_0 is in the $(1 - \alpha)100\%$ confidence interval for μ . Equivalently, we reject H_0 at significance level α if and only if μ_0 is not in the $(1 - \alpha)100\%$ confidence interval for μ . This is true for all the two-sided tests and hypotheses discussed in this text. There is also a similar relationship between one-sided tests and one-sided confidence intervals.

Once we recognize this relationship between confidence intervals and tests of hypothesis, we can use all those statistics that we used to construct confidence intervals to test hypotheses, not only against two-sided alternatives but one-sided ones as well. Without listing all of these in a table, we present enough of them so that the principle can be understood.

Example 4.6.2. Let independent random samples be taken from $N(\mu_1, \sigma^2)$ and $N(\mu_2, \sigma^2)$, respectively. Say these have the respective sample characteristics n_1 , \bar{X} , S_1^2 and n_2 , \bar{Y} , S_2^2 . Let $n = n_1 + n_2$ denote the combined sample size and let $S_p^2 = [(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2]/(n - 2)$, (4.2.11), be the pooled estimator of the common variance. At $\alpha = 0.05$, reject $H_0 : \mu_1 = \mu_2$ and accept the one-sided alternative $H_1 : \mu_1 > \mu_2$ if

$$T = \frac{\bar{X} - \bar{Y} - 0}{S_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \geq t_{.05, n-2},$$

because, under $H_0 : \mu_1 = \mu_2$, T has a $t(n - 2)$ -distribution. A rigorous development of this test is given in Example 8.3.1. ■

Example 4.6.3. Say X is $b(1, p)$. Consider testing $H_0 : p = p_0$ against $H_1 : p < p_0$. Let X_1, \dots, X_n be a random sample from the distribution of X and let $\hat{p} = \bar{X}$. To test H_0 versus H_1 , we use either

$$Z_1 = \frac{\hat{p} - p_0}{\sqrt{p_0(1 - p_0)/n}} \leq c \quad \text{or} \quad Z_2 = \frac{\hat{p} - p_0}{\sqrt{\hat{p}(1 - \hat{p})/n}} \leq c.$$

If n is large, both Z_1 and Z_2 have approximate standard normal distributions provided that $H_0 : p = p_0$ is true. Hence, if c is set at -1.645 , then the approximate significance level is $\alpha = 0.05$. Some statisticians use Z_1 and others Z_2 . We do not have strong preferences one way or the other because the two methods provide about the same numerical results. As one might suspect, using Z_1 provides better probabilities for power calculations if the true p is close to p_0 , while Z_2 is better if H_0 is clearly false. However, with a two-sided alternative hypothesis, Z_2 does provide a better relationship with the confidence interval for p . That is, $|Z_2| < z_{\alpha/2}$ is equivalent to p_0 being in the interval from

$$\hat{p} - z_{\alpha/2} \sqrt{\frac{\hat{p}(1 - \hat{p})}{n}} \quad \text{to} \quad \hat{p} + z_{\alpha/2} \sqrt{\frac{\hat{p}(1 - \hat{p})}{n}},$$

which is the interval that provides a $(1 - \alpha)100\%$ approximate confidence interval for p as considered in Section 4.2. ■

In closing this section, we introduce the concept of **randomized tests**.

Example 4.6.4. Let X_1, X_2, \dots, X_{10} be a random sample of size $n = 10$ from a Poisson distribution with mean θ . A critical region for testing $H_0 : \theta = 0.1$ against $H_1 : \theta > 0.1$ is given by $Y = \sum_1^{10} X_i \geq 3$. The statistic Y has a Poisson distribution with mean 10θ . Thus, with $\theta = 0.1$ so that the mean of Y is 1, the significance level of the test is

$$P(Y \geq 3) = 1 - P(Y \leq 2) = 1 - \text{ppois}(2, 1) = 1 - 0.920 = 0.080.$$

If, on the other hand, the critical region defined by $\sum_1^{10} x_i \geq 4$ is used, the significance level is

$$\alpha = P(Y \geq 4) = 1 - P(Y \leq 3) = 1 - \text{ppois}(3, 1) = 1 - 0.981 = 0.019.$$

For instance, if a significance level of about $\alpha = 0.05$, say, is desired, most statisticians would use one of these tests; that is, they would adjust the significance level to that of one of these convenient tests. However, a significance level of $\alpha = 0.05$ can be achieved in the following way. Let W have a Bernoulli distribution with probability of success equal to

$$P(W = 1) = \frac{0.050 - 0.019}{0.080 - 0.019} = \frac{31}{61}.$$

Assume that W is selected independently of the sample. Consider the rejection rule

$$\text{Reject } H_0 \text{ if } \sum_1^{10} x_i \geq 4 \text{ or if } \sum_1^{10} x_i = 3 \text{ and } W = 1.$$

The significance level of this rule is

$$\begin{aligned} P_{H_0}(Y \geq 4) + P_{H_0}(\{Y = 3\} \cap \{W = 1\}) &= P_{H_0}(Y \geq 4) \\ &\quad + P_{H_0}(Y = 3)P(W = 1) \\ &= 0.019 + 0.061 \frac{31}{61} = 0.05; \end{aligned}$$

hence, the decision rule has exactly level 0.05. The process of performing the auxiliary experiment to decide whether to reject or not when $Y = 3$ is sometimes referred to as a **randomized test**. ■

4.6.1 Observed Significance Level, p -value

Not many statisticians like randomized tests in practice, because the use of them means that two statisticians could make the same assumptions, observe the same data, apply the same test, and yet make different decisions. Hence, they usually adjust their significance level so as not to randomize. As a matter of fact, many statisticians report what are commonly called **observed significance levels** or **p -values** (for *probability values*).

A general example suffices to explain observed significance levels. Let X_1, \dots, X_n be a random sample from a $N(\mu, \sigma^2)$ distribution, where both μ and σ^2 are unknown.

Consider, first, the one-sided hypotheses $H_0 : \mu = \mu_0$ versus $H_1 : \mu > \mu_0$, where μ_0 is specified. Write the rejection rule as

$$\text{Reject } H_0 \text{ in favor of } H_1, \text{ if } \bar{X} \geq k, \quad (4.6.11)$$

where \bar{X} is the sample mean. Previously we have specified a level and then solved for k . In practice, though, the level is not specified. Instead, once the sample is observed, the realized value \bar{x} of \bar{X} is computed and we ask the question: Is \bar{x} sufficiently large to reject H_0 in favor of H_1 ? To answer this we calculate the p -value which is the probability,

$$p\text{-value} = P_{H_0}(\bar{X} \geq \bar{x}). \quad (4.6.12)$$

Note that this is a data-based “significance level” and we call it the **observed significance level** or the p -value. The hypothesis H_0 is rejected at all levels greater than or equal to the p -value. For example, if the p -value is 0.048, and the nominal α level is 0.05 then H_0 would be rejected; however, if the nominal α level is 0.01, then H_0 would not be rejected. In summary, the experimenter sets the hypotheses; the statistician selects the test statistic and rejection rule; the data are observed and the statistician reports the p -value to the experimenter; and the experimenter decides whether the p -value is sufficiently small to warrant rejection of H_0 in favor of H_1 . The following example provides a numerical illustration.

Example 4.6.5. Recall the Darwin data discussed in Example 4.5.5. It was a paired design on the heights of cross and self-fertilized *Zea mays* plants. In each of 15 pots, one cross-fertilized and one self-fertilized were grown. The data of interest are the 15 paired differences, (cross – self). As in Example 4.5.5, let X_i denote the paired difference for the i th pot. Let μ be the true mean difference. The hypotheses of interest are $H_0 : \mu = 0$ versus $H_1 : \mu > 0$. The standardized rejection rule is

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } T \geq k,$$

where $T = \bar{X}/(S/\sqrt{15})$, where \bar{X} and S are respectively the sample mean and standard deviation of the differences. The alternative hypothesis states that on the average cross-fertilized plants are taller than self-fertilized plants. From Example 4.5.5 the t -test statistic has the value 2.15. Letting $t(14)$ denote a random variable with the t -distribution with 14 degrees of freedom, and using R the p -value for the experiment is

$$P[t(14) > 2.15] = 1 - pt(2.15, 14) = 1 - 0.9752 = 0.0248. \quad (4.6.13)$$

In practice, with this p -value, H_0 would be rejected at all levels greater than or equal to 0.0248. This observed significance level is also part of the output from the R call `t.test(cross-self, mu=0, alt="greater")`. ■

Returning to the discussion above, suppose the hypotheses are $H_0 : \mu = \mu_0$ versus $H_1 : \mu < \mu_0$. Obviously, the observed significance level in this case is $p\text{-value} = P_{H_0}(\bar{X} \leq \bar{x})$. For the two-sided hypotheses $H_0 : \mu = \mu_0$ versus $H_1 : \mu \neq \mu_0$, our “unspecified” rejection rule is

$$\text{Reject } H_0 \text{ in favor of } H_1, \text{ if } \bar{X} \leq l \text{ or } \bar{X} \geq k. \quad (4.6.14)$$

For the p -value, compute each of the one-sided p -values, take the smaller p -value, and double it. For an illustration, in the Darwin example, suppose the the hypotheses are $H_0 : \mu = 0$ versus $H_1 : \mu \neq 0$. Then the p -value is $2(0.0248) = 0.0496$. As a final note on p -values for two-sided hypotheses, suppose the test statistic can be expressed in terms of a t -test statistic. In this case the p -value can be found equivalently as follows. If d is the realized value of the t -test statistic then the p -value is

$$p\text{-value} = P_{H_0}[|t| \geq |d|], \quad (4.6.15)$$

where, under H_0 , t has a t -distribution with $n - 1$ degrees of freedom.

In this discussion on p -values, keep in mind that good science dictates that the hypotheses should be known before the data are drawn.

EXERCISES

4.6.1. The R function `zpower`, found at the site listed in the Preface, computes the plot in Figure 4.6.1. Consider the two-sided test for proportions discussed in Example 4.6.3 based on the test statistic Z_1 . Specifically consider the hypotheses $H_0 : p = .6$ versus $H_1 : p \neq .6$. Using the sample size $n = 50$ and the level $\alpha = 0.05$, write a R program, similar to `zpower`, which computes a plot of the power curve for this test on a proportion.

4.6.2. Consider the power function $\gamma(\mu)$ and its derivative $\gamma'(\mu)$ given by (4.6.5) and (4.6.6). Show that $\gamma'(\mu)$ is strictly negative for $\mu < \mu_0$ and strictly positive for $\mu > \mu_0$.

4.6.3. Show that the test defined by 4.6.9 has exact size α for testing $H_0 : \mu = \mu_0$ versus $H_1 : \mu \neq \mu_0$.

4.6.4. Consider the one-sided t -test for $H_0 : \mu = \mu_0$ versus $H_{A1} : \mu > \mu_0$ constructed in Example 4.5.4 and the two-sided t -test for t -test for $H_0 : \mu = \mu_0$ versus $H_1 : \mu \neq \mu_0$ given in (4.6.9). Assume that both tests are of size α . Show that for $\mu > \mu_0$, the power function of the one-sided test is larger than the power function of the two-sided test.

4.6.5. On page 373 Rasmussen (1992) discussed a paired design. A baseball coach paired 20 members of his team by their speed; i.e., each member of the pair has about the same speed. Then for each pair, he randomly chose one member of the pair and told him that if could beat his best time in circling the bases he would give him an award (call this response the time of the “self” member). For the other member of the pair the coach’s instruction was an award if he could beat the time of the other member of the pair (call this response the time of the “rival” member). Each member of the pair knew who his rival was. The data are given below, but are also in the file `selfrival.rda`. Let μ_d be the true difference in times (rival minus self) for a pair. The hypotheses of interest are $H_0 : \mu_d = 0$ versus $H_1 : \mu_d < 0$. The data are in order by pairs, so do not mix the order.

```

16.04 16.80 17.24 16.81 17.11 17.22 17.33 17.82 18.19 17.88

- (a) Obtain comparison boxplots of the data. Comment on the comparison plots. Are there any outliers?
- (b) Compute the paired t -test and obtain the p -value. Are the data significant at the 5% level of significance?
- (c) Obtain a point estimate of μ_d and a 95% confidence interval for it.
- (d) Conclude in terms of the problem.

4.6.6. Verzani (2014), page 323, presented a data set concerning the effect that different dosages of the drug AZT have on patients with HIV. The responses we consider are the p24 antigen levels of HIV patients after their treatment with AZT. Of the 20 HIV patients in the study, 10 were randomly assigned the dosage of 300 mg of AZT while the other 10 were assigned 600 mg. The hypotheses of interest are $H_0 : \Delta = 0$ versus $H_1 : \Delta \neq 0$ where $\Delta = \mu_{600} - \mu_{300}$ and μ_{600} and μ_{300} are the true mean p24 antigen levels under dosages of 600 mg and 300 mg of AZT, respectively. The data are given below but are also available in the file `aztdoses.rda`.

300 mg	284	279	289	292	287	295	285	279	306	298
600 mg	298	307	297	279	291	335	299	300	306	291

- (a) Obtain comparison boxplots of the data. Identify outliers by patient. Comment on the comparison plots.
- (b) Compute the two-sample t -test and obtain the p -value. Are the data significant at the 5% level of significance?
- (c) Obtain a point estimate of Δ and a 95% confidence interval for it.
- (d) Conclude in terms of the problem.

4.6.7. Among the data collected for the World Health Organization air quality monitoring project is a measure of suspended particles in $\mu\text{g}/\text{m}^3$. Let X and Y equal the concentration of suspended particles in $\mu\text{g}/\text{m}^3$ in the city center (commercial district) for Melbourne and Houston, respectively. Using $n = 13$ observations of X and $m = 16$ observations of Y , we test $H_0 : \mu_X = \mu_Y$ against $H_1 : \mu_X < \mu_Y$.

- (a) Define the test statistic and critical region, assuming that the unknown variances are equal. Let $\alpha = 0.05$.
- (b) If $\bar{x} = 72.9$, $s_x = 25.6$, $\bar{y} = 81.7$, and $s_y = 28.3$, calculate the value of the test statistic and state your conclusion.

4.6.8. Let p equal the proportion of drivers who use a seat belt in a country that does not have a mandatory seat belt law. It was claimed that $p = 0.14$. An advertising campaign was conducted to increase this proportion. Two months after the campaign, $y = 104$ out of a random sample of $n = 590$ drivers were wearing their seat belts. Was the campaign successful?

- (a) Define the null and alternative hypotheses.
- (b) Define a critical region with an $\alpha = 0.01$ significance level.
- (c) Determine the approximate p -value and state your conclusion.

4.6.9. In Exercise 4.2.18 we found a confidence interval for the variance σ^2 using the variance S^2 of a random sample of size n arising from $N(\mu, \sigma^2)$, where the mean μ is unknown. In testing $H_0 : \sigma^2 = \sigma_0^2$ against $H_1 : \sigma^2 > \sigma_0^2$, use the critical region defined by $(n-1)S^2/\sigma_0^2 \geq c$. That is, reject H_0 and accept H_1 if $S^2 \geq c\sigma_0^2/(n-1)$. If $n = 13$ and the significance level $\alpha = 0.025$, determine c .

4.6.10. In Exercise 4.2.27, in finding a confidence interval for the ratio of the variances of two normal distributions, we used a statistic S_1^2/S_2^2 , which has an F -distribution when those two variances are equal. If we denote that statistic by F , we can test $H_0 : \sigma_1^2 = \sigma_2^2$ against $H_1 : \sigma_1^2 > \sigma_2^2$ using the critical region $F \geq c$. If $n = 13$, $m = 11$, and $\alpha = 0.05$, find c .

4.7 Chi-Square Tests

In this section we introduce tests of statistical hypotheses called **chi-square tests**. A test of this sort was originally proposed by Karl Pearson in 1900, and it provided one of the earlier methods of statistical inference.

Let the random variable X_i be $N(\mu_i, \sigma_i^2)$, $i = 1, 2, \dots, n$, and let X_1, X_2, \dots, X_n be mutually independent. Thus the joint pdf of these variables is

$$\frac{1}{\sigma_1 \sigma_2 \cdots \sigma_n (2\pi)^{n/2}} \exp \left[-\frac{1}{2} \sum_1^n \left(\frac{x_i - \mu_i}{\sigma_i} \right)^2 \right], \quad -\infty < x_i < \infty.$$

The random variable that is defined by the exponent (apart from the coefficient $-\frac{1}{2}$) is $\sum_1^n [(x_i - \mu_i)/\sigma_i]^2$, and this random variable has a $\chi^2(n)$ distribution. In Section 3.5 we generalized this joint normal distribution of probability to n random variables that are *dependent* and we called the distribution a *multivariate normal distribution*. Theorem 3.5.1 shows a similar result holds for the exponent in the multivariate normal case, also.

Let us now discuss some random variables that have approximate chi-square distributions. Let X_1 be $b(n, p_1)$. Consider the random variable

$$Y = \frac{X_1 - np_1}{\sqrt{np_1(1-p_1)}},$$

which has, as $n \rightarrow \infty$, an approximate $N(0, 1)$ distribution (see Theorem 4.2.1). Furthermore, as discussed in Example 5.3.6, the distribution of Y^2 is approximately $\chi^2(1)$. Let $X_2 = n - X_1$ and let $p_2 = 1 - p_1$. Let $Q_1 = Y^2$. Then Q_1 may be written as

$$\begin{aligned} Q_1 &= \frac{(X_1 - np_1)^2}{np_1(1 - p_1)} = \frac{(X_1 - np_1)^2}{np_1} + \frac{(X_1 - np_1)^2}{n(1 - p_1)} \\ &= \frac{(X_1 - np_1)^2}{np_1} + \frac{(X_2 - np_2)^2}{np_2} \end{aligned} \quad (4.7.1)$$

because $(X_1 - np_1)^2 = (n - X_2 - n + np_2)^2 = (X_2 - np_2)^2$. This result can be generalized as follows.

Let X_1, X_2, \dots, X_{k-1} have a multinomial distribution with the parameters n and p_1, \dots, p_{k-1} , as in Section 3.1. Let $X_k = n - (X_1 + \dots + X_{k-1})$ and let $p_k = 1 - (p_1 + \dots + p_{k-1})$. Define Q_{k-1} by

$$Q_{k-1} = \sum_{i=1}^k \frac{(X_i - np_i)^2}{np_i}.$$

It is proved in a more advanced course that, as $n \rightarrow \infty$, Q_{k-1} has an approximate $\chi^2(k-1)$ distribution. Some writers caution the user of this approximation to be certain that n is large enough so that each np_i , $i = 1, 2, \dots, k$, is at least equal to 5. In any case, it is important to realize that Q_{k-1} does not have a chi-square distribution, only an approximate chi-square distribution.

The random variable Q_{k-1} may serve as the basis of the tests of certain statistical hypotheses which we now discuss. Let the sample space \mathcal{A} of a random experiment be the union of a finite number k of mutually disjoint sets A_1, A_2, \dots, A_k . Furthermore, let $P(A_i) = p_i$, $i = 1, 2, \dots, k$, where $p_k = 1 - p_1 - \dots - p_{k-1}$, so that p_i is the probability that the outcome of the random experiment is an element of the set A_i . The random experiment is to be repeated n independent times and X_i represents the number of times the outcome is an element of set A_i . That is, $X_1, X_2, \dots, X_k = n - X_1 - \dots - X_{k-1}$ are the frequencies with which the outcome is, respectively, an element of A_1, A_2, \dots, A_k . Then the joint pmf of X_1, X_2, \dots, X_{k-1} is the multinomial pmf with the parameters n, p_1, \dots, p_{k-1} . Consider the simple hypothesis (concerning this multinomial pmf) $H_0 : p_1 = p_{10}, p_2 = p_{20}, \dots, p_{k-1} = p_{k-1,0}$ ($p_k = p_{k0} = 1 - p_{10} - \dots - p_{k-1,0}$), where $p_{10}, \dots, p_{k-1,0}$ are specified numbers. It is desired to test H_0 against all alternatives.

If the hypothesis H_0 is true, the random variable

$$Q_{k-1} = \sum_{i=1}^k \frac{(X_i - np_{i0})^2}{np_{i0}}$$

has an approximate chi-square distribution with $k-1$ degrees of freedom. Since, when H_0 is true, np_{i0} is the expected value of X_i , one would feel intuitively that observed values of Q_{k-1} should not be too large if H_0 is true. Our test is then

to reject H_0 if $Q_{k-1} \geq c$. To determine a test with level of significance α , we can use tables of the χ^2 -distribution or a computer package. Using R, we compute the critical value c by `qchisq(1 - alpha, k-1)`. If, then, the hypothesis H_0 is rejected when the observed value of Q_{k-1} is at least as great as c , the test of H_0 has a significance level that is approximately equal to α . Also if q is the realized value of the test statistic Q_{k-1} then the observed significance level of the test is computed in R by `1-pchisq(q, k-1)`. This is frequently called a **goodness-of-fit test**. Some illustrative examples follow.

Example 4.7.1. One of the first six positive integers is to be chosen by a random experiment (perhaps by the cast of a die). Let $A_i = \{x : x = i\}$, $i = 1, 2, \dots, 6$. The hypothesis $H_0 : P(A_i) = p_{i0} = \frac{1}{6}$, $i = 1, 2, \dots, 6$, is tested, at the approximate 5% significance level, against all alternatives. To make the test, the random experiment is repeated under the same conditions, 60 independent times. In this example, $k = 6$ and $np_{i0} = 60(\frac{1}{6}) = 10$, $i = 1, 2, \dots, 6$. Let X_i denote the frequency with which the random experiment terminates with the outcome in A_i , $i = 1, 2, \dots, 6$, and let $Q_5 = \sum_1^6 (X_i - 10)^2 / 10$. Since there are $6 - 1 = 5$ degrees of freedom, the critical value for a level $\alpha = 0.05$ test is `qchisq(0.95, 5) = 11.0705`. Now suppose that the experimental frequencies of A_1, A_2, \dots, A_6 are, respectively, 13, 19, 11, 8, 5, and 4. The observed value of Q_5 is

$$\frac{(13 - 10)^2}{10} + \frac{(19 - 10)^2}{10} + \frac{(11 - 10)^2}{10} + \frac{(8 - 10)^2}{10} + \frac{(5 - 10)^2}{10} + \frac{(4 - 10)^2}{10} = 15.6.$$

Since $15.6 > 11.0705$, the hypothesis $P(A_i) = \frac{1}{6}$, $i = 1, 2, \dots, 6$, is rejected at the (approximate) 5% significance level.

The following R segment computes this test, returning the test statistic and the p -value as shown:

```
ps=rep(1/6,6); x=c(13,19,11,8,5,4); chisq.test(x,p=ps)
X-squared = 15.6, df = 5, p-value = 0.008084.
```

Example 4.7.2. A point is to be selected from the unit interval $\{x : 0 < x < 1\}$ by a random process. Let $A_1 = \{x : 0 < x \leq \frac{1}{4}\}$, $A_2 = \{x : \frac{1}{4} < x \leq \frac{1}{2}\}$, $A_3 = \{x : \frac{1}{2} < x \leq \frac{3}{4}\}$, and $A_4 = \{x : \frac{3}{4} < x < 1\}$. Let the probabilities p_i , $i = 1, 2, 3, 4$, assigned to these sets under the hypothesis be determined by the pdf $2x$, $0 < x < 1$, zero elsewhere. Then these probabilities are, respectively,

$$p_{10} = \int_0^{1/4} 2x \, dx = \frac{1}{16}, \quad p_{20} = \frac{3}{16}, \quad p_{30} = \frac{5}{16}, \quad p_{40} = \frac{7}{16}.$$

Thus the hypothesis to be tested is that p_1, p_2, p_3 , and $p_4 = 1 - p_1 - p_2 - p_3$ have the preceding values in a multinomial distribution with $k = 4$. This hypothesis is to be tested at an approximate 0.025 significance level by repeating the random experiment $n = 80$ independent times under the same conditions. Here the np_{i0} for $i = 1, 2, 3, 4$, are, respectively, 5, 15, 25, and 35. Suppose the observed frequencies of A_1, A_2, A_3 , and A_4 are 6, 18, 20, and 36, respectively. Then the observed value

of $Q_3 = \sum_1^4 (X_i - np_{i0})^2 / (np_{i0})$ is

$$\frac{(6-5)^2}{5} + \frac{(18-15)^2}{15} + \frac{(20-25)^2}{25} + \frac{(36-35)^2}{35} = \frac{64}{35} = 1.83.$$

The following R segment calculates the test and p -value:

```
x=c(6,18,20,36); ps=c(1,3,5,7)/16; chisq.test(x,p=ps)
X-squared = 1.8286, df = 3, p-value = 0.6087
```

Hence, we fail to reject H_0 at level 0.0250. ■

Thus far we have used the chi-square test when the hypothesis H_0 is a simple hypothesis. More often we encounter hypotheses H_0 in which the multinomial probabilities p_1, p_2, \dots, p_k are not completely specified by the hypothesis H_0 . That is, under H_0 , these probabilities are functions of unknown parameters. For an illustration, suppose that a certain random variable Y can take on any real value. Let us partition the space $\{y : -\infty < y < \infty\}$ into k mutually disjoint sets A_1, A_2, \dots, A_k so that the events A_1, A_2, \dots, A_k are mutually exclusive and exhaustive. Let H_0 be the hypothesis that Y is $N(\mu, \sigma^2)$ with μ and σ^2 unspecified. Then each

$$p_i = \int_{A_i} \frac{1}{\sqrt{2\pi}\sigma} \exp[-(y-\mu)^2/2\sigma^2] dy, \quad i = 1, 2, \dots, k,$$

is a function of the unknown parameters μ and σ^2 . Suppose that we take a random sample Y_1, \dots, Y_n of size n from this distribution. If we let X_i denote the frequency of A_i , $i = 1, 2, \dots, k$, so that $X_1 + X_2 + \dots + X_k = n$, the random variable

$$Q_{k-1} = \sum_{i=1}^k \frac{(X_i - np_i)^2}{np_i}$$

cannot be computed once X_1, \dots, X_k have been observed, since each p_i , and hence Q_{k-1} , is a function of μ and σ^2 . Accordingly, choose the values of μ and σ^2 that minimize Q_{k-1} . These values depend upon the observed $X_1 = x_1, \dots, X_k = x_k$ and are called **minimum chi-square estimates** of μ and σ^2 . These point estimates of μ and σ^2 enable us to compute numerically the estimates of each p_i . Accordingly, if these values are used, Q_{k-1} can be computed once Y_1, Y_2, \dots, Y_n , and hence X_1, X_2, \dots, X_k , are observed. However, a very important aspect of the fact, which we accept without proof, is that now Q_{k-1} is approximately $\chi^2(k-3)$. That is, the number of degrees of freedom of the approximate chi-square distribution of Q_{k-1} is reduced by one for each parameter estimated by the observed data. This statement applies not only to the problem at hand but also to more general situations. Two examples are now be given. The first of these examples deals with the test of the hypothesis that two multinomial distributions are the same.

Remark 4.7.1. In many cases, such as that involving the mean μ and the variance σ^2 of a normal distribution, minimum chi-square estimates are difficult to compute. Other estimates, such as the maximum likelihood estimates of Example 4.1.3, $\hat{\mu} = \bar{Y}$ and $\hat{\sigma}^2 = (n-1)S^2/n$, are used to evaluate p_i and Q_{k-1} . In general, Q_{k-1} is not minimized by maximum likelihood estimates, and thus its computed value

is somewhat greater than it would be if minimum chi-square estimates are used. Hence, when comparing it to a critical value listed in the chi-square table with $k - 3$ degrees of freedom, there is a greater chance of rejection than there would be if the actual minimum of Q_{k-1} is used. Accordingly, the approximate significance level of such a test may be higher than the p -value as calculated in the χ^2 -analysis. This modification should be kept in mind and, if at all possible, each p_i should be estimated using the frequencies X_1, \dots, X_k rather than directly using the observations Y_1, Y_2, \dots, Y_n of the random sample. ■

Example 4.7.3. In this example, we consider two multinomial distributions with parameters $n_j, p_{1j}, p_{2j}, \dots, p_{kj}$ and $j = 1, 2$, respectively. Let X_{ij} , $i = 1, 2, \dots, k$, $j = 1, 2$, represent the corresponding frequencies. If n_1 and n_2 are large and the observations from one distribution are independent of those from the other, the random variable

$$\sum_{j=1}^2 \sum_{i=1}^k \frac{(X_{ij} - n_j p_{ij})^2}{n_j p_{ij}}$$

is the sum of two independent random variables each of which we treat as though it were $\chi^2(k - 1)$; that is, the random variable is approximately $\chi^2(2k - 2)$. Consider the hypothesis

$$H_0 : p_{11} = p_{12}, p_{21} = p_{22}, \dots, p_{k1} = p_{k2},$$

where each $p_{i1} = p_{i2}$, $i = 1, 2, \dots, k$, is unspecified. Thus we need point estimates of these parameters. The maximum likelihood estimator of $p_{i1} = p_{i2}$, based upon the frequencies X_{ij} , is $(X_{i1} + X_{i2})/(n_1 + n_2)$, $i = 1, 2, \dots, k$. Note that we need only $k - 1$ point estimates, because we have a point estimate of $p_{k1} = p_{k2}$ once we have point estimates of the first $k - 1$ probabilities. In accordance with the fact that has been stated, the random variable

$$Q_{k-1} = \sum_{j=1}^2 \sum_{i=1}^k \frac{\{X_{ij} - n_j[(X_{i1} + X_{i2})/(n_1 + n_2)]\}^2}{n_j[(X_{i1} + X_{i2})/(n_1 + n_2)]}$$

has an approximate χ^2 distribution with $2k - 2 - (k - 1) = k - 1$ degrees of freedom. Thus we are able to test the hypothesis that two multinomial distributions are the same. For a specified level α , the hypothesis H_0 is rejected when the computed value of Q_{k-1} exceeds the $1 - \alpha$ quantile of a χ^2 -distribution with $k - 1$ degrees of freedom. This test is often called the chi-square test for **homogeneity** (the null is equivalent to **homogeneous distributions**). ■

The second example deals with the subject of **contingency tables**.

Example 4.7.4. Let the result of a random experiment be classified by two attributes (such as the color of the hair and the color of the eyes). That is, one attribute of the outcome is one and only one of certain mutually exclusive and exhaustive events, say A_1, A_2, \dots, A_a ; and the other attribute of the outcome is also one and only one of certain mutually exclusive and exhaustive events, say B_1, B_2, \dots, B_b . Let $p_{ij} = P(A_i \cap B_j)$, $i = 1, 2, \dots, a$; $j = 1, 2, \dots, b$. The random

experiment is repeated n independent times and X_{ij} denotes the frequency of the event $A_i \cap B_j$. Since there are $k = ab$ such events as $A_i \cap B_j$, the random variable

$$Q_{ab-1} = \sum_{j=1}^b \sum_{i=1}^a \frac{(X_{ij} - np_{ij})^2}{np_{ij}}$$

has an approximate chi-square distribution with $ab - 1$ degrees of freedom, provided that n is large. Suppose that we wish to test the independence of the A and the B attributes, i.e., the hypothesis $H_0 : P(A_i \cap B_j) = P(A_i)P(B_j)$, $i = 1, 2, \dots, a$; $j = 1, 2, \dots, b$. Let us denote $P(A_i)$ by p_i . and $P(B_j)$ by p_j . It follows that

$$p_{i\cdot} = \sum_{j=1}^b p_{ij}, \quad p_{\cdot j} = \sum_{i=1}^a p_{ij}, \quad \text{and} \quad 1 = \sum_{j=1}^b \sum_{i=1}^a p_{ij} = \sum_{j=1}^b p_{\cdot j} = \sum_{i=1}^a p_{i\cdot}.$$

Then the hypothesis can be formulated as $H_0 : p_{ij} = p_{i\cdot}p_{\cdot j}$, $i = 1, 2, \dots, a$; $j = 1, 2, \dots, b$. To test H_0 , we can use Q_{ab-1} with p_{ij} replaced by $p_{i\cdot}p_{\cdot j}$. But if $p_{i\cdot}$, $i = 1, 2, \dots, a$, and $p_{\cdot j}$, $j = 1, 2, \dots, b$, are unknown, as they frequently are in applications, we cannot compute Q_{ab-1} once the frequencies are observed. In such a case, we estimate these unknown parameters by

$$\hat{p}_{i\cdot} = \frac{X_{i\cdot}}{n}, \quad \text{where } X_{i\cdot} = \sum_{j=1}^b X_{ij}, \quad \text{for } i = 1, 2, \dots, a,$$

and

$$\hat{p}_{\cdot j} = \frac{X_{\cdot j}}{n}, \quad \text{where } X_{\cdot j} = \sum_{i=1}^a X_{ij}, \quad \text{for } j = 1, 2, \dots, b.$$

Since $\sum_i p_{i\cdot} = \sum_j p_{\cdot j} = 1$, we have estimated only $a-1+b-1 = a+b-2$ parameters. So if these estimates are used in Q_{ab-1} , with $p_{ij} = p_{i\cdot}p_{\cdot j}$, then, according to the rule that has been stated in this section, the random variable

$$\sum_{j=1}^b \sum_{i=1}^a \frac{[X_{ij} - n(X_{i\cdot}/n)(X_{\cdot j}/n)]^2}{n(X_{i\cdot}/n)(X_{\cdot j}/n)} \tag{4.7.2}$$

has an approximate chi-square distribution with $ab - 1 - (a + b - 2) = (a - 1)(b - 1)$ degrees of freedom provided that H_0 is true. For a specified level α , the hypothesis H_0 is then rejected if the computed value of this statistic exceeds the $1 - \alpha$ quantile of a χ^2 -distribution with $(a - 1)(b - 1)$ degrees of freedom. This is the **χ^2 -test for independence**.

For an illustration, reconsider Example 4.1.5 in which we presented data on hair color of Scottish children. The eye colors of the children were also recorded. The complete data are in the following contingency table (with additionally the marginal sums). The contingency table is also in the file `scotteyehair.rda`.

	Fair	Red	Medium	Dark	Black	Margin
Blue	1368	170	1041	398	1	2978
Light	2577	474	2703	932	11	6697
Medium	1390	420	3826	1842	33	7511
Dark	454	255	1848	2506	112	5175
Margin	5789	1319	9418	5678	157	22361

The table indicates that hair and eye color are dependent random variables. For example, the observed frequency of children with blue eyes and black hair is 1 while the expected frequency under independence is $2978 \times 157/22361 = 20.9$. The contribution to the test statistic from this one cell is $(1 - 20.9)^2/20.9 = 19.95$ that nearly exceeds the test statistic's χ^2 critical value at level 0.05, which is $\text{qchisq}(.95, 12) = 21.026$. The χ^2 -test statistic for independence is tedious to compute and the reader is advised to use a statistical package. For R, assume that the contingency table without margin sums is in the matrix `scotteyehair`. Then the code `chisq.test(scotteyehair)` returns the χ^2 test statistic and the *p*-value as: `X-squared = 3683.9, df = 12, p-value < 2.2e-16`. Thus the result is highly significant. Based on this study, hair color and eye color of Scottish children are dependent on one another. To investigate where the dependence is the strongest in a contingency table, we recommend considering the table of expected frequencies and the table of **Pearson residuals**. The later are the square roots (with the sign of the numerators) of the summands in expression (4.7.2) defining the test statistic. The sum of the squared Pearson residuals equals the χ^2 -test statistic. In R, the following code obtains both of these items:

```
fit = chisq.test(scotteyehair); fit$expected; fit$residual
```

Based on running this code, the largest residual is 32.8 for the cell dark hair and dark eyes. The observed frequency is 2506 while the expected frequency under independence is 1314. ■

In each of the four examples of this section, we have indicated that the statistic used to test the hypothesis H_0 has an approximate chi-square distribution, provided that n is sufficiently large and H_0 is true. To compute the power of any of these tests for values of the parameters not described by H_0 , we need the distribution of the statistic when H_0 is not true. In each of these cases, the statistic has an approximate distribution called a **noncentral chi-square distribution**. The noncentral chi-square distribution is discussed later in Section 9.3.

EXERCISES

4.7.1. Consider Example 4.7.2. Suppose the observed frequencies of A_1, \dots, A_4 are 20, 30, 92, and 105, respectively. Modify the R code given in the example to calculate the test for these new frequencies. Report the *p*-value.

4.7.2. A number is to be selected from the interval $\{x : 0 < x < 2\}$ by a random process. Let $A_i = \{x : (i-1)/2 < x \leq i/2\}$, $i = 1, 2, 3$, and let $A_4 = \{x : \frac{3}{2} < x < 2\}$. For $i = 1, 2, 3, 4$, suppose a certain hypothesis assigns probabilities p_{i0} to these sets in accordance with $p_{i0} = \int_{A_i} (\frac{1}{2})(2-x) dx$, $i = 1, 2, 3, 4$. This

hypothesis (concerning the multinomial pdf with $k = 4$) is to be tested at the 5% level of significance by a chi-square test. If the observed frequencies of the sets A_i , $i = 1, 2, 3, 4$, are respectively, 30, 30, 10, 10, would H_0 be accepted at the (approximate) 5% level of significance? Use R code similar to that of Example 4.7.2 for the computation.

4.7.3. Define the sets $A_1 = \{x : -\infty < x \leq 0\}$, $A_i = \{x : i - 2 < x \leq i - 1\}$, $i = 2, \dots, 7$, and $A_8 = \{x : 6 < x < \infty\}$. A certain hypothesis assigns probabilities p_{i0} to these sets A_i in accordance with

$$p_{i0} = \int_{A_i} \frac{1}{2\sqrt{2\pi}} \exp\left[-\frac{(x-3)^2}{2(4)}\right] dx, \quad i = 1, 2, \dots, 7, 8.$$

This hypothesis (concerning the multinomial pdf with $k = 8$) is to be tested, at the 5% level of significance, by a chi-square test. If the observed frequencies of the sets A_i , $i = 1, 2, \dots, 8$, are, respectively, 60, 96, 140, 210, 172, 160, 88, and 74, would H_0 be accepted at the (approximate) 5% level of significance? Use R code similar to that discussed in Example 4.7.2. The probabilities are easily computed in R; for example, $p_{30} = \text{pnorm}(2, 3, 2) - \text{pnorm}(1, 3, 2)$.

4.7.4. A die was cast $n = 120$ independent times and the following data resulted:

Spots Up	1	2	3	4	5	6
Frequency	b	20	20	20	20	$40 - b$

If we use a chi-square test, for what values of b would the hypothesis that the die is unbiased be rejected at the 0.025 significance level?

4.7.5. Consider the problem from genetics of crossing two types of peas. The Mendelian theory states that the probabilities of the classifications (a) round and yellow, (b) wrinkled and yellow, (c) round and green, and (d) wrinkled and green are $\frac{9}{16}$, $\frac{3}{16}$, $\frac{3}{16}$, and $\frac{1}{16}$, respectively. If, from 160 independent observations, the observed frequencies of these respective classifications are 86, 35, 26, and 13, are these data consistent with the Mendelian theory? That is, test, with $\alpha = 0.01$, the hypothesis that the respective probabilities are $\frac{9}{16}$, $\frac{3}{16}$, $\frac{3}{16}$, and $\frac{1}{16}$.

4.7.6. Two different teaching procedures were used on two different groups of students. Each group contained 100 students of about the same ability. At the end of the term, an evaluating team assigned a letter grade to each student. The results were tabulated as follows.

Group	Grade					Total
	A	B	C	D	F	
I	15	25	32	17	11	100
II	9	18	29	28	16	100

If we consider these data to be independent observations from two respective multinomial distributions with $k = 5$, test at the 5% significance level the hypothesis

Table 4.7.1: Contingency Table for Type of Crime and Alcoholic Status Data

Crime	Alcoholic	Non-Alcoholic
Arson	50	43
Rape	88	62
Violence	155	110
Theft	379	300
Coining	18	14
Fraud	63	144

that the two distributions are the same (and hence the two teaching procedures are equally effective). For computation in R, use

```
r1=c(15,25,32,17,11);r2=c(9,18,29,28,16);mat=rbind(r1,r2)
chisq.test(mat)
```

4.7.7. Kloke and McKean (2014) present a data set concerning crime and alcoholism. The data they discuss is in Table 4.7.1. It contains the frequencies of criminals who committed certain crimes and whether or not they are alcoholics. The data are also in the file `crimealk.rda`.

- (a) Using code similar to that given in Exercise 4.7.6, compute the χ^2 -test for independence between type of crime and alcoholic status. Conclude in terms of the problem, using the p -value.
- (b) Use the Pearson residuals to determine which part of the table contains the strongest information concerning dependence.
- (c) Use a χ^2 -test to confirm your suspicions in Part (b). This is a conditional test based on the data, but, in practice, such tests are used for planning future studies.

4.7.8. Let the result of a random experiment be classified as one of the mutually exclusive and exhaustive ways A_1, A_2, A_3 and also as one of the mutually exhaustive ways B_1, B_2, B_3, B_4 . Say that 180 independent trials of the experiment result in the following frequencies:

	B_1	B_2	B_3	B_4
A_1	$15 - 3k$	$15 - k$	$15 + k$	$15 + 3k$
A_2	15	15	15	15
A_3	$15 + 3k$	$15 + k$	$15 - k$	$15 - 3k$

where k is one of the integers 0, 1, 2, 3, 4, 5. What is the smallest value of k that leads to the rejection of the independence of the A attribute and the B attribute at the $\alpha = 0.05$ significance level?

4.7.9. It is proposed to fit the Poisson distribution to the following data:

x	0	1	2	3	$3 < x$
Frequency	20	40	16	18	6

- (a) Compute the corresponding chi-square goodness-of-fit statistic.

Hint: In computing the mean, treat $3 < x$ as $x = 4$.

- (b) How many degrees of freedom are associated with this chi-square?

- (c) Do these data result in the rejection of the Poisson model at the $\alpha = 0.05$ significance level?

4.8 The Method of Monte Carlo

In this section we introduce the concept of generating observations from a specified distribution or sample. This is often called **Monte Carlo** generation. This technique has been used for simulating complicated processes and investigating finite sample properties of statistical methodology for some time now. In the last 30 years, however, this has become a very important concept in modern statistics in the realm of inference based on the bootstrap (resampling) and modern Bayesian methods. We repeatedly make use of this concept throughout the book.

For the most part, a generator of random uniform observations is all that is needed. It is not easy to construct a device that generates random uniform observations. However, there has been considerable work done in this area, not only in the construction of such generators, but in the testing of their accuracy as well. Most statistical software packages, such as R, have reliable uniform generators.

Suppose then we have a device capable of generating a stream of independent and identically distributed observations from a uniform $(0, 1)$ distribution. For example, the following command generates 10 such observations in the language R: `runif(10)`. In this command the `r` stands for random, the `unif` stands for uniform, the 10 stands for the number of observations requested, and the lack of additional arguments means that the standard uniform $(0, 1)$ generator is used.

For observations from a discrete distribution, often a uniform generator suffices. For a simple example, consider an experiment where a fair six-sided die is rolled and the random variable X is 1 if the upface is a “low number,” namely $\{1, 2\}$; otherwise, $X = 0$. Note that the mean of X is $\mu = 1/3$. If U has a uniform $(0, 1)$ distribution, then X can be realized as

$$X = \begin{cases} 1 & \text{if } 0 < U \leq 1/3 \\ 0 & \text{if } 1/3 < U < 1. \end{cases}$$

Using the command above, we used the following R code to generate 10 observations from this experiment:

```
n = 10; u = runif(n); x = rep(0,n); x[u < 1/3] = 1; x
```

The following table displays the results.

u_i	0.4743	0.7891	0.5550	0.9693	0.0299
x_i	0	0	0	0	1
u_i	0.8425	0.6012	0.1009	0.0545	0.4677
x_i	0	0	1	1	0

Note that observations form a realization of a random sample X_1, \dots, X_{10} drawn from the distribution of X . For these 10 observations, the realized value of the statistic \bar{X} is $\bar{x} = 0.3$.

Example 4.8.1 (Estimation of π). Consider the experiment where a pair of numbers (U_1, U_2) is chosen at random in the unit square, as shown in Figure 4.8.1; that is, U_1 and U_2 are iid uniform $(0, 1)$ random variables. Since the point is chosen at random, the probability of (U_1, U_2) lying within the unit circle is $\pi/4$. Let X be the random variable,

$$X = \begin{cases} 1 & \text{if } U_1^2 + U_2^2 < 1 \\ 0 & \text{otherwise.} \end{cases}$$

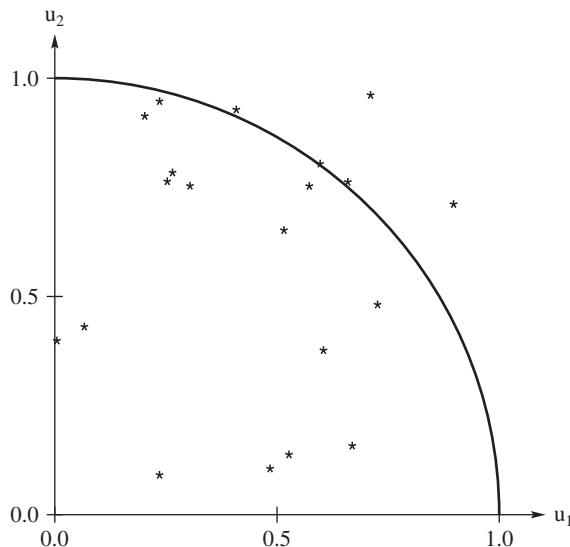

Figure 4.8.1: Unit square with the first quadrant of the unit circle, Example 4.8.1.

Hence the mean of X is $\mu = \pi/4$. Now suppose π is unknown. One way of estimating π is to repeat the experiment n independent times, hence, obtaining a random sample X_1, \dots, X_n on X . The statistic $4\bar{X}$ is an unbiased estimator of π . The R function `piest` repeats this experiment n times, returning the estimate of π . This function and other R functions discussed in this chapter are available at the site discussed in the Preface. Figure 4.8.1 shows 20 realizations of this experiment. Note that of the 20 points, 15 fall within the unit circle. Hence our estimate of π is $4(15/20) = 3.00$. We ran this code for various values of n with the following results:

n	100	500	1000	10,000	100,000
$4\bar{x}$	3.24	3.072	3.132	3.138	3.13828
$1.96 \cdot 4\sqrt{\bar{x}(1-\bar{x})/n}$	0.308	0.148	0.102	0.032	0.010

We can use the large sample confidence interval derived in Section 4.2 to estimate the error of estimation. The corresponding 95% confidence interval for π is

$$\left(4\bar{x} - 1.96 \cdot 4\sqrt{\bar{x}(1-\bar{x})/n}, 4\bar{x} + 1.96 \cdot 4\sqrt{\bar{x}(1-\bar{x})/n}\right). \quad (4.8.1)$$

The last row of the above table contains the error part of the confidence intervals. Notice that all five confidence intervals trapped the true value of π . ■

What about continuous random variables? For these we have the following theorem:

Theorem 4.8.1. *Suppose the random variable U has a uniform $(0, 1)$ distribution. Let F be a continuous distribution function. Then the random variable $X = F^{-1}(U)$ has distribution function F .*

Proof: Recall from the definition of a uniform distribution that U has the distribution function $F_U(u) = u$ for $u \in (0, 1)$. Using this, the distribution-function technique, and assuming that $F(x)$ is strictly monotone, the distribution function of X is

$$\begin{aligned} P[X \leq x] &= P[F^{-1}(U) \leq x] \\ &= P[U \leq F(x)] \\ &= F(x), \end{aligned}$$

which proves the theorem. ■

In the proof, we assumed that $F(x)$ was strictly monotone. As Exercise 4.8.13 shows, we can weaken this.

We can use this theorem to generate realizations (observations) of many different random variables. For example, suppose X has the $\Gamma(1, \beta)$ -distribution. Suppose we have a uniform generator and we want to generate a realization of X . The distribution function of X is

$$F(x) = 1 - e^{-x/\beta}, \quad x > 0.$$

Hence the inverse of the distribution function is given by

$$F^{-1}(u) = -\beta \log(1-u), \quad 0 < u < 1. \quad (4.8.2)$$

So if U has the uniform $(0, 1)$ distribution, then $X = -\beta \log(1-U)$ has the $\Gamma(1, \beta)$ -distribution. For instance, suppose $\beta = 1$ and our uniform generator generated the following stream of uniform observations:

$$0.473, 0.858, 0.501, 0.676, 0.240.$$

Then the corresponding stream of exponential observations is

$$0.641, 1.95, 0.696, 1.13, 0.274.$$

As the next example shows, we can generate Poisson realizations using this exponential generation.

Example 4.8.2 (Simulating Poisson Processes). Let X be the number of occurrences of an event over a unit of time and assume that it has a Poisson distribution with mean λ , (3.2.1). Let T_1, T_2, T_3, \dots be the interarrival times of the occurrences. Recall from Remark 3.3.1 that T_1, T_2, T_3, \dots are iid with the common $\Gamma(1, 1/\lambda)$ -distribution. Note that $X = k$ if and only if $\sum_{j=1}^k T_j \leq 1$ and $\sum_{j=1}^{k+1} T_j > 1$. Using this fact and the generation of $\Gamma(1, 1/\lambda)$ variates discussed above, the following algorithm generates a realization of X (assume that the uniforms generated are independent of one another).

1. Set $X = 0$ and $T = 0$.
2. Generate U uniform $(0, 1)$ and let $Y = -(1/\lambda) \log(1 - U)$.
3. Set $T = T + Y$.
4. If $T > 1$, output X ;
else set $X = X + 1$ and go to step 2.

The R function `poisrand` provides an implementation of this algorithm, generating n simulations of a Poisson distribution with parameter λ . As an illustration, we obtained 1000 realizations from a Poisson distribution with $\lambda = 5$ by running R with the R code `temp = poisrand(1000, 5)`, which stores the realizations in the vector `temp`. The sample average of these realizations is computed by the command `mean(temp)`. In the situation that we ran, the realized mean was 4.895. ■

Example 4.8.3 (Monte Carlo Integration). Suppose we want to obtain the integral $\int_a^b g(x) dx$ for a continuous function g over the closed and bounded interval $[a, b]$. If the antiderivative of g does not exist, then numerical integration is in order. A simple numerical technique is the method of Monte Carlo. We can write the integral as

$$\int_a^b g(x) dx = (b - a) \int_a^b g(x) \frac{1}{b - a} dx = (b - a) E[g(X)],$$

where X has the uniform (a, b) distribution. The Monte Carlo technique is then to generate a random sample X_1, \dots, X_n of size n from the uniform (a, b) distribution and compute $Y_i = (b - a)g(X_i)$. Then \bar{Y} is an unbiased estimator of $\int_a^b g(x) dx$. ■

Example 4.8.4 (Estimation of π by Monte Carlo Integration). For a numerical example, reconsider the estimation of π . Instead of the experiment described in Example 4.8.1, we use the method of Monte Carlo integration. Let $g(x) = 4\sqrt{1 - x^2}$ for $0 < x < 1$. Then

$$\pi = \int_0^1 g(x) dx = E[g(X)],$$

where X has the uniform $(0, 1)$ distribution. Hence we need to generate a random sample X_1, \dots, X_n from the uniform $(0, 1)$ distribution and form $Y_i = 4\sqrt{1 - X_i^2}$.

Then \bar{Y} is a unbiased estimator of π . Note that \bar{Y} is estimating a mean, so the large sample confidence interval (4.2.6) derived in Example 4.2.2 for means can be used to estimate the error of estimation. Recall that this 95% confidence interval is given by

$$(\bar{y} - 1.96s/\sqrt{n}, \bar{y} + 1.96s/\sqrt{n}),$$

where s is the value of the sample standard deviation. We coded this algorithm in the R function `piest2`. The table below gives the results for estimates of π for various runs of different sample sizes along with the confidence intervals.

n	100	1000	10,000	100,000
\bar{y}	3.217849	3.103322	3.135465	3.142066
$\bar{y} - 1.96(s/\sqrt{n})$	3.054664	3.046330	3.118080	3.136535
$\bar{y} + 1.96(s/\sqrt{n})$	3.381034	3.160314	3.152850	3.147597

Note that for each experiment the confidence interval trapped π . ■

Numerical integration techniques have made great strides over the last 30 years. But the simplicity of integration by Monte Carlo still makes it a powerful technique.

As Theorem 4.8.1 shows, if we can obtain $F_X^{-1}(u)$ in closed form, then we can easily generate observations with cdf F_X . In many cases where this is not possible, techniques have been developed to generate observations. Note that the normal distribution serves as an example of such a case, and, in the next example, we show how to generate normal observations. In Section 4.8.1, we discuss an algorithm that can be adapted for many of these cases.

Example 4.8.5 (Generating Normal Observations). To simulate normal variables, Box and Muller (1958) suggested the following procedure. Let Y_1, Y_2 be a random sample from the uniform distribution over $0 < y < 1$. Define X_1 and X_2 by

$$\begin{aligned} X_1 &= (-2 \log Y_1)^{1/2} \cos(2\pi Y_2), \\ X_2 &= (-2 \log Y_1)^{1/2} \sin(2\pi Y_2). \end{aligned}$$

This transformation is one-to-one and maps $\{(y_1, y_2) : 0 < y_1 < 1, 0 < y_2 < 1\}$ onto $\{(x_1, x_2) : -\infty < x_1 < \infty, -\infty < x_2 < \infty\}$ except for sets involving $x_1 = 0$ and $x_2 = 0$, which have probability zero. The inverse transformation is given by

$$\begin{aligned} y_1 &= \exp\left(-\frac{x_1^2 + x_2^2}{2}\right), \\ y_2 &= \frac{1}{2\pi} \arctan \frac{x_2}{x_1}. \end{aligned}$$

This has the Jacobian

$$\begin{aligned} J &= \begin{vmatrix} (-x_1) \exp\left(-\frac{x_1^2 + x_2^2}{2}\right) & (-x_2) \exp\left(-\frac{x_1^2 + x_2^2}{2}\right) \\ -x_2/x_1^2 & \frac{1}{x_1} \end{vmatrix} \\ &= \frac{-(1 + x_2^2/x_1^2) \exp\left(-\frac{x_1^2 + x_2^2}{2}\right)}{(2\pi)(1 + x_2^2/x_1^2)} = \frac{-\exp\left(-\frac{x_1^2 + x_2^2}{2}\right)}{2\pi}. \end{aligned}$$

Since the joint pdf of Y_1 and Y_2 is 1 on $0 < y_1 < 1, 0 < y_2 < 1$, and zero elsewhere, the joint pdf of X_1 and X_2 is

$$\frac{\exp\left(-\frac{x_1^2 + x_2^2}{2}\right)}{2\pi}, \quad -\infty < x_1 < \infty, \quad -\infty < x_2 < \infty.$$

That is, X_1 and X_2 are independent, standard normal random variables. One of the most commonly used normal generators is a variant of the above procedure called the Marsaglia and Bray (1964) algorithm; see Exercise 4.8.21. ■

Observations from a contaminated normal distribution, discussed in Section 3.4.1, can easily be generated using a normal generator and a uniform generator. We close this section by estimating via Monte Carlo the significance level of a t -test when the underlying distribution is a contaminated normal.

Example 4.8.6. Let X be a random variable with mean μ and consider the hypotheses

$$H_0 : \mu = 0 \text{ versus } H_1 : \mu > 0. \quad (4.8.3)$$

Suppose we decide to base this test on a sample of size $n = 20$ from the distribution of X , using the t -test with rejection rule

$$\text{Reject } H_0 : \mu = 0 \text{ in favor of } H_1 : \mu > 0 \text{ if } t > t_{.05,19} = 1.729, \quad (4.8.4)$$

where $t = \bar{x}/(s/\sqrt{20})$ and \bar{x} and s are the sample mean and standard deviation, respectively. If X has a normal distribution, then this test has level 0.05. But what if X does not have a normal distribution? In particular, for this example, suppose X has the contaminated normal distribution given by (3.4.17) with $\epsilon = 0.25$ and $\sigma_c = 25$; that is, 75% of the time an observation is generated by a standard normal distribution, while 25% of the time it is generated by a normal distribution with mean 0 and standard deviation 25. Hence the mean of X is 0, so H_0 is true. To obtain the exact significance level of the test would be quite complicated. We would have to obtain the distribution of t when X has this contaminated normal distribution. As an alternative, we estimate the level (and the error of estimation) by simulation. Let N be the number of simulations. The following algorithm gives the steps of our simulation:

1. Set $k = 1, I = 0$.
2. Simulate a random sample of size 20 from the distribution of X .
3. Based on this sample, compute the test statistic t .
4. If $t > 1.729$, increase I by 1.
5. If $k = N$; go to step 6; else increase k by 1 and go to step 2.
6. Compute $\hat{\alpha} = I/N$ and the approximate error = $1.96\sqrt{\hat{\alpha}(1 - \hat{\alpha})/N}$.

Then $\hat{\alpha}$ is our simulated estimate of α and the half-width of a confidence interval for α serves as our estimate of the error of estimation.

The R function `empalphacn` implements this algorithm. We ran it for $N = 10,000$ obtaining the results:

No. Simulat.	Empirical $\hat{\alpha}$	Error	95% CI for α
10,000	0.0412	0.0039	(0.0373, 0.0451)

Based on these results, the t -test appears to be conservative when the sample is drawn from this contaminated normal distribution. ■

4.8.1 Accept–Reject Generation Algorithm

In this section, we develop the **accept–reject** procedure that can often be used to simulate random variables whose inverse cdf cannot be obtained in closed form. Let X be a continuous random variable with pdf $f(x)$. For this discussion, we call this pdf the *target* pdf. Suppose it is relatively easy to generate an observation of the random variable Y which has pdf $g(x)$ and that for some constant M we have

$$f(x) \leq Mg(x), \quad -\infty < x < \infty. \quad (4.8.5)$$

We call $g(x)$ the **instrumental** pdf. For clarity, we write the accept–reject as an algorithm:

Algorithm 4.8.1 (Accept–Reject Algorithm). *Let $f(x)$ be a pdf. Suppose that Y is a random variable with pdf $g(y)$, U is a random variable with a uniform(0, 1) distribution, Y and U are independent, and (4.8.5) holds. The following algorithm generates a random variable X with pdf $f(x)$.*

1. Generate Y and U .
2. If $U \leq \frac{f(Y)}{Mg(Y)}$, then take $X = Y$. Otherwise return to step 1.
3. X has pdf $f(x)$.

Proof of the validity of the algorithm: Let $-\infty < x < \infty$. Then

$$\begin{aligned} P[X \leq x] &= P\left[Y \leq x \mid U \leq \frac{f(Y)}{Mg(Y)}\right] \\ &= \frac{P\left[Y \leq x, U \leq \frac{f(Y)}{Mg(Y)}\right]}{P\left[U \leq \frac{f(Y)}{Mg(Y)}\right]} \\ &= \frac{\int_{-\infty}^x \left[\int_0^{f(y)/Mg(y)} du \right] g(y) dy}{\int_{-\infty}^{\infty} \left[\int_0^{f(y)/Mg(y)} du \right] g(y) dy} \end{aligned} \quad (4.8.6)$$

$$= \frac{\int_{-\infty}^x \frac{f(y)}{Mg(y)} g(y) dy}{\int_{-\infty}^{\infty} \frac{f(y)}{Mg(y)} g(y) dy} \quad (4.8.7)$$

$$= \int_{-\infty}^x f(y) dy.$$

Hence, by differentiating both sides, we find that the pdf of X is $f(x)$. ■

There are two facts worth noting. First, the probability of an acceptance in the algorithm is $1/M$. This can be seen in the derivation in the proof of the theorem. Just consider the denominators in the derivation which show that

$$P \left[U \leq \frac{f(Y)}{Mg(Y)} \right] = \frac{1}{M}. \quad (4.8.8)$$

Hence, for efficiency of the algorithm we want M as small as possible. Secondly, normalizing constants of the two pdfs $f(x)$ and $g(x)$ can be ignored. For example, if $f(x) = kh(x)$ and $g(x) = ct(x)$ for constants c and k , then we can use the rule

$$h(x) \leq M_2 t(x), \quad -\infty < x < \infty, \quad (4.8.9)$$

and change the ratio in step 2 of the algorithm to $U \leq h(Y)/[M_2 t(Y)]$. It follows directly that expression (4.8.5) holds if and only if expression (4.8.9) holds where $M_2 = cM/k$. This often simplifies the use of the accept-reject algorithm.

We next present two examples of the accept-reject algorithm. The first example offers a normal generator where the instrumental random variable, Y , has a Cauchy distribution. The second example shows how all gamma distributions can be generated.

Example 4.8.7. Suppose that X is a normally distributed random variable with pdf $\phi(x) = (2\pi)^{-1/2} \exp\{-x^2/2\}$ and Y has a Cauchy distribution with pdf $g(x) = \pi^{-1}(1+x^2)^{-1}$. As Exercise 4.8.9 shows, the Cauchy distribution is easy to simulate because its inverse cdf is a known function. Ignoring normalizing constants, the ratio to bound is

$$\frac{f(x)}{g(x)} \propto (1+x^2) \exp\{-x^2/2\}, \quad -\infty < x < \infty. \quad (4.8.10)$$

As Exercise 4.8.17 shows, the derivative of this ratio is $-x \exp\{-x^2/2\}(x^2 - 1)$, which has critical values at ± 1 . These values provide maxima to (4.8.10). Hence,

$$(1+x^2) \exp\{-x^2/2\} \leq 2 \exp\{-1/2\} = 1.213,$$

so $M_2 = 1.213$. Hence, from the above discussion, $M = (\pi/\sqrt{2\pi})1.213 = 1.520$. Hence, the acceptance rate of the algorithm is $1/M = 0.6577$. ■

Example 4.8.8. Suppose we want to generate observations from a $\Gamma(\alpha, \beta)$. First, if Y has a $\Gamma(\alpha, 1)$ -distribution then βY has a $\Gamma(\alpha, \beta)$ -distribution. Hence, we need only consider $\Gamma(\alpha, 1)$ distributions. So let X have a $\Gamma(\alpha, 1)$ -distribution. If α is a positive integer then by Theorem 3.3.1 we can write X as

$$X = T_1 + T_2 + \cdots + T_\alpha,$$

where $T_1, T_2, \dots, T_\alpha$ are independent and identically distributed with the common $\Gamma(1, 1)$ -distribution. In the discussion around expression (4.8.2), we have shown how to generate T_i .

Assume then that X has a $\Gamma(\alpha, 1)$ distribution, where α is not an integer. Assume first that $\alpha > 1$. Let Y have a $\Gamma([\alpha], 1/b)$ distribution, where $b < 1$ is chosen later and, as usual, $[\alpha]$ means the greatest integer less than or equal to α . To establish rule (4.8.9), consider the ratio, with $h(x)$ and $t(x)$ proportional to the pdfs of x and y , respectively, given by

$$\frac{h(x)}{t(x)} = b^{-[\alpha]} x^{\alpha - [\alpha]} e^{-(1-b)x}, \quad (4.8.11)$$

where we have ignored some of the normalizing constants. We next determine the constant b .

As Exercise 4.8.14 shows, the derivative of expression (4.8.11) is

$$\frac{d}{dx} b^{-[\alpha]} x^{\alpha - [\alpha]} e^{-(1-b)x} = b^{-[\alpha]} e^{-(1-b)x} [(\alpha - [\alpha]) - x(1-b)] x^{\alpha - [\alpha] - 1}, \quad (4.8.12)$$

which has a maximum critical value at $x = (\alpha - [\alpha])/(1 - b)$. Hence, using the maximum of $h(x)/t(x)$,

$$\frac{h(x)}{t(x)} \leq b^{-[\alpha]} \left[\frac{\alpha - [\alpha]}{(1-b)e} \right]^{\alpha - [\alpha]}. \quad (4.8.13)$$

Now, we need to find our choice of b . Differentiating the right side of this inequality with respect to b , we get, as Exercise 4.8.15 shows,

$$\frac{d}{db} b^{-[\alpha]} (1-b)^{[\alpha]-\alpha} = -b^{-[\alpha]} (1-b)^{[\alpha]-\alpha} \left[\frac{[\alpha] - \alpha b}{b(1-b)} \right], \quad (4.8.14)$$

which has a critical value at $b = [\alpha]/\alpha < 1$. As shown in that exercise, this value of b provides a minimum of the right side of expression (4.8.13). Thus, if we take $b = [\alpha]/\alpha < 1$, then equality (4.8.13) holds and it is the tightest inequality possible and, hence, provides the highest acceptance rate. The final value of M is the right side of expression (4.8.13) evaluated at $b = [\alpha]/\alpha < 1$.

What if $0 < \alpha < 1$? Then the above argument does not work. In this case write $X = YU^{1/\alpha}$ where Y has a $\Gamma(\alpha + 1, 1)$ -distribution, U has a uniform $(0, 1)$ -distribution, and Y and U are independent. Then, as the derivation in Exercise 4.8.16 shows, X has a $\Gamma(\alpha, 1)$ -distribution and we are finished.

For further discussion, see Kennedy and Gentle (1980) and Robert and Casella (1999). ■

EXERCISES

- 4.8.1.** Prove the converse of Theorem MCT. That is, let X be a random variable with a continuous cdf $F(x)$. Assume that $F(x)$ is strictly increasing on the space of X . Consider the random variable $Z = F(X)$. Show that Z has a uniform distribution on the interval $(0, 1)$.

4.8.2. Recall that $\log 2 = \int_0^1 \frac{1}{x+1} dx$. Hence, by using a uniform(0, 1) generator, approximate log 2. Obtain an error of estimation in terms of a large sample 95% confidence interval. Write an R function for the estimate and the error of estimation. Obtain your estimate for 10,000 simulations and compare it to the true value.

4.8.3. Similar to Exercise 4.8.2 but now approximate $\int_0^{1.96} \frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{1}{2}t^2\right\} dt$.

4.8.4. Suppose X is a random variable with the pdf $f_X(x) = b^{-1}f((x - a)/b)$, where $b > 0$. Suppose we can generate observations from $f(z)$. Explain how we can generate observations from $f_X(x)$.

4.8.5. Determine a method to generate random observations for the logistic pdf, (4.4.11). Write an R function that returns a random sample of observations from a logistic distribution. Use your function to generate 10,000 observations from this pdf. Then obtain a histogram (use `hist(x, pr=T)`, where `x` contains the observations). On this histogram overlay a plot of the pdf.

4.8.6. Determine a method to generate random observations for the following pdf:

$$f(x) = \begin{cases} 4x^3 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Write an R function that returns a random sample of observations from this pdf.

4.8.7. Obtain the inverse function of the cdf of the Laplace pdf, given by $f(x) = (1/2)e^{-|x|}$, for $-\infty < x < \infty$. Write an R function that returns a random sample of observations from this distribution.

4.8.8. Determine a method to generate random observations for the extreme-valued pdf that is given by

$$f(x) = \exp\{x - e^x\}, \quad -\infty < x < \infty. \quad (4.8.15)$$

Write an R function that returns a random sample of observations from an extreme-valued distribution. Use your function to generate 10,000 observations from this pdf. Then obtain a histogram (use `hist(x, pr=T)`, where `x` contains the observations). On the histogram overlay a plot of the pdf.

4.8.9. Determine a method to generate random observations for the Cauchy distribution with pdf

$$f(x) = \frac{1}{\pi(1+x^2)}, \quad -\infty < x < \infty. \quad (4.8.16)$$

Write an R function that returns a random sample of observations from this Cauchy distribution.

4.8.10. Suppose we are interested in a particular Weibull distribution with pdf

$$f(x) = \begin{cases} \frac{1}{\theta^3} 3x^2 e^{-x^3/\theta^3} & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Determine a method to generate random observations from this Weibull distribution. Write an R function that returns such a sample.

Hint: Find $F^{-1}(u)$.

4.8.11. Consider the situation in Example 4.8.6 with the hypotheses (4.8.3). Write an algorithm that simulates the power of the test (4.8.4) to detect the alternative $\mu = 0.5$ under the same contaminated normal distribution as in the example. Modify the *R* function `empalphacn(N)` to simulate this power and to obtain an estimate of the error of estimation.

4.8.12. For the last exercise, write an algorithm to simulate the significance level and power to detect the alternative $\mu = 0.5$ for the test (4.8.4) when the underlying distribution is the logistic distribution (4.4.11).

4.8.13. For the proof of Theorem 4.8.1, we assumed that the cdf was strictly increasing over its support. Consider a random variable X with cdf $F(x)$ that is not strictly increasing. Define as the inverse of $F(x)$ the function

$$F^{-1}(u) = \inf\{x : F(x) \geq u\}, \quad 0 < u < 1.$$

Let U have a uniform $(0, 1)$ distribution. Prove that the random variable $F^{-1}(U)$ has cdf $F(x)$.

4.8.14. Verify the derivative in expression (4.8.12) and show that the function (4.8.11) attains a maximum at the critical value $x = (\alpha - [\alpha])/(1 - b)$.

4.8.15. Derive expression (4.8.14) and show that the resulting critical value $b = [\alpha]/\alpha < 1$ gives a minimum of the function that is the right side of expression (4.8.13).

4.8.16. Assume that Y_1 has a $\Gamma(\alpha + 1, 1)$ -distribution, Y_2 has a uniform $(0, 1)$ distribution, and Y_1 and Y_2 are independent. Consider the transformation $X_1 = Y_1 Y_2^{1/\alpha}$ and $X_2 = Y_2$.

(a) Show that the inverse transformation is: $y_1 = x_1/x_2^{1/\alpha}$ and $y_2 = x_2$ with support $0 < x_1 < \infty$ and $0 < x_2 < 1$.

(b) Show that the Jacobian of the transformation is $1/x_2^{1/\alpha}$ and the pdf of (X_1, X_2) is

$$f(x_1, x_2) = \frac{1}{\Gamma(\alpha + 1)} \frac{x_1^\alpha}{x_2} \exp\left\{-\frac{x_1}{x_2^{1/\alpha}}\right\} \frac{1}{x_2^{1/\alpha}}, \quad 0 < x_1 < \infty \text{ and } 0 < x_2 < 1.$$

(c) Show that the marginal distribution of X_1 is $\Gamma(\alpha, 1)$.

4.8.17. Show that the derivative of the ratio in expression (4.8.10) is given by the function $-x \exp\{-x^2/2\}(x^2 - 1)$ with critical values ± 1 . Show that the critical values provide maxima for expression (4.8.10).

4.8.18. Consider the pdf

$$f(x) = \begin{cases} \beta x^{\beta-1} & 0 < x < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

for $\beta > 1$.

- (a) Use Theorem 4.8.1 to generate an observation from this pdf.
- (b) Use the accept-reject algorithm to generate an observation from this pdf.

4.8.19. Proceeding similar to Example 4.8.7, use the accept-reject algorithm to generate an observation from a t distribution with $r > 1$ degrees of freedom when $g(x)$ is the Cauchy pdf.

4.8.20. For $\alpha > 0$ and $\beta > 0$, consider the following accept-reject algorithm:

1. Generate U_1 and U_2 iid uniform(0, 1) random variables. Set $V_1 = U_1^{1/\alpha}$ and $V_2 = U_2^{1/\beta}$.
2. Set $W = V_1 + V_2$. If $W \leq 1$, set $X = V_1/W$; else go to step 1.
3. Deliver X .

Show that X has a beta distribution with parameters α and β , (3.3.9). See Kennedy and Gentle (1980).

4.8.21. Consider the following algorithm:

1. Generate U and V independent uniform $(-1, 1)$ random variables.
2. Set $W = U^2 + V^2$.
3. If $W > 1$ go to step 1.
4. Set $Z = \sqrt{(-2 \log W)/W}$ and let $X_1 = UZ$ and $X_2 = VZ$.

Show that the random variables X_1 and X_2 are iid with a common $N(0, 1)$ distribution. This algorithm was proposed by Marsaglia and Bray (1964).

4.9 Bootstrap Procedures

In the last section, we introduced the method of Monte Carlo and discussed several of its applications. In the last few years, however, Monte Carlo procedures have become increasingly used in statistical inference. In this section, we present the **bootstrap**, one of these procedures. We concentrate on confidence intervals and tests for one- and two-sample problems in this section.

4.9.1 Percentile Bootstrap Confidence Intervals

Let X be a random variable of the continuous type with pdf $f(x; \theta)$, for $\theta \in \Omega$. Suppose $\mathbf{X} = (X_1, X_2, \dots, X_n)$ is a random sample on X and $\hat{\theta} = \hat{\theta}(\mathbf{X})$ is a point estimator of θ . The vector notation, \mathbf{X} , proves useful in this section. In Sections 4.2 and 4.3, we discussed the problem of obtaining confidence intervals for θ in certain situations. In this section, we discuss a general method called the **percentile bootstrap** procedure, which is a *resampling* procedure. It was proposed by Efron (1979).

Informative discussions of such procedures can be found in Efron and Tibshirani (1993) and Davison and Hinkley (1997).

To motivate the procedure, suppose for the moment that

$$\hat{\theta} \text{ has a } N(\theta, \sigma_{\hat{\theta}}^2) \text{ distribution.} \quad (4.9.1)$$

Then as in Section 4.2, a $(1 - \alpha)100\%$ confidence interval for θ is $(\hat{\theta}_L, \hat{\theta}_U)$, where

$$\hat{\theta}_L = \hat{\theta} - z^{(1-\alpha/2)}\sigma_{\hat{\theta}} \quad \text{and} \quad \hat{\theta}_U = \hat{\theta} + z^{(\alpha/2)}\sigma_{\hat{\theta}}, \quad (4.9.2)$$

and $z^{(\gamma)}$ denotes the γ 100th percentile of a standard normal random variable; i.e., $z^{(\gamma)} = \Phi^{-1}(\gamma)$, where Φ is the cdf of a $N(0, 1)$ random variable (see also Exercise 4.9.5). We have gone to a superscript notation here to avoid confusion with the usual subscript notation on critical values.

Now suppose that $\hat{\theta}$ and $\sigma_{\hat{\theta}}$ are realizations from the sample and $\hat{\theta}_L$ and $\hat{\theta}_U$ are calculated as in (4.9.2). Next suppose that $\hat{\theta}^*$ is a random variable with a $N(\hat{\theta}, \sigma_{\hat{\theta}}^2)$ distribution. Then, by (4.9.2),

$$P(\hat{\theta}^* \leq \hat{\theta}_L) = P\left(\frac{\hat{\theta}^* - \hat{\theta}}{\sigma_{\hat{\theta}}} \leq -z^{(1-\alpha/2)}\right) = \alpha/2. \quad (4.9.3)$$

Likewise, $P(\hat{\theta}^* \geq \hat{\theta}_U) = 1 - (\alpha/2)$. Therefore, $\hat{\theta}_L$ and $\hat{\theta}_U$ are the $\frac{\alpha}{2}$ 100th and $(1 - \frac{\alpha}{2})$ 100th percentiles of the distribution of $\hat{\theta}^*$. That is, the percentiles of the $N(\hat{\theta}, \sigma_{\hat{\theta}}^2)$ distribution form the $(1 - \alpha)100\%$ confidence interval for θ .

We want our final procedure to be quite general, so the normality assumption (4.9.1) is definitely not desired and, in Remark 4.9.1, we do show that this assumption is not necessary. So, in general, let $H(t)$ denote the cdf of $\hat{\theta}$.

In practice, though, we do not know the function $H(t)$. Hence the above confidence interval defined by statement (4.9.3) cannot be obtained. But suppose we could take an infinite number of samples $\mathbf{X}_1, \mathbf{X}_2, \dots$; obtain $\hat{\theta}^* = \hat{\theta}(\mathbf{X}^*)$ for each sample \mathbf{X}^* ; and then form the histogram of these estimates $\hat{\theta}^*$. The percentiles of this histogram would be the confidence interval defined by expression (4.9.3). Since we only have one sample, this is impossible. It is, however, the idea behind bootstrap procedures.

Bootstrap procedures simply resample from the empirical distribution defined by the one sample. The sampling is done at random and with replacement and the resamples are all of size n , the size of the original sample. That is, suppose $\mathbf{x}' = (x_1, x_2, \dots, x_n)$ denotes the realization of the sample. Let \hat{F}_n denote the empirical distribution function of the sample. Recall that \hat{F}_n is a discrete cdf that puts mass n^{-1} at each point x_i and that $\hat{F}_n(x)$ is an estimator of $F(x)$. Then a bootstrap sample is a random sample, say $\mathbf{x}'' = (x_1^*, x_2^*, \dots, x_n^*)$, drawn from \hat{F}_n . For example, it follows from the definition of expectation that

$$E(x_i^*) = \sum_{i=1}^n x_i \frac{1}{n} = \frac{1}{n} \sum_{i=1}^n x_i = \bar{x}. \quad (4.9.4)$$

Likewise $V(x_i^*) = n^{-1} \sum_{i=1}^n (x_i - \bar{x})^2$; see Exercise 4.9.2. At first glance, this resampling the sample seems like it would not work. But our only information on sampling variability is within the sample itself, and by resampling the sample we are simulating this variability.

We now give an algorithm that obtains a bootstrap confidence interval. For clarity, we present a formal algorithm, which can be readily coded into languages such as R. Let $\mathbf{x}' = (x_1, x_2, \dots, x_n)$ be the realization of a random sample drawn from a cdf $F(x; \theta)$, $\theta \in \Omega$. Let $\hat{\theta}$ be a point estimator of θ . Let B , an integer, denote the number of bootstrap replications, i.e., the number of resamples. In practice, B is often 3000 or more.

1. Set $j = 1$.
2. While $j \leq B$, do steps 2–5.
3. Let \mathbf{x}_j^* be a random sample of size n drawn from the sample \mathbf{x} . That is, the observations \mathbf{x}_j^* are drawn at random from x_1, x_2, \dots, x_n , with replacement.
4. Let $\hat{\theta}_j^* = \hat{\theta}(\mathbf{x}_j^*)$.
5. Replace j by $j + 1$.
6. Let $\hat{\theta}_{(1)}^* \leq \hat{\theta}_{(2)}^* \leq \dots \leq \hat{\theta}_{(B)}^*$ denote the ordered values of $\hat{\theta}_1^*, \hat{\theta}_2^*, \dots, \hat{\theta}_B^*$. Let $m = [(\alpha/2)B]$, where $[\cdot]$ denotes the greatest integer function. Form the interval

$$(\hat{\theta}_{(m)}^*, \hat{\theta}_{(B+1-m)}^*); \quad (4.9.5)$$

that is, obtain the $\frac{\alpha}{2}100\%$ and $(1 - \frac{\alpha}{2})100\%$ percentiles of the sampling distribution of $\hat{\theta}_1^*, \hat{\theta}_2^*, \dots, \hat{\theta}_B^*$.

The interval in (4.9.5) is called the **percentile bootstrap** confidence interval for θ . In step 6, the subscripted parenthetical notation is a common notation for order statistics (Section 4.4), which is handy in this section.

For the remainder of this subsection, we use as our estimator of θ the sample mean. For the sample mean, the following R function `percentciboot` is an R implementation of this algorithm (it can be downloaded at the site listed in Chapter 1):

```
percentciboot <- function(x,b,alpha){
  theta=mean(x); thetastar=rep(0,b); n=length(x)
  for(i in 1:b){xstar=sample(x,n,replace=T)
  thetastar[i]=mean(xstar)}
  thetastar=sort(thetastar); pick=round((alpha/2)*(b+1))
  lower=thetastar[pick]; upper=thetastar[b-pick+1]
  list(theta=theta,lower=lower,upper=upper)}
  #list(theta=theta,lower=lower,upper=upper,thetasta=thetastar)}
```

The input consists of the sample \mathbf{x} , the number of bootstraps b , and the desired confidence coefficient α . The second line of code computes the mean and the

size of the sample and provides a vector to store the $\hat{\theta}$'s. In the `for` loop, the i th bootstrap sample is obtained by the single command `sample(x,n,replace=T)`, which is followed by the computation of $\hat{\theta}_i^*$. The remainder of the code forms the bootstrap confidence interval, while the `list` command returns the estimate and the bootstrap confidence interval. The optional second `list` command returns the $\hat{\theta}$'s, also. Notice that it is easy to change the code for an estimator other than the mean. For example, to obtain a bootstrap confidence interval for the median just replace the two occurrences of `mean` with `median`. We illustrate this discussion in the next example.

Example 4.9.1. In this example, we sample from a known distribution, but, in practice, the distribution is usually unknown. Let X_1, X_2, \dots, X_n be a random sample from a $\Gamma(1, \beta)$ distribution. Since the mean of this distribution is β , the sample average \bar{X} is an unbiased estimator of β . In this example, the \bar{X} serves as our point estimator of β . The following 20 data points are the realizations (rounded) of a random sample of size $n = 20$ from a $\Gamma(1, 100)$ distribution:

131.7	182.7	73.3	10.7	150.4	42.3	22.2	17.9	264.0	154.4
4.3	265.6	61.9	10.8	48.8	22.5	8.8	150.6	103.0	85.9

The value of \bar{X} for this sample is $\bar{x} = 90.59$, which is our point estimate of β . For illustration, we generated one bootstrap sample of these data. This ordered bootstrap sample is

4.3	4.3	4.3	10.8	10.8	10.8	10.8	17.9	22.5	42.3
48.8	48.8	85.9	131.7	131.7	150.4	154.4	154.4	264.0	265.6

The sample mean of this particular bootstrap sample is $\bar{x}^* = 78.725$. To obtain our bootstrap confidence interval for β , we need to compute many more resamples. For this computation, we used the R function `percentciboot` discussed above. Let `x` denote the R vector of the original sample of observations. We selected 3000 as the number of bootstraps and chose $\alpha = 0.10$. We used the code `percentciboot(x,3000,.10)` to compute our bootstrap confidence interval. Figure 4.9.1 displays a histogram of the 3000 sample means \bar{x}^* 's computed by the code. The sample mean of these 3000 values is 90.13, close to $\bar{x} = 90.59$. Our program also obtained a 90% (bootstrap percentile) confidence interval given by (61.655, 120.48), which the reader can locate on the figure. It does trap the true value $\mu = 100$.

Exercise 4.9.3 shows that if we are sampling from a $\Gamma(1, \beta)$ distribution, then the interval $(2n\bar{x}/[\chi_{2n}^2]^{(1-(\alpha/2))}, 2n\bar{x}/[\chi_{2n}^2]^{(\alpha/2)})$ is an exact $(1 - \alpha)100\%$ confidence interval for β . Note that, in keeping with our superscript notation for critical values, $[\chi_{2n}^2]^{(\gamma)}$ denotes the $\gamma 100\%$ percentile of a χ^2 distribution with $2n$ degrees of freedom. This exact 90% confidence interval for our sample is (64.99, 136.69). ■

What about the validity of a bootstrap confidence interval? Davison and Hinkley (1997) discuss the theory behind the bootstrap in Chapter 2 of their book. Under some general conditions, they show that the bootstrap confidence interval is asymptotically valid.

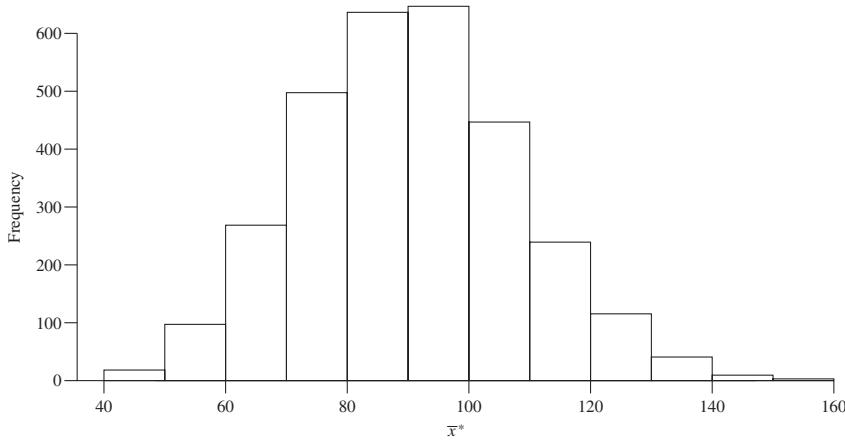

Figure 4.9.1: Histogram of the 3000 bootstrap \bar{x}^* 's. The 90% bootstrap confidence interval is (61.655, 120.48).

One way of improving the bootstrap is to use a pivot random variable, a variable whose distribution is free of other parameters. For instance, in the last example, instead of using \bar{X} , use $\bar{X}/\hat{\sigma}_{\bar{X}}$, where $\hat{\sigma}_{\bar{X}} = S/\sqrt{n}$ and $S = [\sum(X_i - \bar{X})^2/(n-1)]^{1/2}$; that is, adjust \bar{X} by its standard error. This is discussed in Exercise 4.9.6. Other improvements are discussed in the two books cited earlier.

Remark 4.9.1. *Briefly, we show that the normal assumption on the distribution of $\hat{\theta}$, (4.9.1), is transparent to the argument around expression (4.9.3); see Efron and Tibshirani (1993) for further discussion. Suppose H is the cdf of $\hat{\theta}$ and that H depends on θ . Then, using Theorem 4.8.1, we can find an increasing transformation $\phi = m(\theta)$ such that the distribution of $\hat{\phi} = m(\hat{\theta})$ is $N(\phi, \sigma_c^2)$, where $\phi = m(\theta)$ and σ_c^2 is some variance. For example, take the transformation to be $m(\theta) = F_c^{-1}(H(\theta))$, where $F_c(x)$ is the cdf of a $N(\phi, \sigma_c^2)$ distribution. Then, as above, $(\hat{\phi} - z^{(1-\alpha/2)}\sigma_c, \hat{\phi} + z^{(\alpha/2)}\sigma_c)$ is a $(1 - \alpha)100\%$ confidence interval for ϕ . But note that

$$\begin{aligned} 1 - \alpha &= P\left[\hat{\phi} - z^{(1-\alpha/2)}\sigma_c < \phi < \hat{\phi} + z^{(\alpha/2)}\sigma_c\right] \\ &= P\left[m^{-1}(\hat{\phi} - z^{(1-\alpha/2)}\sigma_c) < \theta < m^{-1}(\hat{\phi} + z^{(\alpha/2)}\sigma_c)\right]. \end{aligned} \quad (4.9.6)$$

Hence, $(m^{-1}(\hat{\phi} - z^{(1-\alpha/2)}\sigma_c), m^{-1}(\hat{\phi} + z^{(\alpha/2)}\sigma_c))$ is a $(1 - \alpha)100\%$ confidence interval for θ . Now suppose \hat{H} is the cdf H with a realization $\hat{\theta}$ substituted in for θ , i.e., analogous to the $N(\hat{\theta}, \sigma_{\hat{\theta}}^2)$ distribution above. Suppose $\hat{\theta}^*$ is a random variable with

cdf \hat{H} . Let $\hat{\phi} = m(\hat{\theta})$ and $\hat{\phi}^* = m(\hat{\theta}^*)$. We have

$$\begin{aligned} P\left[\hat{\theta}^* \leq m^{-1}(\hat{\phi} - z^{(1-\alpha/2)}\sigma_c)\right] &= P\left[\hat{\phi}^* \leq \hat{\phi} - z^{(1-\alpha/2)}\sigma_c\right] \\ &= P\left[\frac{\hat{\phi}^* - \hat{\phi}}{\sigma_c} \leq -z^{(1-\alpha/2)}\right] = \alpha/2, \end{aligned}$$

similar to (4.9.3). Therefore, $m^{-1}(\hat{\phi} - z^{(1-\alpha/2)}\sigma_c)$ is the $\frac{\alpha}{2}$ 100th percentile of the cdf \hat{H} . Likewise, $m^{-1}(\hat{\phi} - z^{(\alpha/2)}\sigma_c)$ is the $(1 - \frac{\alpha}{2})$ 100th percentile of the cdf \hat{H} . Therefore, in the general case too, the percentiles of the distribution of \hat{H} form the confidence interval for θ . ■

4.9.2 Bootstrap Testing Procedures

Bootstrap procedures can also be used effectively in testing hypotheses. We begin by discussing these procedures for two-sample problems, which cover many of the nuances of the use of the bootstrap in testing.

Consider a two-sample location problem; that is, $\mathbf{X}' = (X_1, X_2, \dots, X_{n_1})$ is a random sample from a distribution with cdf $F(x)$ and $\mathbf{Y}' = (Y_1, Y_2, \dots, Y_{n_2})$ is a random sample from a distribution with the cdf $F(x - \Delta)$, where $\Delta \in R$. The parameter Δ is the shift in locations between the two samples. Hence Δ can be written as the difference in location parameters. In particular, assuming that the means μ_Y and μ_X exist, we have $\Delta = \mu_Y - \mu_X$. We consider the one-sided hypotheses given by

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0. \quad (4.9.7)$$

As our test statistic, we take the difference in sample means, i.e.,

$$V = \bar{Y} - \bar{X}. \quad (4.9.8)$$

Our decision rule is to reject H_0 if $V \geq c$. As is often done in practice, we base our decision on the p -value of the test. Recall if the samples result in the values x_1, x_2, \dots, x_{n_1} and y_1, y_2, \dots, y_{n_2} with realized sample means \bar{x} and \bar{y} , respectively, then the p -value of the test is

$$\hat{p} = P_{H_0}[V \geq \bar{y} - \bar{x}]. \quad (4.9.9)$$

Our goal is a bootstrap estimate of the p -value. But, unlike the last section, the bootstraps here have to be performed when H_0 is true. An easy way to do this is to combine the samples into one large sample and then to resample at random and with replacement the combined sample into two samples, one of size n_1 (new xs) and one of size n_2 (new ys). Hence the resampling is performed under one distribution; i.e., H_0 is true. Let B be a positive integer and let $v = \bar{y} - \bar{x}$. Our bootstrap algorithm is

1. Combine the samples into one sample: $\mathbf{z}' = (\mathbf{x}', \mathbf{y}')$.
2. Set $j = 1$.

3. While $j \leq B$, do steps 3–6.
4. Obtain a random sample with replacement of size n_1 from \mathbf{z} . Call the sample $\mathbf{x}^{*j} = (x_1^*, x_2^*, \dots, x_{n_1}^*)$. Compute \bar{x}_j^* .
5. Obtain a random sample with replacement of size n_2 from \mathbf{z} . Call the sample $\mathbf{y}^{*j} = (y_1^*, y_2^*, \dots, y_{n_2}^*)$. Compute \bar{y}_j^* .
6. Compute $v_j^* = \bar{y}_j^* - \bar{x}_j^*$.
7. The bootstrap estimated p -value is given by

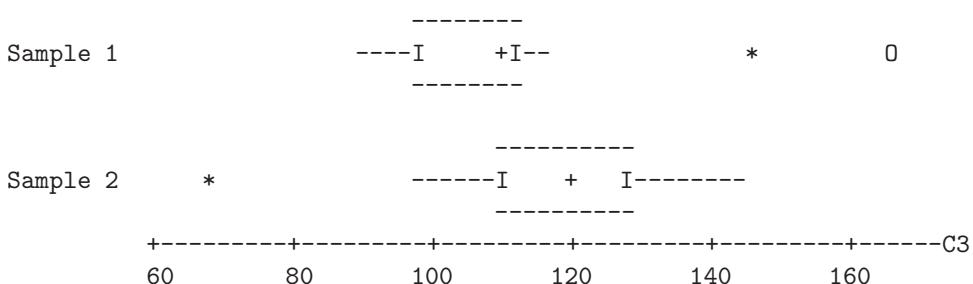

$$\hat{p}^* = \frac{\#\{v_j^* \geq v\}}{B}. \quad (4.9.10)$$

Note that the theory cited above for the bootstrap confidence intervals covers this testing situation also. Hence, this bootstrap p -value is valid.

Example 4.9.2. For illustration, we generated data sets from a contaminated normal distribution, using the R function `rcn`. Let W be a random variable with the contaminated normal distribution (3.4.17) with proportion of contamination $\epsilon = 0.20$ and $\sigma_c = 4$. Thirty independent observations W_1, W_2, \dots, W_{30} were generated from this distribution. Then we let $X_i = 10W_i + 100$ for $1 \leq i \leq 15$ and $Y_i = 10W_{i+15} + 120$ for $1 \leq i \leq 15$. Hence the true shift parameter is $\Delta = 20$. The actual (rounded) data are

X variates								
94.2	111.3	90.0	99.7	116.8	92.2	166.0	95.7	
109.3	106.0	111.7	111.9	111.6	146.4	103.9		
Y variates								
125.5	107.1	67.9	98.2	128.6	123.5	116.5	143.2	
120.3	118.6	105.0	111.8	129.3	130.8	139.8		

Based on the comparison boxplots below, the scales of the two data sets appear to be the same, while the y -variates (Sample 2) appear to be shifted to the right of x -variates (Sample 1).

There are three outliers in the data sets.

Our test statistic for these data is $v = \bar{y} - \bar{x} = 117.74 - 111.11 = 6.63$. Computing with the R function `boottesttwo`, we performed the bootstrap algorithm given above for $B = 3000$ bootstrap replications. The bootstrap p -value was $\hat{p}^* = 0.169$. This means that $(0.169)(3000) = 507$ of the bootstrap test statistics exceeded the value of the test statistic. Furthermore, these bootstrap values were generated under H_0 . In practice, H_0 would generally not be rejected for a p -value this high. In Figure 4.9.2, we display a histogram of the 3000 values of the bootstrap test statistic that were obtained. The relative area to the right of the value of the test statistic, 6.63, is approximately equal to \hat{p}^* .

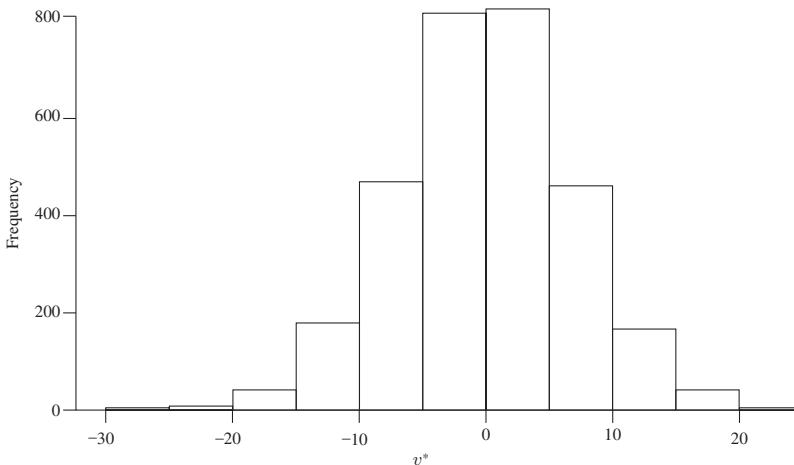

Figure 4.9.2: Histogram of the 3000 bootstrap v^* 's. Locate the value of the test statistic $v = \bar{y} - \bar{x} = 6.63$ on the horizontal axis. The area (proportional to overall area) to the right is the p -value of the bootstrap test.

For comparison purposes, we used the two-sample “pooled” t -test discussed in Example 4.6.2 to test these hypotheses. As the reader can obtain in Exercise 4.9.8, for these data, $t = 0.93$ with a p -value of 0.18, which is quite close to the bootstrap p -value. ■

The above test uses the difference in sample means as the test statistic. Certainly other test statistics could be used. Exercise 4.9.7 asks the reader to obtain the bootstrap test based on the difference in sample medians. Often, as with confidence intervals, standardizing the test statistic by a scale estimator improves the bootstrap test.

The bootstrap test described above for the two-sample problem is analogous to **permutation tests**. In the permutation test, the test statistic is calculated for all possible samples of xs and ys drawn without replacement from the combined data. Often, it is approximated by Monte Carlo methods, in which case it is quite similar to the bootstrap test except, in the case of the bootstrap, the sampling is done with

replacement; see Exercise 4.9.10. Usually, the permutation tests and the bootstrap tests give very similar solutions; see Efron and Tibshirani (1993) for discussion.

As our second testing situation, consider a one-sample location problem. Suppose X_1, X_2, \dots, X_n is a random sample from a continuous cdf $F(x)$ with finite mean μ . Suppose we want to test the hypotheses

$$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu > \mu_0,$$

where μ_0 is specified. As a test statistic we use \bar{X} with the decision rule

Reject H_0 in favor of H_1 if \bar{X} is too large.

Let x_1, x_2, \dots, x_n be the realization of the random sample. We base our decision on the p -value of the test, namely,

$$\hat{p} = P_{H_0}[\bar{X} \geq \bar{x}],$$

where \bar{x} is the realized value of the sample average when the sample is drawn. Our bootstrap test is to obtain a bootstrap estimate of this p -value. At first glance, one might proceed by bootstrapping the statistic \bar{X} . But note that the p -value must be estimated under H_0 . To assure that H_0 is true, bootstrap the values:

$$z_i = x_i - \bar{x} + \mu_0, \quad i = 1, 2, \dots, n. \quad (4.9.11)$$

Our bootstrap procedure is to randomly sample with replacement from z_1, z_2, \dots, z_n . Let $(z_{j,1}^*, \dots, z_{j,n}^*)$ denote, say, the j th bootstrap sample. As in expression (4.9.4), it follows that $E(z_{j,i}^*) = \mu_0$. Hence, using the z_i s, the bootstrap resampling is performed under H_0 . Denote the test statistic by the sample mean \bar{z}_j^* . Then the bootstrap p -value is

$$\hat{p}^* = \frac{\#\{j=1 \mid \bar{z}_j^* \geq \bar{x}\}}{B}. \quad (4.9.12)$$

Example 4.9.3. To illustrate the bootstrap test just described, consider the following data set. We generated $n = 20$ observations $X_i = 10W_i + 100$, where W_i has a contaminated normal distribution with proportion of contamination 20% and $\sigma_c = 4$. Suppose we are interested in testing

$$H_0 : \mu = 90 \text{ versus } H_1 : \mu > 90.$$

Because the true mean of X_i is 100, the null hypothesis is false. The data generated are

$$\begin{array}{cccccccccc} 119.7 & 104.1 & 92.8 & 85.4 & 108.6 & 93.4 & 67.1 & 88.4 & 101.0 & 97.2 \\ 95.4 & 77.2 & 100.0 & 114.2 & 150.3 & 102.3 & 105.8 & 107.5 & 0.9 & 94.1 \end{array}$$

The sample mean of these values is $\bar{x} = 95.27$, which exceeds 90, but is it significantly over 90? As discussed above, we bootstrap the values $z_i = x_i - 95.27 + 90$. The R function `boottestonemean` performs this bootstrap test. For the run we did, it computed the 3000 values \bar{z}_j^* , which are displayed in the histogram in Figure

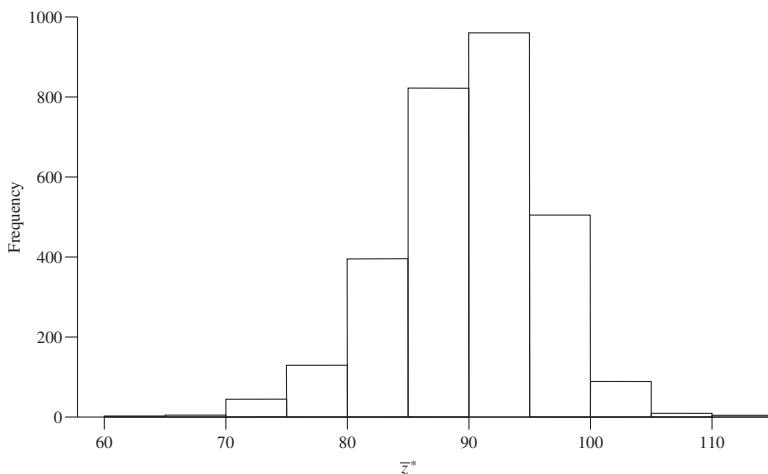

Figure 4.9.3: Histogram of the 3000 bootstrap \bar{z}^* 's discussed in Example 4.9.3. The bootstrap p -value is the area (relative to the total area) under the histogram and to the right of the 95.27.

4.9.3. The mean of these 3000 values is 89.96, which is quite close to 90. Of these 3000 values, 563 exceeded $\bar{x} = 95.27$; hence, the p -value of the bootstrap test is 0.188. The fraction of the total area that is to the right of 95.27 in Figure 4.9.3 is approximately equal to 0.188. Such a high p -value is usually deemed nonsignificant; hence, the null hypothesis would not be rejected.

For comparison, the reader is asked to show in Exercise 4.9.12 that the value of the one-sample t -test is $t = 0.84$, which has a p -value of 0.20. A test based on the median is discussed in Exercise 4.9.13. ■

EXERCISES

4.9.1. Consider the sulfur dioxide concentrations data discussed in Example 4.1.3. Use the R function `percentciboot` to obtain a bootstrap 95% confidence interval for the true mean concentration. Use 3000 bootstraps and compare it with the t -confidence interval for the mean.

4.9.2. Let x_1, x_2, \dots, x_n be the values of a random sample. A bootstrap sample, $\mathbf{x}^* = (x_1^*, x_2^*, \dots, x_n^*)$, is a random sample of x_1, x_2, \dots, x_n drawn with replacement.

- (a) Show that $x_1^*, x_2^*, \dots, x_n^*$ are iid with common cdf \hat{F}_n , the empirical cdf of x_1, x_2, \dots, x_n .
- (b) Show that $E(x_i^*) = \bar{x}$.
- (c) If n is odd, show that median $\{x_i^*\} = x_{((n+1)/2)}$.
- (d) Show that $V(x_i^*) = n^{-1} \sum_{i=1}^n (x_i - \bar{x})^2$.

4.9.3. Let X_1, X_2, \dots, X_n be a random sample from a $\Gamma(1, \beta)$ distribution.

- (a) Show that the confidence interval $(2n\bar{X}/(\chi_{2n}^2)^{(1-(\alpha/2))}, 2n\bar{X}/(\chi_{2n}^2)^{(\alpha/2)})$ is an exact $(1 - \alpha)100\%$ confidence interval for β .
- (b) Using part (a), show that the 90% confidence interval for the data of Example 4.9.1 is (64.99, 136.69).

4.9.4. Consider the situation discussed in Example 4.9.1. Suppose we want to estimate the median of X_i using the sample median.

- (a) Determine the median for a $\Gamma(1, \beta)$ distribution.
- (b) The algorithm for the bootstrap percentile confidence intervals is general and hence can be used for the median. Rewrite the R code in the function `percentciboot.s` so that the median is the estimator. Using the sample given in the example, obtain a 90% bootstrap percentile confidence interval for the median. Did it trap the true median in this case?

4.9.5. Suppose X_1, X_2, \dots, X_n is a random sample drawn from a $N(\mu, \sigma^2)$ distribution. As discussed in Example 4.2.1, the pivot random variable for a confidence interval is

$$t = \frac{\bar{X} - \mu}{S/\sqrt{n}}, \quad (4.9.13)$$

where \bar{X} and S are the sample mean and standard deviation, respectively. Recall by Theorem 3.6.1 that t has a Student t -distribution with $n - 1$ degrees of freedom; hence, its distribution is free of all parameters for this normal situation. In the notation of this section, $t_{n-1}^{(\gamma)}$ denotes the $\gamma100\%$ percentile of a t -distribution with $n - 1$ degrees of freedom. Using this notation, show that a $(1 - \alpha)100\%$ confidence interval for μ is

$$\left(\bar{x} - t^{(1-\alpha/2)} \frac{s}{\sqrt{n}}, \bar{x} - t^{(\alpha/2)} \frac{s}{\sqrt{n}} \right). \quad (4.9.14)$$

4.9.6. Frequently, the bootstrap percentile confidence interval can be improved if the estimator $\hat{\theta}$ is standardized by an estimate of scale. To illustrate this, consider a bootstrap for a confidence interval for the mean. Let $x_1^*, x_2^*, \dots, x_n^*$ be a bootstrap sample drawn from the sample x_1, x_2, \dots, x_n . Consider the bootstrap pivot [analog of (4.9.13)]:

$$t^* = \frac{\bar{x}^* - \bar{x}}{s^*/\sqrt{n}}, \quad (4.9.15)$$

where $\bar{x}^* = n^{-1} \sum_{i=1}^n x_i^*$ and

$$s^{*2} = (n - 1)^{-1} \sum_{i=1}^n (x_i^* - \bar{x}^*)^2.$$

- (a) Rewrite the percentile bootstrap confidence interval algorithm using the mean and collecting t_j^* for $j = 1, 2, \dots, B$. Form the interval

$$\left(\bar{x} - t^{*(1-\alpha/2)} \frac{s}{\sqrt{n}}, \bar{x} - t^{*(\alpha/2)} \frac{s}{\sqrt{n}} \right), \quad (4.9.16)$$

where $t^{*(\gamma)} = t_{(\lceil \gamma * B \rceil)}^*$; that is, order the t_j^* s and pick off the quantiles.

- (b) Rewrite the R program `percentciboot.s` and then use it to find a 90% confidence interval for μ for the data in Example 4.9.3. Use 3000 bootstraps.
(c) Compare your confidence interval in the last part with the nonstandardized bootstrap confidence interval based on the program `percentciboot.s`.

4.9.7. Consider the algorithm for a two-sample bootstrap test given in Section 4.9.2.

- (a) Rewrite the algorithm for the bootstrap test based on the difference in medians.
(b) Consider the data in Example 4.9.2. By substituting the difference in medians for the difference in means in the R program `boottesttwo.s`, obtain the bootstrap test for the algorithm of part (a).
(c) Obtain the estimated p -value of your test for $B = 3000$ and compare it to the estimated p -value of 0.063 that the authors obtained.

4.9.8. Consider the data of Example 4.9.2. The two-sample t -test of Example 4.6.2 can be used to test these hypotheses. The test is not exact here (why?), but it is an approximate test. Show that the value of the test statistic is $t = 0.93$, with an approximate p -value of 0.18.

4.9.9. In Example 4.9.3, suppose we are testing the two-sided hypotheses,

$$H_0 : \mu = 90 \text{ versus } H_1 : \mu \neq 90.$$

- (a) Determine the bootstrap p -value for this situation.
(b) Rewrite the R program `boottestonemean` to obtain this p -value.
(c) Compute the p -value based on 3000 bootstraps.

4.9.10. Consider the following permutation test for the two-sample problem with hypotheses (4.9.7). Let $\mathbf{x}' = (x_1, x_2, \dots, x_{n_1})$ and $\mathbf{y}' = (y_1, y_2, \dots, y_{n_2})$ be the realizations of the two random samples. The test statistic is the difference in sample means $\bar{y} - \bar{x}$. The estimated p -value of the test is calculated as follows:

1. Combine the data into one sample $\mathbf{z}' = (\mathbf{x}', \mathbf{y}')$.
2. Obtain all possible samples of size n_1 drawn without replacement from \mathbf{z} . Each such sample automatically gives another sample of size n_2 , i.e., all elements of \mathbf{z} not in the sample of size n_1 . There are $M = \binom{n_1+n_2}{n_1}$ such samples.

3. For each such sample j :
 - (a) Label the sample of size n_1 by \mathbf{x}^* and label the sample of size n_2 by \mathbf{y}^* .
 - (b) Calculate $v_j^* = \bar{y}^* - \bar{x}^*$.
4. The estimated p -value is $\hat{p}^* = \#\{v_j^* \geq \bar{y} - \bar{x}\}/M$.
 - (a) Suppose we have two samples each of size 3 which result in the realizations: $\mathbf{x}' = (10, 15, 21)$ and $\mathbf{y}' = (20, 25, 30)$. Determine the test statistic and the permutation test described above along with the p -value.
 - (b) If we ignore distinct samples, then we can approximate the permutation test by using the bootstrap algorithm with resampling performed at random and without replacement. Modify the bootstrap program `boottesttwo.s` to do this and obtain this approximate permutation test based on 3000 resamples for the data of Example 4.9.2.
 - (c) In general, what is the probability of having distinct samples in the approximate permutation test described in the last part? Assume that the original data are distinct values.

4.9.11. Let z^* be drawn at random from the discrete distribution that has mass n^{-1} at each point $z_i = x_i - \bar{x} + \mu_0$, where (x_1, x_2, \dots, x_n) is the realization of a random sample. Determine $E(z^*)$ and $V(z^*)$.

4.9.12. For the situation described in Example 4.9.3, show that the value of the one-sample t -test is $t = 0.84$ and its associated p -value is 0.20.

4.9.13. For the situation described in Example 4.9.3, obtain the bootstrap test based on medians. Use the same hypotheses; i.e.,

$$H_0 : \mu = 90 \text{ versus } H_1 : \mu > 90.$$

4.9.14. Consider the Darwin's experiment on *Zea mays* discussed in Examples 4.5.1 and 4.5.5.

- (a) Obtain a bootstrap test for this experimental data. Keep in mind that the data are recorded in pairs. Hence your resampling procedure must keep this dependence intact and still be under H_0 .
- (b) Write an R program that executes your bootstrap test and compare its p -value with that found in Example 4.5.5.

4.10 *Tolerance Limits for Distributions

We propose now to investigate a problem that has something of the same flavor as that treated in Section 4.4. Specifically, can we compute the probability that a certain random interval includes (or *covers*) a preassigned percentage of the probability of the distribution under consideration? And, by appropriate selection of

the random interval, can we be led to an additional distribution-free method of statistical inference?

Let X be a random variable with distribution function $F(x)$ of the continuous type. Let $Z = F(X)$. Then, as shown in Exercise 4.8.1, Z has a uniform(0, 1) distribution. That is, $Z = F(X)$ has the pdf

$$h(z) = \begin{cases} 1 & 0 < z < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Then, if $0 < p < 1$, we have

$$P[F(X) \leq p] = \int_0^p dz = p.$$

Now $F(x) = P(X \leq x)$. Since $P(X = x) = 0$, then $F(x)$ is the fractional part of the probability for the distribution of X that is between $-\infty$ and x . If $F(x) \leq p$, then no more than $100p\%$ of the probability for the distribution of X is between $-\infty$ and x . But recall $P[F(X) \leq p] = p$. That is, the probability that the random variable $Z = F(X)$ is less than or equal to p is precisely the probability that the random interval $(-\infty, X)$ contains no more than $100p\%$ of the probability for the distribution. For example, if $p = 0.70$, the probability that the random interval $(-\infty, X)$ contains no more than 70% of the probability for the distribution is 0.70; and the probability that the random interval $(-\infty, X)$ contains more than 70% of the probability for the distribution is $1 - 0.70 = 0.30$.

We now consider certain functions of the order statistics. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution that has a positive and continuous pdf $f(x)$ if and only if $a < x < b$, and let $F(x)$ denote the associated distribution function. Consider the random variables $F(X_1), F(X_2), \dots, F(X_n)$. These random variables are independent and each, in accordance with Exercise 4.8.1, has a uniform distribution on the interval $(0, 1)$. Thus, $F(X_1), F(X_2), \dots, F(X_n)$ is a random sample of size n from a uniform distribution on the interval $(0, 1)$. Consider the order statistics of this random sample $F(X_1), F(X_2), \dots, F(X_n)$. Let Z_1 be the smallest of these $F(X_i)$, Z_2 the next $F(X_i)$ in order of magnitude, \dots , and Z_n the largest of $F(X_i)$. If Y_1, Y_2, \dots, Y_n are the order statistics of the initial random sample X_1, X_2, \dots, X_n , the fact that $F(x)$ is a nondecreasing (here, strictly increasing) function of x implies that $Z_1 = F(Y_1), Z_2 = F(Y_2), \dots, Z_n = F(Y_n)$. Hence, it follows from (4.4.1) that the joint pdf of Z_1, Z_2, \dots, Z_n is given by

$$h(z_1, z_2, \dots, z_n) = \begin{cases} n! & 0 < z_1 < z_2 < \dots < z_n < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (4.10.1)$$

This proves a special case of the following theorem.

Theorem 4.10.1. *Let Y_1, Y_2, \dots, Y_n denote the order statistics of a random sample of size n from a distribution of the continuous type that has pdf $f(x)$ and cdf $F(x)$. The joint pdf of the random variables $Z_i = F(Y_i)$, $i = 1, 2, \dots, n$, is given by expression (4.10.1).*

Because the distribution function of $Z = F(X)$ is given by z , $0 < z < 1$, it follows from (4.4.2) that the marginal pdf of $Z_k = F(Y_k)$ is the following beta pdf:

$$h_k(z_k) = \begin{cases} \frac{n!}{(k-1)!(n-k)!} z_k^{k-1} (1-z_k)^{n-k} & 0 < z_k < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (4.10.2)$$

Moreover, from (4.4.3), the joint pdf of $Z_i = F(Y_i)$ and $Z_j = F(Y_j)$ is, with $i < j$, given by

$$h(z_i, z_j) = \begin{cases} \frac{n! z_i^{i-1} (z_j - z_i)^{j-i-1} (1-z_j)^{n-j}}{(i-1)!(j-i-1)!(n-j)!} & 0 < z_i < z_j < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (4.10.3)$$

Consider the difference $Z_j - Z_i = F(Y_j) - F(Y_i)$, $i < j$. Now $F(y_j) = P(X \leq y_j)$ and $F(y_i) = P(X \leq y_i)$. Since $P(X = y_i) = P(X = y_j) = 0$, then the difference $F(y_j) - F(y_i)$ is that fractional part of the probability for the distribution of X that is between y_i and y_j . Let p denote a positive proper fraction. If $F(y_j) - F(y_i) \geq p$, then at least $100p\%$ of the probability for the distribution of X is between y_i and y_j . Let it be given that $\gamma = P[F(Y_j) - F(Y_i) \geq p]$. Then the random interval (Y_i, Y_j) has probability γ of containing at least $100p\%$ of the probability for the distribution of X . Now if y_i and y_j denote, respectively, observational values of Y_i and Y_j , the interval (y_i, y_j) either does or does not contain at least $100p\%$ of the probability for the distribution of X . However, we refer to the interval (y_i, y_j) as a **$100\gamma\%$ tolerance interval** for $100p\%$ of the probability for the distribution of X . In like vein, y_i and y_j are called the $100\gamma\%$ *tolerance limits* for $100p\%$ of the probability for the distribution of X .

One way to compute the probability $\gamma = P[F(Y_j) - F(Y_i) \geq p]$ is to use equation (4.10.3), which gives the joint pdf of $Z_i = F(Y_i)$ and $Z_j = F(Y_j)$. The required probability is then given by

$$\gamma = P(Z_j - Z_i \geq p) = \int_0^{1-p} \left[\int_{p+z_i}^1 h_{ij}(z_i, z_j) dz_j \right] dz_i.$$

Sometimes, this is a rather tedious computation. For this reason and also for the reason that *coverages* are important in distribution-free statistical inference, we choose to introduce at this time the concept of coverage.

Consider the random variables $W_1 = F(Y_1) = Z_1$, $W_2 = F(Y_2) - F(Y_1) = Z_2 - Z_1$, and $W_3 = F(Y_3) - F(Y_2) = Z_3 - Z_2, \dots, W_n = F(Y_n) - F(Y_{n-1}) = Z_n - Z_{n-1}$. The random variable W_1 is called a *coverage* of the random interval $\{x : -\infty < x < Y_1\}$ and the random variable W_i , $i = 2, 3, \dots, n$, is called a *coverage* of the random interval $\{x : Y_{i-1} < x < Y_i\}$. We find that the joint pdf of the n coverages W_1, W_2, \dots, W_n . First we note that the inverse functions of the associated transformation are given by

$$z_i = \sum_{j=1}^i w_j, \quad \text{for } i = 1, 2, \dots, n.$$

We also note that the Jacobian is equal to 1 and that the space of positive probability density is

$$\{(w_1, w_2, \dots, w_n) : 0 < w_i, i = 1, 2, \dots, n, w_1 + \dots + w_n < 1\}.$$

Since the joint pdf of Z_1, Z_2, \dots, Z_n is $n!$, $0 < z_1 < z_2 < \dots < z_n < 1$, zero elsewhere, the joint pdf of the n coverages is

$$k(w_1, \dots, w_n) = \begin{cases} n! & 0 < w_i, i = 1, \dots, n, w_1 + \dots + w_n < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Because the pdf $k(w_1, \dots, w_n)$ is symmetric in w_1, w_2, \dots, w_n , it is evident that the distribution of every sum of r , $r < n$, of these coverages W_1, \dots, W_n is exactly the same for each fixed value of r . For instance, if $i < j$ and $r = j - i$, the distribution of $Z_j - Z_i = F(Y_j) - F(Y_i) = W_{i+1} + W_{i+2} + \dots + W_j$ is exactly the same as that of $Z_{j-i} = F(Y_{j-i}) = W_1 + W_2 + \dots + W_{j-i}$. But we know that the pdf of Z_{j-i} is the beta pdf of the form

$$h_{j-i}(v) = \begin{cases} \frac{\Gamma(n+1)}{\Gamma(j-i)\Gamma(n-j+i+1)} v^{j-i-1} (1-v)^{n-j+i} & 0 < v < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Consequently, $F(Y_j) - F(Y_i)$ has this pdf and

$$P[F(Y_j) - F(Y_i) \geq p] = \int_p^1 h_{j-i}(v) dv.$$

Example 4.10.1. Let $Y_1 < Y_2 < \dots < Y_6$ be the order statistics of a random sample of size 6 from a distribution of the continuous type. We want to use the observed interval (y_1, y_6) as a tolerance interval for 80% of the distribution. Then

$$\begin{aligned} \gamma &= P[F(Y_6) - F(Y_1) \geq 0.8] \\ &= 1 - \int_0^{0.8} 30v^4(1-v) dv, \end{aligned}$$

because the integrand is the pdf of $F(Y_6) - F(Y_1)$. Accordingly,

$$\gamma = 1 - 6(0.8)^5 + 5(0.8)^6 = 0.34,$$

approximately. That is, the observed values of Y_1 and Y_6 define a 34% tolerance interval for 80% the probability for the distribution. ■

Remark 4.10.1. Tolerance intervals are extremely important and often they are more desirable than confidence intervals. For illustration, consider a “fill” problem in which a manufacturer says that each container has at least 12 ounces of the product. Let X be the amount in a container. The company would be pleased to note that the interval $(12.1, 12.3)$, for instance, is a 95% tolerance interval for 99% of the distribution of X . This would be true in this case, because the FDA allows a very small fraction of the containers to be less than 12 ounces. ■

EXERCISES

4.10.1. Let Y_1 and Y_n be, respectively, the first and the n th order statistic of a random sample of size n from a distribution of the continuous type having cdf $F(x)$. Find the smallest value of n such that $P[F(Y_n) - F(Y_1) \geq 0.5]$ is at least 0.95.

4.10.2. Let Y_2 and Y_{n-1} denote the second and the $(n-1)$ st order statistics of a random sample of size n from a distribution of the continuous type having a distribution function $F(x)$. Compute $P[F(Y_{n-1}) - F(Y_2) \geq p]$, where $0 < p < 1$.

4.10.3. Let $Y_1 < Y_2 < \dots < Y_{48}$ be the order statistics of a random sample of size 48 from a distribution of the continuous type. We want to use the observed interval (y_4, y_{45}) as a $100\gamma\%$ tolerance interval for 75% of the distribution.

- (a) What is the value of γ ?
- (b) Approximate the integral in part (a) by noting that it can be written as a partial sum of a binomial pdf, which in turn can be approximated by probabilities associated with a normal distribution (see Section 5.3).

4.10.4. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from a distribution of the continuous type having distribution function $F(x)$.

- (a) What is the distribution of $U = 1 - F(Y_j)$?
- (b) Determine the distribution of $V = F(Y_n) - F(Y_j) + F(Y_i) - F(Y_1)$, where $i < j$.

4.10.5. Let $Y_1 < Y_2 < \dots < Y_{10}$ be the order statistics of a random sample from a continuous-type distribution with distribution function $F(x)$. What is the joint distribution of $V_1 = F(Y_4) - F(Y_2)$ and $V_2 = F(Y_{10}) - F(Y_6)$?

Chapter 5

Consistency and Limiting Distributions

In Chapter 4, we introduced some of the main concepts in statistical inference, namely, point estimation, confidence intervals, and hypothesis tests. For readers who on first reading have skipped Chapter 4, we review these ideas in Section 5.1.1.

The theory behind these inference procedures often depends on the distribution of a pivot random variable. For example, suppose X_1, X_2, \dots, X_n is a random sample on a random variable X which has a $N(\mu, \sigma^2)$ distribution. Denote the sample mean by $\bar{X}_n = n^{-1} \sum_{i=1}^n X_i$. Then the pivot random variable of interest is

$$Z_n = \frac{\bar{X}_n - \mu}{\sigma/\sqrt{n}}.$$

This random variable plays a key role in obtaining exact procedures for the confidence interval for μ and for tests of hypotheses concerning μ . What if X does not have a normal distribution? In this case, in Chapter 4, we discussed inference procedures, which were quite similar to the exact procedures, but they were based on the “approximate” (as the sample size n gets large) distribution of Z_n .

There are several types of convergence used in statistics, and in this chapter we discuss two of the most important: convergence in probability and convergence in distribution. These concepts provide structure to the “approximations” discussed in Chapter 4. Beyond this, though, these concepts play a crucial role in much of statistics and probability. We begin with convergence in probability.

5.1 Convergence in Probability

In this section, we formalize a way of saying that a sequence of random variables $\{X_n\}$ is getting “close” to another random variable X , as $n \rightarrow \infty$. We will use this concept throughout the book.

Definition 5.1.1. Let $\{X_n\}$ be a sequence of random variables and let X be a random variable defined on a sample space. We say that X_n converges in probability to X if, for all $\epsilon > 0$,

$$\lim_{n \rightarrow \infty} P[|X_n - X| \geq \epsilon] = 0,$$

or equivalently,

$$\lim_{n \rightarrow \infty} P[|X_n - X| < \epsilon] = 1.$$

If so, we write

$$X_n \xrightarrow{P} X.$$

If $X_n \xrightarrow{P} X$, we often say that the mass of the difference $X_n - X$ is converging to 0. In statistics, often the limiting random variable X is a constant; i.e., X is a degenerate random variable with all its mass at some constant a . In this case, we write $X_n \xrightarrow{P} a$. Also, as Exercise 5.1.1 shows, for a sequence of real numbers $\{a_n\}$, $a_n \rightarrow a$ is equivalent to $a_n \xrightarrow{P} a$.

One way of showing convergence in probability is to use Chebyshev's Theorem (1.10.3). An illustration of this is given in the following proof. To emphasize the fact that we are working with sequences of random variables, we may place a subscript n on the appropriate random variables; for example, write \bar{X} as \bar{X}_n .

Theorem 5.1.1 (Weak Law of Large Numbers). Let $\{X_n\}$ be a sequence of iid random variables having common mean μ and variance $\sigma^2 < \infty$. Let $\bar{X}_n = n^{-1} \sum_{i=1}^n X_i$. Then

$$\bar{X}_n \xrightarrow{P} \mu.$$

Proof. From expression (2.8.6) of Example 2.8.1, the mean and variance of \bar{X}_n are μ and σ^2/n , respectively. Hence, by Chebyshev's Theorem, we have for every $\epsilon > 0$,

$$P[|\bar{X}_n - \mu| \geq \epsilon] = P[|\bar{X}_n - \mu| \geq (\epsilon\sqrt{n}/\sigma)(\sigma/\sqrt{n})] \leq \frac{\sigma^2}{n\epsilon^2} \rightarrow 0. \blacksquare$$

This theorem says that all the mass of the distribution of \bar{X}_n is converging to μ , as $n \rightarrow \infty$. In a sense, for n large, \bar{X}_n is close to μ . But how close? For instance, if we were to estimate μ by \bar{X}_n , what can we say about the error of estimation? We answer this in Section 5.3.

Actually, in a more advanced course, a Strong Law of Large Numbers is proved; see page 124 of Chung (1974). One result of this theorem is that we can weaken the hypothesis of Theorem 5.1.1 to the assumption that the random variables X_i are independent and each has finite mean μ . Thus the Strong Law of Large Numbers is a first moment theorem, while the Weak Law requires the existence of the second moment.

There are several theorems concerning convergence in probability which will be useful in the sequel. Together the next two theorems say that convergence in probability is closed under linearity.

Theorem 5.1.2. Suppose $X_n \xrightarrow{P} X$ and $Y_n \xrightarrow{P} Y$. Then $X_n + Y_n \xrightarrow{P} X + Y$.

Proof: Let $\epsilon > 0$ be given. Using the triangle inequality, we can write

$$|X_n - X| + |Y_n - Y| \geq |(X_n + Y_n) - (X + Y)| \geq \epsilon.$$

Since P is monotone relative to set containment, we have

$$\begin{aligned} P[|(X_n + Y_n) - (X + Y)| \geq \epsilon] &\leq P[|X_n - X| + |Y_n - Y| \geq \epsilon] \\ &\leq P[|X_n - X| \geq \epsilon/2] + P[|Y_n - Y| \geq \epsilon/2]. \end{aligned}$$

By the hypothesis of the theorem, the last two terms converge to 0 as $n \rightarrow \infty$, which gives us the desired result. ■

Theorem 5.1.3. Suppose $X_n \xrightarrow{P} X$ and a is a constant. Then $aX_n \xrightarrow{P} aX$.

Proof: If $a = 0$, the result is immediate. Suppose $a \neq 0$. Let $\epsilon > 0$. The result follows from these equalities:

$$P[|aX_n - aX| \geq \epsilon] = P[|a||X_n - X| \geq \epsilon] = P[|X_n - X| \geq \epsilon/|a|],$$

and by hypotheses the last term goes to 0 as $n \rightarrow \infty$ ■

Theorem 5.1.4. Suppose $X_n \xrightarrow{P} a$ and the real function g is continuous at a . Then $g(X_n) \xrightarrow{P} g(a)$.

Proof: Let $\epsilon > 0$. Then since g is continuous at a , there exists a $\delta > 0$ such that if $|x - a| < \delta$, then $|g(x) - g(a)| < \epsilon$. Thus

$$|g(x) - g(a)| \geq \epsilon \Rightarrow |x - a| \geq \delta.$$

Substituting X_n for x in the above implication, we obtain

$$P[|g(X_n) - g(a)| \geq \epsilon] \leq P[|X_n - a| \geq \delta].$$

By the hypothesis, the last term goes to 0 as $n \rightarrow \infty$, which gives us the result. ■

This theorem gives us many useful results. For instance, if $X_n \xrightarrow{P} a$, then

$$\begin{aligned} X_n^2 &\xrightarrow{P} a^2 \\ 1/X_n &\xrightarrow{P} 1/a, \quad \text{provided } a \neq 0 \\ \sqrt{X_n} &\xrightarrow{P} \sqrt{a}, \quad \text{provided } a \geq 0. \end{aligned}$$

Actually, in a more advanced class, it is shown that if $X_n \xrightarrow{P} X$ and g is a continuous function, then $g(X_n) \xrightarrow{P} g(X)$; see page 104 of Tucker (1967). We make use of this in the next theorem.

Theorem 5.1.5. Suppose $X_n \xrightarrow{P} X$ and $Y_n \xrightarrow{P} Y$. Then $X_n Y_n \xrightarrow{P} XY$.

Proof: Using the above results, we have

$$\begin{aligned} X_n Y_n &= \frac{1}{2} X_n^2 + \frac{1}{2} Y_n^2 - \frac{1}{2} (X_n - Y_n)^2 \\ &\xrightarrow{P} \frac{1}{2} X^2 + \frac{1}{2} Y^2 - \frac{1}{2} (X - Y)^2 = XY. \blacksquare \end{aligned}$$

5.1.1 Sampling and Statistics

Consider the situation where we have a random variable X whose pdf (or pmf) is written as $f(x; \theta)$ for an unknown parameter $\theta \in \Omega$. For example, the distribution of X is normal with unknown mean μ and variance σ^2 . Then $\theta = (\mu, \sigma^2)$ and $\Omega = \{\theta = (\mu, \sigma^2) : -\infty < \mu < \infty, \sigma > 0\}$. As another example, the distribution of X is $\Gamma(1, \beta)$, where $\beta > 0$ is unknown. Our information consists of a **random sample** X_1, X_2, \dots, X_n on X ; i.e., X_1, X_2, \dots, X_n are independent and identically distributed (iid) random variables with the common pdf $f(x; \theta)$, $\theta \in \Omega$. We say that T is a **statistic** if T is a function of the sample; i.e., $T = T(X_1, X_2, \dots, X_n)$. Here, we want to consider T as a **point estimator** of θ . For example, if μ is the unknown mean of X , then we may use as our point estimator the sample mean $\bar{X} = n^{-1} \sum_{i=1}^n X_i$. When the sample is drawn let x_1, x_2, \dots, x_n denote the observed values of X_1, X_2, \dots, X_n . We call these values the **realized** values of the sample and call the realized statistic $t = t(x_1, x_2, \dots, x_n)$ a **point estimate** of θ .

In Chapters 6 and 7, we discuss properties of point estimators in formal settings. For now, we consider two properties: **unbiasedness** and **consistency**. We say that the point estimator T for θ is **unbiased** if $E(T) = \theta$. Recall in Section 2.8, we showed that the sample mean \bar{X} and the sample variance S^2 are unbiased estimators of μ and σ^2 respectively; see equations (2.8.6) and (2.8.8). We next consider consistency of a point estimator.

Definition 5.1.2 (Consistency). *Let X be a random variable with cdf $F(x, \theta)$, $\theta \in \Omega$. Let X_1, \dots, X_n be a sample from the distribution of X and let T_n denote a statistic. We say T_n is a **consistent** estimator of θ if*

$$T_n \xrightarrow{P} \theta.$$

If X_1, \dots, X_n is a random sample from a distribution with finite mean μ and variance σ^2 , then by the Weak Law of Large Numbers, the sample mean, \bar{X}_n , is a consistent estimator of μ .

Figure 5.1.1 displays realizations of the sample mean for samples of size 10 to 2000 in steps of 10 which are drawn from a $N(0, 1)$ distribution. The lines on the plot encompass the interval $\mu \pm 0.04$ for $\mu = 0$. As n increases, the realizations tend to stay within this interval, verifying the consistency of the sample mean. The R function `consistmean` produces this plot. Within this function, if the function `mean` is changed to `median` a similar plot on the estimator `med` X_i can be obtained.

Example 5.1.1 (Sample Variance). Let X_1, \dots, X_n denote a random sample from a distribution with mean μ and variance σ^2 . In Example 2.8.7, we showed that the

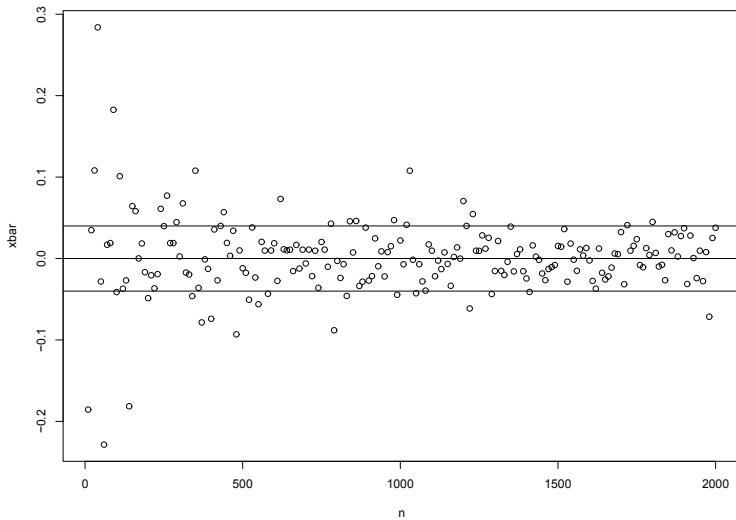

Figure 5.1.1: Realizations of the point estimator \bar{X} for samples of size 10 to 2000 in steps of 10 which are drawn from a $N(0, 1)$ distribution.

sample variance is an unbiased estimator of σ^2 . We now show that it is a consistent estimator of σ^2 . Recall Theorem 5.1.1 which shows that $\bar{X}_n \xrightarrow{P} \mu$. To show that the sample variance converges in probability to σ^2 , assume further that $E[X_1^4] < \infty$, so that $\text{Var}(S^2) < \infty$. Using the preceding results, we can show the following:

$$\begin{aligned} S_n^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X}_n)^2 &= \frac{n}{n-1} \left(\frac{1}{n} \sum_{i=1}^n X_i^2 - \bar{X}_n^2 \right) \\ &\xrightarrow{P} 1 \cdot [E(X_1^2) - \mu^2] = \sigma^2. \end{aligned}$$

Hence the sample variance is a consistent estimator of σ^2 . From the discussion above, we have immediately that $S_n \xrightarrow{P} \sigma$; that is, the sample standard deviation is a consistent estimator of the population standard deviation. ■

Unlike the last example, sometimes we can obtain the convergence by using the distribution function. We illustrate this with the following example:

Example 5.1.2 (Maximum of a Sample from a Uniform Distribution). Suppose X_1, \dots, X_n is a random sample from a uniform($0, \theta$) distribution. Suppose θ is unknown. An intuitive estimate of θ is the maximum of the sample. Let $Y_n = \max\{X_1, \dots, X_n\}$. Exercise 5.1.4 shows that the cdf of Y_n is

$$F_{Y_n}(t) = \begin{cases} 1 & t > \theta \\ \left(\frac{t}{\theta}\right)^n & 0 < t \leq \theta \\ 0 & t \leq 0. \end{cases} \quad (5.1.1)$$

Hence the pdf of Y_n is

$$f_{Y_n}(t) = \begin{cases} \frac{n}{\theta^n} t^{n-1} & 0 < t \leq \theta \\ 0 & \text{elsewhere.} \end{cases} \quad (5.1.2)$$

Based on its pdf, it is easy to show that $E(Y_n) = (n/(n+1))\theta$. Thus, Y_n is a biased estimator of θ . Note, however, that $((n+1)/n)Y_n$ is an unbiased estimator of θ . Further, based on the cdf of Y_n , it is easily seen that $Y_n \xrightarrow{P} \theta$ and, hence, that the sample maximum is a consistent estimate of θ . Note that the unbiased estimator, $((n+1)/n)Y_n$, is also consistent. ■

To expand on Example 5.1.2, by the Weak Law of Large Numbers, Theorem 5.1.1, it follows that \bar{X}_n is a consistent estimator of $\theta/2$, so $2\bar{X}_n$ is a consistent estimator of θ . Note the difference in how we showed that Y_n and $2\bar{X}_n$ converge to θ in probability. For Y_n we used the cdf of Y_n , but for $2\bar{X}_n$ we appealed to the Weak Law of Large Numbers. In fact, the cdf of $2\bar{X}_n$ is quite complicated for the uniform model. In many situations, the cdf of the statistic cannot be obtained, but we can appeal to asymptotic theory to establish the result. There are other estimators of θ . Which is the “best” estimator? In future chapters we will be concerned with such questions.

Consistency is a very important property for an estimator to have. It is a poor estimator that does not approach its target as the sample size gets large. Note that the same cannot be said for the property of unbiasedness. For example, instead of using the sample variance to estimate σ^2 , suppose we use $V = n^{-1} \sum_{i=1}^n (X_i - \bar{X})^2$. Then V is consistent for σ^2 , but it is biased, because $E(V) = (n-1)\sigma^2/n$. Thus the bias of V is $-\sigma^2/n$, which vanishes as $n \rightarrow \infty$.

EXERCISES

5.1.1. Let $\{a_n\}$ be a sequence of real numbers. Hence, we can also say that $\{a_n\}$ is a sequence of constant (degenerate) random variables. Let a be a real number. Show that $a_n \rightarrow a$ is equivalent to $a_n \xrightarrow{P} a$.

5.1.2. Let the random variable Y_n have a distribution that is $b(n, p)$.

- (a) Prove that Y_n/n converges in probability to p . This result is one form of the weak law of large numbers.
- (b) Prove that $1 - Y_n/n$ converges in probability to $1 - p$.
- (c) Prove that $(Y_n/n)(1 - Y_n/n)$ converges in probability to $p(1 - p)$.

5.1.3. Let W_n denote a random variable with mean μ and variance b/n^p , where $p > 0$, μ , and b are constants (not functions of n). Prove that W_n converges in probability to μ .

Hint: Use Chebyshev’s inequality.

5.1.4. Derive the cdf given in expression (5.1.1).

5.1.5. Consider the R function `consistmean` which produces the plot shown in Figure 5.1.1. Obtain a similar plot for the sample median when the distribution sampled is the $N(0, 1)$ distribution. Compare the mean and median plots.

5.1.6. Write an R function that obtains a plot similar to Figure 5.1.1 for the situation described in Example 5.1.2. For the plot choose $\theta = 10$.

5.1.7. Let X_1, \dots, X_n be iid random variables with common pdf

$$f(x) = \begin{cases} e^{-(x-\theta)} & x > \theta, -\infty < \theta < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (5.1.3)$$

This pdf is called the **shifted exponential**. Let $Y_n = \min\{X_1, \dots, X_n\}$. Prove that $Y_n \rightarrow \theta$ in probability by first obtaining the cdf of Y_n .

5.1.8. Using the assumptions behind the confidence interval given in expression (4.2.9), show that

$$\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}} / \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} \xrightarrow{P} 1.$$

5.1.9. For Exercise 5.1.7, obtain the mean of Y_n . Is Y_n an unbiased estimator of θ ? Obtain an unbiased estimator of θ based on Y_n .

5.2 Convergence in Distribution

In the last section, we introduced the concept of convergence in probability. With this concept, we can formally say, for instance, that a statistic converges to a parameter and, furthermore, in many situations we can show this without having to obtain the distribution function of the statistic. But how close is the statistic to the estimator? For instance, can we obtain the error of estimation with some credence? The method of convergence discussed in this section, in conjunction with earlier results, gives us affirmative answers to these questions.

Definition 5.2.1 (Convergence in Distribution). *Let $\{X_n\}$ be a sequence of random variables and let X be a random variable. Let F_{X_n} and F_X be, respectively, the cdfs of X_n and X . Let $C(F_X)$ denote the set of all points where F_X is continuous. We say that X_n converges in distribution to X if*

$$\lim_{n \rightarrow \infty} F_{X_n}(x) = F_X(x), \quad \text{for all } x \in C(F_X).$$

We denote this convergence by

$$X_n \xrightarrow{D} X.$$

Remark 5.2.1. This material on convergence in probability and in distribution comes under what statisticians and probabilists refer to as *asymptotic theory*. Often, we say that the distribution of X is the **asymptotic distribution** or the **limiting distribution** of the sequence $\{X_n\}$. We might even refer informally to

the asymptotics of certain situations. Moreover, for illustration, instead of saying $X_n \xrightarrow{D} X$, where X has a standard normal distribution, we may write

$$X_n \xrightarrow{D} N(0, 1)$$

as an abbreviated way of saying the same thing. Clearly, the right-hand member of this last expression is a distribution and not a random variable as it should be, but we will make use of this convention. In addition, we may say that X_n has a *limiting* standard normal distribution to mean that $X_n \xrightarrow{D} X$, where X has a standard normal random, or equivalently $X_n \xrightarrow{D} N(0, 1)$. ■

Motivation for considering only points of continuity of F_X is given by the following simple example. Let X_n be a random variable with all its mass at $\frac{1}{n}$ and let X be a random variable with all its mass at 0. Then, as Figure 5.2.1 shows, all the mass of X_n is converging to 0, i.e., the distribution of X . At the point of discontinuity of F_X , $\lim F_{X_n}(0) = 0 \neq 1 = F_X(0)$, while at continuity points x of F_X (i.e., $x \neq 0$), $\lim F_{X_n}(x) = F_X(x)$. Hence, according to the definition, $X_n \xrightarrow{D} X$.

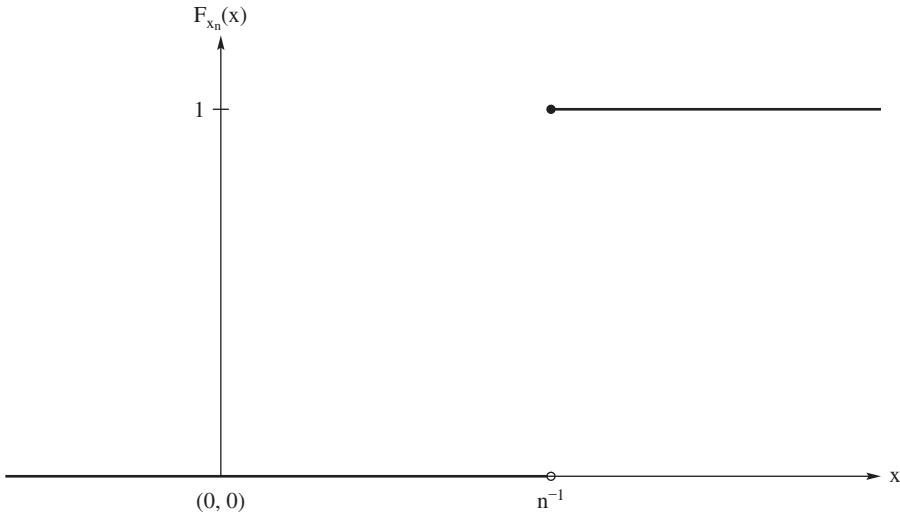

Figure 5.2.1: Cdf of X_n , that has all its mass at n^{-1} .

Convergence in probability is a way of saying that a sequence of random variables X_n is getting close to another random variable X . On the other hand, convergence in distribution is only concerned with the cdfs F_{X_n} and F_X . A simple example illustrates this. Let X be a continuous random variable with a pdf $f_X(x)$ that is symmetric about 0; i.e., $f_X(-x) = f_X(x)$. Then it is easy to show that the density of the random variable $-X$ is also $f_X(x)$. Thus, X and $-X$ have the same distributions. Define the sequence of random variables X_n as

$$X_n = \begin{cases} X & \text{if } n \text{ is odd} \\ -X & \text{if } n \text{ is even.} \end{cases} \quad (5.2.1)$$

Clearly, $F_{X_n}(x) = F_X(x)$ for all x in the support of X , so that $X_n \xrightarrow{D} X$. On the other hand, the sequence X_n does not get close to X . In particular, $X_n \not\rightarrow X$ in probability.

Example 5.2.1. Let \bar{X}_n have the cdf

$$F_n(\bar{x}) = \int_{-\infty}^{\bar{x}} \frac{1}{\sqrt{1/n}\sqrt{2\pi}} e^{-nw^2/2} dw.$$

If the change of variable $v = \sqrt{n}w$ is made, we have

$$F_n(\bar{x}) = \int_{-\infty}^{\sqrt{n}\bar{x}} \frac{1}{\sqrt{2\pi}} e^{-v^2/2} dv.$$

It is clear that

$$\lim_{n \rightarrow \infty} F_n(\bar{x}) = \begin{cases} 0 & \bar{x} < 0 \\ \frac{1}{2} & \bar{x} = 0 \\ 1 & \bar{x} > 0. \end{cases}$$

Now the function

$$F(\bar{x}) = \begin{cases} 0 & \bar{x} < 0 \\ 1 & \bar{x} \geq 0 \end{cases}$$

is a cdf and $\lim_{n \rightarrow \infty} F_n(\bar{x}) = F(\bar{x})$ at every point of continuity of $F(\bar{x})$. To be sure, $\lim_{n \rightarrow \infty} F_n(0) \neq F(0)$, but $F(\bar{x})$ is not continuous at $\bar{x} = 0$. Accordingly, the sequence $\bar{X}_1, \bar{X}_2, \bar{X}_3, \dots$ converges in distribution to a random variable that has a degenerate distribution at $\bar{x} = 0$. ■

Example 5.2.2. Even if a sequence X_1, X_2, X_3, \dots converges in distribution to a random variable X , we cannot in general determine the distribution of X by taking the limit of the pmf of X_n . This is illustrated by letting X_n have the pmf

$$p_n(x) = \begin{cases} 1 & x = 2 + n^{-1} \\ 0 & \text{elsewhere.} \end{cases}$$

Clearly, $\lim_{n \rightarrow \infty} p_n(x) = 0$ for all values of x . This may suggest that X_n , for $n = 1, 2, 3, \dots$, does not converge in distribution. However, the cdf of X_n is

$$F_n(x) = \begin{cases} 0 & x < 2 + n^{-1} \\ 1 & x \geq 2 + n^{-1}, \end{cases}$$

and

$$\lim_{n \rightarrow \infty} F_n(x) = \begin{cases} 0 & x \leq 2 \\ 1 & x > 2. \end{cases}$$

Since

$$F(x) = \begin{cases} 0 & x < 2 \\ 1 & x \geq 2 \end{cases}$$

is a cdf, and since $\lim_{n \rightarrow \infty} F_n(x) = F(x)$ at all points of continuity of $F(x)$, the sequence X_1, X_2, X_3, \dots converges in distribution to a random variable with cdf $F(x)$. ■

The last example shows in general that we cannot determine limiting distributions by considering pmfs or pdfs. But under certain conditions we can determine convergence in distribution by considering the sequence of pdfs as the following example shows.

Example 5.2.3. Let T_n have a t -distribution with n degrees of freedom, $n = 1, 2, 3, \dots$. Thus its cdf is

$$F_n(t) = \int_{-\infty}^t \frac{\Gamma[(n+1)/2]}{\sqrt{\pi n} \Gamma(n/2)} \frac{1}{(1+y^2/n)^{(n+1)/2}} dy,$$

where the integrand is the pdf $f_n(y)$ of T_n . Accordingly,

$$\lim_{n \rightarrow \infty} F_n(t) = \lim_{n \rightarrow \infty} \int_{-\infty}^t f_n(y) dy = \int_{-\infty}^t \lim_{n \rightarrow \infty} f_n(y) dy,$$

by a result in analysis (the Lebesgue Dominated Convergence Theorem) that allows us to interchange the order of the limit and integration, provided that $|f_n(y)|$ is dominated by a function that is integrable. This is true because

$$|f_n(y)| \leq 10f_1(y)$$

and

$$\int_{-\infty}^t 10f_1(y) dy = \frac{10}{\pi} \arctan t < \infty,$$

for all real t . Hence we can find the limiting distribution by finding the limit of the pdf of T_n . It is

$$\begin{aligned} \lim_{n \rightarrow \infty} f_n(y) &= \lim_{n \rightarrow \infty} \left\{ \frac{\Gamma[(n+1)/2]}{\sqrt{n/2} \Gamma(n/2)} \right\} \lim_{n \rightarrow \infty} \left\{ \frac{1}{(1+y^2/n)^{1/2}} \right\} \\ &\quad \times \lim_{n \rightarrow \infty} \left\{ \frac{1}{\sqrt{2\pi}} \left[\left(1 + \frac{y^2}{n} \right) \right]^{-n/2} \right\}. \end{aligned}$$

Using the fact from elementary calculus that

$$\lim_{n \rightarrow \infty} \left(1 + \frac{y^2}{n} \right)^n = e^{y^2},$$

the limit associated with the third factor is clearly the pdf of the standard normal distribution. The second limit obviously equals 1. By Remark 5.2.2, the first limit also equals 1. Thus, we have

$$\lim_{n \rightarrow \infty} F_n(t) = \int_{-\infty}^t \frac{1}{\sqrt{2\pi}} e^{-y^2/2} dy,$$

and hence T_n has a limiting standard normal distribution. ■

Remark 5.2.2 (Stirling's Formula). In advanced calculus the following approximation is derived:

$$\Gamma(k+1) \approx \sqrt{2\pi}k^{k+1/2}e^{-k}. \quad (5.2.2)$$

This is known as *Stirling's formula* and it is an excellent approximation when k is large. Because $\Gamma(k+1) = k!$, for k an integer, this formula gives an idea of how fast $k!$ grows. As Exercise 5.2.21 shows, this approximation can be used to show that the first limit in Example 5.2.3 is 1. ■

Example 5.2.4 (Maximum of a Sample from a Uniform Distribution, Continued). Recall Example 5.1.2, where X_1, \dots, X_n is a random sample from a uniform($0, \theta$) distribution. Again, let $Y_n = \max\{X_1, \dots, X_n\}$, but now consider the random variable $Z_n = n(\theta - Y_n)$. Let $t \in (0, n\theta)$. Then, using the cdf of Y_n , (5.1.1), the cdf of Z_n is

$$\begin{aligned} P[Z_n \leq t] &= P[Y_n \geq \theta - (t/n)] \\ &= 1 - \left(\frac{\theta - (t/n)}{\theta} \right)^n \\ &= 1 - \left(1 - \frac{t/\theta}{n} \right)^n \\ &\rightarrow 1 - e^{-t/\theta}. \end{aligned}$$

Note that the last quantity is the cdf of an exponential random variable with mean θ , (3.3.6), i.e., $\Gamma(1, \theta)$. So we say that $Z_n \xrightarrow{D} Z$, where Z is distributed $\Gamma(1, \theta)$. ■

Remark 5.2.3. To simplify several of the proofs of this section, we make use of the $\underline{\lim}$ and $\overline{\lim}$ of a sequence. For readers who are unfamiliar with these concepts, we discuss them in Appendix A. In this brief remark, we highlight the properties needed for understanding the proofs. Let $\{a_n\}$ be a sequence of real numbers and define the two subsequences

$$b_n = \sup\{a_n, a_{n+1}, \dots\}, \quad n = 1, 2, 3, \dots, \quad (5.2.3)$$

$$c_n = \inf\{a_n, a_{n+1}, \dots\}, \quad n = 1, 2, 3, \dots. \quad (5.2.4)$$

The sequences $\{b_n\}$ and $\{c_n\}$ are nonincreasing and nondecreasing, respectively. Hence their limits always exist (may be $\pm\infty$) and are denoted respectively by $\overline{\lim}_{n \rightarrow \infty} a_n$ and $\underline{\lim}_{n \rightarrow \infty} a_n$. Further, $c_n \leq a_n \leq b_n$, for all n . Hence, by the Sandwich Theorem (see Theorem A.2.1 of Appendix A), if $\underline{\lim}_{n \rightarrow \infty} a_n = \overline{\lim}_{n \rightarrow \infty} a_n$, then $\lim_{n \rightarrow \infty} a_n$ exists and is given by $\lim_{n \rightarrow \infty} a_n = \underline{\lim}_{n \rightarrow \infty} a_n$.

As discussed in Appendix A, several other properties of these concepts are useful. For example, suppose $\{p_n\}$ is a sequence of probabilities and $\overline{\lim}_{n \rightarrow \infty} p_n = 0$. Then, by the Sandwich Theorem, since $0 \leq p_n \leq \sup\{p_n, p_{n+1}, \dots\}$ for all n , we have $\overline{\lim}_{n \rightarrow \infty} p_n = 0$. Also, for any two sequences $\{a_n\}$ and $\{b_n\}$, it easily follows that $\overline{\lim}_{n \rightarrow \infty} (a_n + b_n) \leq \overline{\lim}_{n \rightarrow \infty} a_n + \overline{\lim}_{n \rightarrow \infty} b_n$. ■

As the following theorem shows, convergence in distribution is weaker than convergence in probability. Thus convergence in distribution is often called weak convergence.

Theorem 5.2.1. *If X_n converges to X in probability, then X_n converges to X in distribution.*

Proof: Let x be a point of continuity of $F_X(x)$. For every $\epsilon > 0$,

$$\begin{aligned} F_{X_n}(x) &= P[X_n \leq x] \\ &= P[\{X_n \leq x\} \cap \{|X_n - X| < \epsilon\}] + P[\{X_n \leq x\} \cap \{|X_n - X| \geq \epsilon\}] \\ &\leq P[X \leq x + \epsilon] + P[|X_n - X| \geq \epsilon]. \end{aligned}$$

Based on this inequality and the fact that $X_n \xrightarrow{P} X$, we see that

$$\overline{\lim}_{n \rightarrow \infty} F_{X_n}(x) \leq F_X(x + \epsilon). \quad (5.2.5)$$

To get a lower bound, we proceed similarly with the complement to show that

$$P[X_n > x] \leq P[X \geq x - \epsilon] + P[|X_n - X| \geq \epsilon].$$

Hence

$$\underline{\lim}_{n \rightarrow \infty} F_{X_n}(x) \geq F_X(x - \epsilon). \quad (5.2.6)$$

Using a relationship between $\overline{\lim}$ and $\underline{\lim}$, it follows from (5.2.5) and (5.2.6) that

$$F_X(x - \epsilon) \leq \underline{\lim}_{n \rightarrow \infty} F_{X_n}(x) \leq \overline{\lim}_{n \rightarrow \infty} F_{X_n}(x) \leq F_X(x + \epsilon).$$

Letting $\epsilon \downarrow 0$ gives us the desired result. ■

Reconsider the sequence of random variables $\{X_n\}$ defined by expression (5.2.1).

Here, $X_n \xrightarrow{D} X$ but $X_n \not\xrightarrow{P} X$. So, in general, the converse of the above theorem is not true. However, it is true if X is degenerate, as shown by the following theorem.

Theorem 5.2.2. *If X_n converges to the constant b in distribution, then X_n converges to b in probability.*

Proof: Let $\epsilon > 0$ be given. Then

$$\lim_{n \rightarrow \infty} P[|X_n - b| \leq \epsilon] = \lim_{n \rightarrow \infty} F_{X_n}(b + \epsilon) - \lim_{n \rightarrow \infty} F_{X_n}[(b - \epsilon) - 0] = 1 - 0 = 1,$$

which is the desired result. ■

A result that will prove quite useful is the following:

Theorem 5.2.3. *Suppose X_n converges to X in distribution and Y_n converges in probability to 0. Then $X_n + Y_n$ converges to X in distribution.*

The proof is similar to that of Theorem 5.2.2 and is left to Exercise 5.2.13. We often use this last result as follows. Suppose it is difficult to show that X_n converges to X in distribution, but it is easy to show that Y_n converges in distribution to X and that $X_n - Y_n$ converges to 0 in probability. Hence, by this last theorem, $X_n = Y_n + (X_n - Y_n) \xrightarrow{D} X$, as desired.

The next two theorems state general results. A proof of the first result can be found in a more advanced text, while the second, Slutsky's Theorem, follows similarly to that of Theorem 5.2.1.

Theorem 5.2.4. Suppose X_n converges to X in distribution and g is a continuous function on the support of X . Then $g(X_n)$ converges to $g(X)$ in distribution.

An often-used application of this theorem occurs when we have a sequence of random variables Z_n which converges in distribution to a standard normal random variable Z . Because the distribution of Z^2 is $\chi^2(1)$, it follows by Theorem 5.2.4 that Z_n^2 converges in distribution to a $\chi^2(1)$ distribution.

Theorem 5.2.5 (Slutsky's Theorem). Let X_n , X , A_n , and B_n be random variables and let a and b be constants. If $X_n \xrightarrow{D} X$, $A_n \xrightarrow{P} a$, and $B_n \xrightarrow{P} b$, then

$$A_n + B_n X_n \xrightarrow{D} a + bX.$$

5.2.1 Bounded in Probability

Another useful concept, related to convergence in distribution, is boundedness in probability of a sequence of random variables.

First consider any random variable X with cdf $F_X(x)$. Then given $\epsilon > 0$, we can bound X in the following way. Because the lower limit of F_X is 0 and its upper limit is 1, we can find η_1 and η_2 such that

$$F_X(x) < \epsilon/2 \text{ for } x \leq \eta_1 \text{ and } F_X(x) > 1 - (\epsilon/2) \text{ for } x \geq \eta_2.$$

Let $\eta = \max\{|\eta_1|, |\eta_2|\}$. Then

$$P[|X| \leq \eta] = F_X(\eta) - F_X(-\eta) \geq 1 - (\epsilon/2) - (\epsilon/2) = 1 - \epsilon. \quad (5.2.7)$$

Thus random variables which are not bounded [e.g., X is $N(0, 1)$] are still bounded in this probability way. This is a useful concept for sequences of random variables, which we define next.

Definition 5.2.2 (Bounded in Probability). We say that the sequence of random variables $\{X_n\}$ is bounded in probability if, for all $\epsilon > 0$, there exist a constant $B_\epsilon > 0$ and an integer N_ϵ such that

$$n \geq N_\epsilon \Rightarrow P[|X_n| \leq B_\epsilon] \geq 1 - \epsilon.$$

Next, consider a sequence of random variables $\{X_n\}$ which converges in distribution to a random variable X that has cdf F . Let $\epsilon > 0$ be given and choose η so that (5.2.7) holds for X . We can always choose η so that η and $-\eta$ are continuity points of F . We then have

$$\lim_{n \rightarrow \infty} P[|X_n| \leq \eta] \geq \lim_{n \rightarrow \infty} F_{X_n}(\eta) - \lim_{n \rightarrow \infty} F_{X_n}(-\eta) = F_X(\eta) - F_X(-\eta) \geq 1 - \epsilon.$$

To be precise, we can then choose N so large that $P[|X_n| \leq \eta] \geq 1 - \epsilon$, for $n \geq N$. We have thus proved the following theorem

Theorem 5.2.6. Let $\{X_n\}$ be a sequence of random variables and let X be a random variable. If $X_n \rightarrow X$ in distribution, then $\{X_n\}$ is bounded in probability.

As the following example shows, the converse of this theorem is not true.

Example 5.2.5. Take $\{X_n\}$ to be the following sequence of degenerate random variables. For $n = 2m$ even, $X_{2m} = 2 + (1/(2m))$ with probability 1. For $n = 2m - 1$ odd, $X_{2m-1} = 1 + (1/(2m))$ with probability 1. Then the sequence $\{X_2, X_4, X_6, \dots\}$ converges in distribution to the degenerate random variable $Y = 2$, while the sequence $\{X_1, X_3, X_5, \dots\}$ converges in distribution to the degenerate random variable $W = 1$. Since the distributions of Y and W are not the same, the sequence $\{X_n\}$ does not converge in distribution. Because all of the mass of the sequence $\{X_n\}$ is in the interval $[1, 5/2]$, however, the sequence $\{X_n\}$ is bounded in probability. ■

One way of thinking of a sequence that is bounded in probability (or one that is converging to a random variable in distribution) is that the probability mass of $|X_n|$ is not escaping to ∞ . At times we can use boundedness in probability instead of convergence in distribution. A property we will need later is given in the following theorem:

Theorem 5.2.7. *Let $\{X_n\}$ be a sequence of random variables bounded in probability and let $\{Y_n\}$ be a sequence of random variables that converges to 0 in probability. Then*

$$X_n Y_n \xrightarrow{P} 0.$$

Proof: Let $\epsilon > 0$ be given. Choose $B_\epsilon > 0$ and an integer N_ϵ such that

$$n \geq N_\epsilon \Rightarrow P[|X_n| \leq B_\epsilon] \geq 1 - \epsilon.$$

Then

$$\begin{aligned} \overline{\lim}_{n \rightarrow \infty} P[|X_n Y_n| \geq \epsilon] &\leq \overline{\lim}_{n \rightarrow \infty} P[|X_n Y_n| \geq \epsilon, |X_n| \leq B_\epsilon] \\ &\quad + \overline{\lim}_{n \rightarrow \infty} P[|X_n Y_n| \geq \epsilon, |X_n| > B_\epsilon] \\ &\leq \overline{\lim}_{n \rightarrow \infty} P[|Y_n| \geq \epsilon/B_\epsilon] + \epsilon = \epsilon, \end{aligned} \tag{5.2.8}$$

from which the desired result follows. ■

5.2.2 Δ -Method

Recall a common problem discussed in the last three chapters is the situation where we know the distribution of a random variable, but we want to determine the distribution of a function of it. This is also true in asymptotic theory, and Theorems 5.2.4 and 5.2.5 are illustrations of this. Another such result is called the **Δ -method**. To establish this result, we need a convenient form of the mean value theorem with remainder, sometimes called Young's Theorem; see Hardy (1992) or Lehmann (1999). Suppose $g(x)$ is differentiable at x . Then we can write

$$g(y) = g(x) + g'(x)(y - x) + o(|y - x|), \tag{5.2.9}$$

where the notation o means

$$a = o(b) \text{ if and only if } \frac{a}{b} \rightarrow 0, \text{ as } b \rightarrow 0.$$

The *little-o* notation is used in terms of convergence in probability, also. We often write $o_p(X_n)$, which means

$$Y_n = o_p(X_n) \text{ if and only if } \frac{Y_n}{X_n} \xrightarrow{P} 0, \text{ as } n \rightarrow \infty. \quad (5.2.10)$$

There is a corresponding *big-O_p* notation, which is given by

$$Y_n = O_p(X_n) \text{ if and only if } \frac{Y_n}{X_n} \text{ is bounded in probability as } n \rightarrow \infty. \quad (5.2.11)$$

The following theorem illustrates the little-o notation, but it also serves as a lemma for Theorem 5.2.9.

Theorem 5.2.8. *Suppose $\{Y_n\}$ is a sequence of random variables that is bounded in probability. Suppose $X_n = o_p(Y_n)$. Then $X_n \xrightarrow{P} 0$, as $n \rightarrow \infty$.*

Proof: Let $\epsilon > 0$ be given. Because the sequence $\{Y_n\}$ is bounded in probability, there exist positive constants N_ϵ and B_ϵ such that

$$n \geq N_\epsilon \implies P[|Y_n| \leq B_\epsilon] \geq 1 - \epsilon. \quad (5.2.12)$$

Also, because $X_n = o_p(Y_n)$, we have

$$\frac{X_n}{Y_n} \xrightarrow{P} 0, \quad (5.2.13)$$

as $n \rightarrow \infty$. We then have

$$\begin{aligned} P[|X_n| \geq \epsilon] &= P[|X_n| \geq \epsilon, |Y_n| \leq B_\epsilon] + P[|X_n| \geq \epsilon, |Y_n| > B_\epsilon] \\ &\leq P\left[\frac{|X_n|}{|Y_n|} \geq \frac{\epsilon}{B_\epsilon}\right] + P[|Y_n| > B_\epsilon]. \end{aligned}$$

By (5.2.13) and (5.2.12), respectively, the first and second terms on the right side can be made arbitrarily small by choosing n sufficiently large. Hence the result is true. ■

We can now prove the theorem about the asymptotic procedure, which is often called the Δ method.

Theorem 5.2.9. *Let $\{X_n\}$ be a sequence of random variables such that*

$$\sqrt{n}(X_n - \theta) \xrightarrow{D} N(0, \sigma^2). \quad (5.2.14)$$

Suppose the function $g(x)$ is differentiable at θ and $g'(\theta) \neq 0$. Then

$$\sqrt{n}(g(X_n) - g(\theta)) \xrightarrow{D} N(0, \sigma^2(g'(\theta))^2). \quad (5.2.15)$$

Proof: Using expression (5.2.9), we have

$$g(X_n) = g(\theta) + g'(\theta)(X_n - \theta) + o_p(|X_n - \theta|),$$

where o_p is interpreted as in (5.2.10). Rearranging, we have

$$\sqrt{n}(g(X_n) - g(\theta)) = g'(\theta)\sqrt{n}(X_n - \theta) + o_p(\sqrt{n}|X_n - \theta|).$$

Because (5.2.14) holds, Theorem 5.2.6 implies that $\sqrt{n}|X_n - \theta|$ is bounded in probability. Therefore, by Theorem 5.2.8, $o_p(\sqrt{n}|X_n - \theta|) \rightarrow 0$, in probability. Hence, by (5.2.14) and Theorem 5.2.1, the result follows. ■

Illustrations of the Δ -method can be found in Example 5.2.8 and the exercises.

5.2.3 Moment Generating Function Technique

To find the limiting distribution function of a random variable X_n by using the definition obviously requires that we know $F_{X_n}(x)$ for each positive integer n . But it is often difficult to obtain $F_{X_n}(x)$ in closed form. Fortunately, if it exists, the mgf that corresponds to the cdf $F_{X_n}(x)$ often provides a convenient method of determining the limiting cdf.

The following theorem, which is essentially Curtiss' (1942) modification of a theorem of Lévy and Cramér, explains how the mgf may be used in problems of limiting distributions. A proof of the theorem is beyond the scope of this book. It can readily be found in more advanced books; see, for instance, page 171 of Breiman (1968) for a proof based on characteristic functions.

Theorem 5.2.10. *Let $\{X_n\}$ be a sequence of random variables with mgf $M_{X_n}(t)$ that exists for $-h < t < h$ for all n . Let X be a random variable with mgf $M(t)$, which exists for $|t| \leq h_1 \leq h$. If $\lim_{n \rightarrow \infty} M_{X_n}(t) = M(t)$ for $|t| \leq h_1$, then $X_n \xrightarrow{D} X$.*

In this and the subsequent sections are several illustrations of the use of Theorem 5.2.10. In some of these examples it is convenient to use a certain limit that is established in some courses in advanced calculus. We refer to a limit of the form

$$\lim_{n \rightarrow \infty} \left[1 + \frac{b}{n} + \frac{\psi(n)}{n} \right]^{cn},$$

where b and c do not depend upon n and where $\lim_{n \rightarrow \infty} \psi(n) = 0$. Then

$$\lim_{n \rightarrow \infty} \left[1 + \frac{b}{n} + \frac{\psi(n)}{n} \right]^{cn} = \lim_{n \rightarrow \infty} \left(1 + \frac{b}{n} \right)^{cn} = e^{bc}. \quad (5.2.16)$$

For example,

$$\lim_{n \rightarrow \infty} \left(1 - \frac{t^2}{n} + \frac{t^2}{n^{3/2}} \right)^{-n/2} = \lim_{n \rightarrow \infty} \left(1 - \frac{t^2}{n} + \frac{t^2/\sqrt{n}}{n} \right)^{-n/2}.$$

Here $b = -t^2$, $c = -\frac{1}{2}$, and $\psi(n) = t^2/\sqrt{n}$. Accordingly, for every fixed value of t , the limit is $e^{t^2/2}$.

Example 5.2.6. Let Y_n have a distribution that is $b(n, p)$. Suppose that the mean $\mu = np$ is the same for every n ; that is, $p = \mu/n$, where μ is a constant. We shall find the limiting distribution of the binomial distribution, when $p = \mu/n$, by finding the limit of $M_{Y_n}(t)$. Now

$$M_{Y_n}(t) = E(e^{tY_n}) = [(1-p) + pe^t]^n = \left[1 + \frac{\mu(e^t - 1)}{n}\right]^n$$

for all real values of t . Hence we have

$$\lim_{n \rightarrow \infty} M_{Y_n}(t) = e^{\mu(e^t - 1)}$$

for all real values of t . Since there exists a distribution, namely the Poisson distribution with mean μ , that has mgf $e^{\mu(e^t - 1)}$, then, in accordance with the theorem and under the conditions stated, it is seen that Y_n has a limiting Poisson distribution with mean μ .

Whenever a random variable has a limiting distribution, we may, if we wish, use the limiting distribution as an approximation to the exact distribution function. The result of this example enables us to use the Poisson distribution as an approximation to the binomial distribution when n is large and p is small. To illustrate the use of the approximation, let Y have a binomial distribution with $n = 50$ and $p = \frac{1}{25}$. Then, using R for the calculations, we have

$$Pr(Y \leq 1) = \left(\frac{24}{25}\right)^{50} + 50\left(\frac{1}{25}\right) = \text{pbinom}(1, 50, 1/25) = 0.4004812$$

approximately. Since $\mu = np = 2$, the Poisson approximation to this probability is

$$e^{-2} + 2e^{-2} = \text{ppois}(1, 2) = 0.4060058. \blacksquare$$

Example 5.2.7. Let Z_n be $\chi^2(n)$. Then the mgf of Z_n is $(1-2t)^{-n/2}$, $t < \frac{1}{2}$. The mean and the variance of Z_n are, respectively, n and $2n$. The limiting distribution of the random variable $Y_n = (Z_n - n)/\sqrt{2n}$ will be investigated. Now the mgf of Y_n is

$$\begin{aligned} M_{Y_n}(t) &= E\left\{\exp\left[t\left(\frac{Z_n - n}{\sqrt{2n}}\right)\right]\right\} \\ &= e^{-tn/\sqrt{2n}} E(e^{tZ_n/\sqrt{2n}}) \\ &= \exp\left[-\left(t\sqrt{\frac{2}{n}}\right)\left(\frac{n}{2}\right)\right] \left(1 - 2\frac{t}{\sqrt{2n}}\right)^{-n/2}, \quad t < \frac{\sqrt{2n}}{2}. \end{aligned}$$

This may be written in the form

$$M_{Y_n}(t) = \left(e^{t\sqrt{2/n}} - t\sqrt{\frac{2}{n}}e^{t\sqrt{2/n}}\right)^{-n/2}, \quad t < \sqrt{\frac{n}{2}}.$$

In accordance with Taylor's formula, there exists a number $\xi(n)$, between 0 and $t\sqrt{2/n}$, such that

$$e^{t\sqrt{2/n}} = 1 + t\sqrt{\frac{2}{n}} + \frac{1}{2} \left(t\sqrt{\frac{2}{n}}\right)^2 + \frac{e^{\xi(n)}}{6} \left(t\sqrt{\frac{2}{n}}\right)^3.$$

If this sum is substituted for $e^{t\sqrt{2/n}}$ in the last expression for $M_{Y_n}(t)$, it is seen that

$$M_{Y_n}(t) = \left(1 - \frac{t^2}{n} + \frac{\psi(n)}{n}\right)^{-n/2},$$

where

$$\psi(n) = \frac{\sqrt{2}t^3 e^{\xi(n)}}{3\sqrt{n}} - \frac{\sqrt{2}t^3}{\sqrt{n}} - \frac{2t^4 e^{\xi(n)}}{3n}.$$

Since $\xi(n) \rightarrow 0$ as $n \rightarrow \infty$, then $\lim \psi(n) = 0$ for every fixed value of t . In accordance with the limit proposition cited earlier in this section, we have

$$\lim_{n \rightarrow \infty} M_{Y_n}(t) = e^{t^2/2}$$

for all real values of t . That is, the random variable $Y_n = (Z_n - n)/\sqrt{2n}$ has a limiting standard normal distribution.

Figure 5.2.2 displays a verification of the asymptotic distribution of the standardized Z_n . For each value of $n = 5, 10, 20$ and 50 , 1000 observations from a $\chi^2(n)$ -distribution were generated, using the R command `rchisq(1000, n)`. Each observation z_n was standardized as $y_n = (z_n - n)/\sqrt{2n}$ and a histogram of these y_n s was computed. On this histogram, the pdf of a standard normal distribution is superimposed. Note that at $n = 5$, the histogram of y_n values is skewed, but as n increases, the shape of the histogram nears the shape of the pdf, verifying the above theory. These plots are computed by the R function `cdisplt`. In this function, it is easy to change values of n for further such plots. ■

Example 5.2.8 (Example 5.2.7, Continued). In the notation of the last example, we showed that

$$\sqrt{n} \left[\frac{1}{\sqrt{2n}} Z_n - \frac{1}{\sqrt{2}} \right] \xrightarrow{D} N(0, 1). \quad (5.2.17)$$

For this situation, though, there are times when we are interested in the square root of Z_n . Let $g(t) = \sqrt{t}$ and let $W_n = g(Z_n/(\sqrt{2n})) = (Z_n/(\sqrt{2n}))^{1/2}$. Note that $g(1/\sqrt{2}) = 1/2^{1/4}$ and $g'(1/\sqrt{2}) = 2^{-3/4}$. Therefore, by the Δ -method, Theorem 5.2.9, and (5.2.17), we have

$$\sqrt{n} \left[W_n - 1/2^{1/4} \right] \xrightarrow{D} N(0, 2^{-3/2}). \quad \blacksquare \quad (5.2.18)$$

EXERCISES

5.2.1. Let \bar{X}_n denote the mean of a random sample of size n from a distribution that is $N(\mu, \sigma^2)$. Find the limiting distribution of \bar{X}_n .

5.2.2. Let Y_1 denote the minimum of a random sample of size n from a distribution that has pdf $f(x) = e^{-(x-\theta)}$, $\theta < x < \infty$, zero elsewhere. Let $Z_n = n(Y_1 - \theta)$. Investigate the limiting distribution of Z_n .

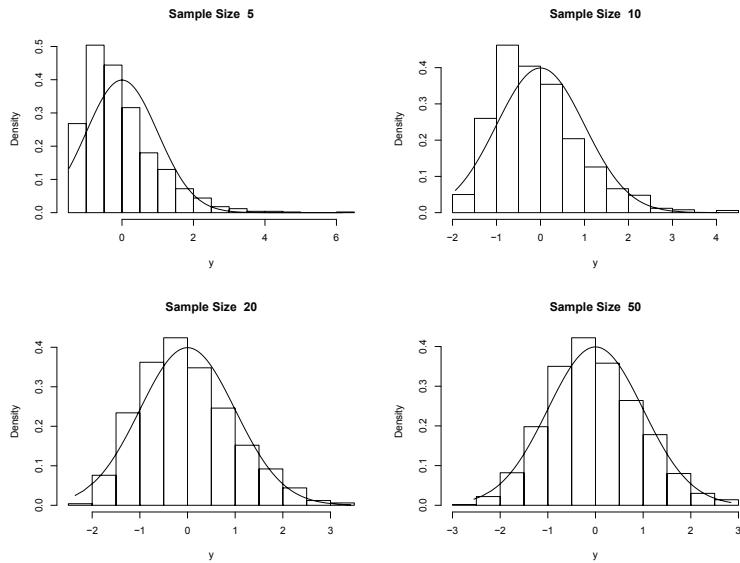

Figure 5.2.2: For each value of n , a histogram plot of 1000 generated values y_n is shown, where y_n is discussed in Example 5.2.7. The limiting $N(0, 1)$ pdf is superimposed on the histogram.

5.2.3. Let Y_n denote the maximum of a random sample of size n from a distribution of the continuous type that has cdf $F(x)$ and pdf $f(x) = F'(x)$. Find the limiting distribution of $Z_n = n[1 - F(Y_n)]$.

5.2.4. Let Y_2 denote the second smallest item of a random sample of size n from a distribution of the continuous type that has cdf $F(x)$ and pdf $f(x) = F'(x)$. Find the limiting distribution of $W_n = nF(Y_2)$.

5.2.5. Let the pmf of Y_n be $p_n(y) = 1$, $y = n$, zero elsewhere. Show that Y_n does not have a limiting distribution. (In this case, the probability has “escaped” to infinity.)

5.2.6. Let X_1, X_2, \dots, X_n be a random sample of size n from a distribution that is $N(\mu, \sigma^2)$, where $\sigma^2 > 0$. Show that the sum $Z_n = \sum_1^n X_i$ does not have a limiting distribution.

5.2.7. Let X_n have a gamma distribution with parameter $\alpha = n$ and β , where β is not a function of n . Let $Y_n = X_n/n$. Find the limiting distribution of Y_n .

5.2.8. Let Z_n be $\chi^2(n)$ and let $W_n = Z_n/n^2$. Find the limiting distribution of W_n .

5.2.9. Let X be $\chi^2(50)$. Using the limiting distribution discussed in Example 5.2.7, approximate $P(40 < X < 60)$. Compare your answer with that calculated by R.

5.2.10. Modify the R function `cdisplt` to show histograms of the values w_n discussed in Example 5.2.8.

5.2.11. Let $p = 0.95$ be the probability that a man, in a certain age group, lives at least 5 years.

- (a) If we are to observe 60 such men and if we assume independence, use R to compute the probability that at least 56 of them live 5 or more years.

- (b) Find an approximation to the result of part (a) by using the Poisson distribution.

Hint: Redefine p to be 0.05 and $1 - p = 0.95$.

5.2.12. Let the random variable Z_n have a Poisson distribution with parameter $\mu = n$. Show that the limiting distribution of the random variable $Y_n = (Z_n - n)/\sqrt{n}$ is normal with mean zero and variance 1.

5.2.13. Prove Theorem 5.2.3.

5.2.14. Let X_n and Y_n have a bivariate normal distribution with parameters $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$ (free of n) but $\rho = 1 - 1/n$. Consider the conditional distribution of Y_n , given $X_n = x$. Investigate the limit of this conditional distribution as $n \rightarrow \infty$. What is the limiting distribution if $\rho = -1 + 1/n$? Reference to these facts is made in the remark of Section 2.5.

5.2.15. Let \bar{X}_n denote the mean of a random sample of size n from a Poisson distribution with parameter $\mu = 1$.

- (a) Show that the mgf of $Y_n = \sqrt{n}(\bar{X}_n - \mu)/\sigma = \sqrt{n}(\bar{X}_n - 1)$ is given by $\exp[-t\sqrt{n} + n(e^{t/\sqrt{n}} - 1)]$.

- (b) Investigate the limiting distribution of Y_n as $n \rightarrow \infty$.

Hint: Replace, by its MacLaurin's series, the expression $e^{t/\sqrt{n}}$, which is in the exponent of the mgf of Y_n .

5.2.16. Using Exercise 5.2.15 and the Δ -method, find the limiting distribution of $\sqrt{n}(\bar{X}_n - 1)$.

5.2.17. Let \bar{X}_n denote the mean of a random sample of size n from a distribution that has pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere.

- (a) Show that the mgf $M_{Y_n}(t)$ of $Y_n = \sqrt{n}(\bar{X}_n - 1)$ is

$$M_{Y_n}(t) = [e^{t/\sqrt{n}} - (t/\sqrt{n})e^{t/\sqrt{n}}]^{-n}, \quad t < \sqrt{n}.$$

- (b) Find the limiting distribution of Y_n as $n \rightarrow \infty$.

Exercises 5.2.15 and 5.2.17 are special instances of an important theorem that will be proved in the next section.

5.2.18. Continuing with Exercise 5.2.17, use the Δ -method to find the limiting distribution of $\sqrt{n}(\bar{X}_n - 1)$.

5.2.19. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample (see Section 5.2) from a distribution with pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Determine the limiting distribution of $Z_n = (Y_n - \log n)$.

5.2.20. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample (see Section 5.2) from a distribution with pdf $f(x) = 5x^4$, $0 < x < 1$, zero elsewhere. Find p so that $Z_n = n^p Y_1$ converges in distribution.

5.2.21. Consider Stirling's formula (5.2.2):

- (a) Run the following R code to check this formula for $k = 5$ to $k = 15$.

```
ks = 5; kstp = 15; coll = c();for(j in ks:kstp){  
  c1=gamma(j+1); c2=sqrt(2*pi)*exp(-j+(j+.5)*log(j))  
  coll=rbind(coll,c(j,c1,c2))}; coll
```

- (b) Take the log of Stirling's formula and compare it with the R computation $\lgamma(k+1)$.

- (c) Use Stirling's formula to show that the first limit in Example 5.2.3 is 1.

5.3 Central Limit Theorem

It was seen in Section 3.4 that if X_1, X_2, \dots, X_n is a random sample from a normal distribution with mean μ and variance σ^2 , the random variable

$$\frac{\sum_{i=1}^n X_i - n\mu}{\sigma\sqrt{n}} = \frac{\sqrt{n}(\bar{X}_n - \mu)}{\sigma}$$

is, for every positive integer n , normally distributed with zero mean and unit variance. In probability theory there is a very elegant theorem called the **Central Limit Theorem (CLT)**. A special case of this theorem asserts the remarkable and important fact that if X_1, X_2, \dots, X_n denote the observations of a random sample of size n from any distribution having finite variance $\sigma^2 > 0$ (and hence finite mean μ), then the random variable $\sqrt{n}(\bar{X}_n - \mu)/\sigma$ converges in distribution to a random variable having a standard normal distribution. Thus, whenever the conditions of the theorem are satisfied, for large n the random variable $\sqrt{n}(\bar{X}_n - \mu)/\sigma$ has an approximate normal distribution with mean zero and variance 1. It is then possible to use this approximate normal distribution to compute approximate probabilities concerning \bar{X} .

We often use the notation “ Y_n has a limiting standard normal distribution” to mean that Y_n converges in distribution to a standard normal random variable; see Remark 5.2.1.

The more general form of the theorem is stated, but it is proved only in the modified case. However, this is exactly the proof of the theorem that would be given if we could use the characteristic function in place of the mgf.

Theorem 5.3.1 (Central Limit Theorem). *Let X_1, X_2, \dots, X_n denote the observations of a random sample from a distribution that has mean μ and positive variance σ^2 . Then the random variable $Y_n = (\sum_{i=1}^n X_i - n\mu)/\sqrt{n}\sigma = \sqrt{n}(\bar{X}_n - \mu)/\sigma$ converges in distribution to a random variable that has a normal distribution with mean zero and variance 1.*

Proof: For this proof, additionally assume that the mgf $M(t) = E(e^{tX})$ exists for $-h < t < h$. If one replaces the mgf by the characteristic function $\varphi(t) = E(e^{itX})$, which always exists, then our proof is essentially the same as the proof in a more advanced course which uses characteristic functions.

The function

$$m(t) = E[e^{t(X-\mu)}] = e^{-\mu t}M(t)$$

also exists for $-h < t < h$. Since $m(t)$ is the mgf for $X - \mu$, it must follow that $m(0) = 1$, $m'(0) = E(X - \mu) = 0$, and $m''(0) = E[(X - \mu)^2] = \sigma^2$. By Taylor's formula there exists a number ξ between 0 and t such that

$$\begin{aligned} m(t) &= m(0) + m'(0)t + \frac{m''(\xi)t^2}{2} \\ &= 1 + \frac{m''(\xi)t^2}{2}. \end{aligned}$$

If $\sigma^2 t^2/2$ is added and subtracted, then

$$m(t) = 1 + \frac{\sigma^2 t^2}{2} + \frac{[m''(\xi) - \sigma^2]t^2}{2} \quad (5.3.1)$$

Next consider $M(t; n)$, where

$$\begin{aligned} M(t; n) &= E \left[\exp \left(t \frac{\sum X_i - n\mu}{\sigma\sqrt{n}} \right) \right] \\ &= E \left[\exp \left(t \frac{X_1 - \mu}{\sigma\sqrt{n}} \right) \exp \left(t \frac{X_2 - \mu}{\sigma\sqrt{n}} \right) \cdots \exp \left(t \frac{X_n - \mu}{\sigma\sqrt{n}} \right) \right] \\ &= E \left[\exp \left(t \frac{X_1 - \mu}{\sigma\sqrt{n}} \right) \right] \cdots E \left[\exp \left(t \frac{X_n - \mu}{\sigma\sqrt{n}} \right) \right] \\ &= \left\{ E \left[\exp \left(t \frac{X - \mu}{\sigma\sqrt{n}} \right) \right] \right\}^n \\ &= \left[m \left(\frac{t}{\sigma\sqrt{n}} \right) \right]^n, \quad -h < \frac{t}{\sigma\sqrt{n}} < h. \end{aligned}$$

In equation (5.3.1), replace t by $t/\sigma\sqrt{n}$ to obtain

$$m \left(\frac{t}{\sigma\sqrt{n}} \right) = 1 + \frac{t^2}{2n} + \frac{[m''(\xi) - \sigma^2]t^2}{2n\sigma^2},$$

where now ξ is between 0 and $t/\sigma\sqrt{n}$ with $-h\sigma\sqrt{n} < t < h\sigma\sqrt{n}$. Accordingly,

$$M(t; n) = \left\{ 1 + \frac{t^2}{2n} + \frac{[m''(\xi) - \sigma^2]t^2}{2n\sigma^2} \right\}^n.$$

Since $m''(t)$ is continuous at $t = 0$ and since $\xi \rightarrow 0$ as $n \rightarrow \infty$, we have

$$\lim_{n \rightarrow \infty} [m''(\xi) - \sigma^2] = 0.$$

The limit proposition (5.2.16) cited in Section 5.2 shows that

$$\lim_{n \rightarrow \infty} M(t; n) = e^{t^2/2},$$

for all real values of t . This proves that the random variable $Y_n = \sqrt{n}(\bar{X}_n - \mu)/\sigma$ has a limiting standard normal distribution. ■

As cited in Remark 5.2.1, we say that Y_n has a limiting standard normal distribution. We interpret this theorem as saying that when n is a large, fixed positive integer, the random variable \bar{X} has an approximate normal distribution with mean μ and variance σ^2/n ; and in applications we often use the approximate normal pdf as though it were the exact pdf of \bar{X} . Also, we can equivalently state the conclusion of the Central Limit Theorem as

$$\sqrt{n}(\bar{X} - \mu) \xrightarrow{\mathcal{D}} N(0, \sigma^2). \quad (5.3.2)$$

This is often a convenient formulation to use.

One of the key applications of the Central Limit Theorem is for statistical inference. In Examples 5.3.1–5.3.6, we present results for several such applications. As we point out, we made use of these results in Chapter 4, but we will also use them in the remainder of the book.

Example 5.3.1 (Large Sample Inference for μ). Let X_1, X_2, \dots, X_n be a random sample from a distribution with mean μ and variance σ^2 , where μ and σ^2 are unknown. Let \bar{X} and S be the sample mean and sample standard deviation, respectively. Then

$$\frac{\bar{X} - \mu}{S/\sqrt{n}} \xrightarrow{\mathcal{D}} N(0, 1). \quad (5.3.3)$$

To see this, write the left side as

$$\frac{\bar{X} - \mu}{S/\sqrt{n}} = \left(\frac{\sigma}{S} \right) \frac{(\bar{X} - \mu)}{\sigma/\sqrt{n}}.$$

Example 5.1.1 shows that S converges in probability to σ and, hence, by the theorems of Section 5.2, that σ/S converges in probability to 1. Thus the result (5.3.3) follows from the CLT and Slutsky's Theorem, Theorem 5.2.5.

In Examples 4.2.2 and 4.5.3 of Chapter 4, we presented large sample confidence intervals and tests for μ based on (5.3.3). ■

Some illustrative examples, here and below, help show the importance of this version of the CLT.

Example 5.3.2. Let \bar{X} denote the mean of a random sample of size 75 from the distribution that has the pdf

$$f(x) = \begin{cases} 1 & 0 < x < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

For this situation, it can be shown that the pdf of \bar{X} , $g(\bar{x})$, has a graph when $0 < \bar{x} < 1$ that is composed of arcs of 75 different polynomials of degree 74. The computation of such a probability as $P(0.45 < \bar{X} < 0.55)$ would be extremely laborious. The conditions of the theorem are satisfied, since $M(t)$ exists for all real values of t . Moreover, $\mu = \frac{1}{2}$ and $\sigma^2 = \frac{1}{12}$, so that using R we have approximately

$$\begin{aligned} P(0.45 < \bar{X} < 0.55) &= P\left[\frac{\sqrt{n}(0.45 - \mu)}{\sigma} < \frac{\sqrt{n}(\bar{X} - \mu)}{\sigma} < \frac{\sqrt{n}(0.55 - \mu)}{\sigma}\right] \\ &= P[-1.5 < 30(\bar{X} - 0.5) < 1.5] \\ &\approx \text{pnorm}(1.5) - \text{pnorm}(-1.5) = 0.8663. \end{aligned}$$

■

Example 5.3.3 (Normal Approximation to the Binomial Distribution). Suppose that X_1, X_2, \dots, X_n is a random sample from a distribution that is $b(1, p)$. Here $\mu = p$, $\sigma^2 = p(1 - p)$, and $M(t)$ exists for all real values of t . If $Y_n = X_1 + \dots + X_n$, it is known that Y_n is $b(n, p)$. Calculations of probabilities for Y_n , when we do not use the Poisson approximation, are simplified by making use of the fact that $(Y_n - np)/\sqrt{np(1 - p)} = \sqrt{n}(\bar{X}_n - p)/\sqrt{p(1 - p)} = \sqrt{n}(\bar{X}_n - \mu)/\sigma$ has a limiting distribution that is normal with mean zero and variance 1.

Frequently, statisticians say that Y_n , or more simply Y , has an approximate normal distribution with mean np and variance $np(1 - p)$. Even with n as small as 10, with $p = \frac{1}{2}$ so that the binomial distribution is symmetric about $np = 5$, we note in Figure 5.3.1 how well the normal distribution, $N(5, \frac{5}{2})$, fits the binomial distribution, $b(10, \frac{1}{2})$, where the heights of the rectangles represent the probabilities of the respective integers $0, 1, 2, \dots, 10$. Note that the area of the rectangle whose base is $(k - 0.5, k + 0.5)$ and the area under the normal pdf between $k - 0.5$ and $k + 0.5$ are approximately equal for each $k = 0, 1, 2, \dots, 10$, even with $n = 10$. This example should help the reader understand Example 5.3.4. ■

Example 5.3.4. With the background of Example 5.3.3, let $n = 100$ and $p = \frac{1}{2}$, and suppose that we wish to compute $P(Y = 48, 49, 50, 51, 52)$. Since Y is a random variable of the discrete type, $\{Y = 48, 49, 50, 51, 52\}$ and $\{47.5 < Y < 52.5\}$ are equivalent events. That is, $P(Y = 48, 49, 50, 51, 52) = P(47.5 < Y < 52.5)$. Since $np = 50$ and $np(1 - p) = 25$, the latter probability may be written

$$\begin{aligned} P(47.5 < Y < 52.5) &= P\left(\frac{47.5 - 50}{5} < \frac{Y - 50}{5} < \frac{52.5 - 50}{5}\right) \\ &= P\left(-0.5 < \frac{Y - 50}{5} < 0.5\right). \end{aligned}$$

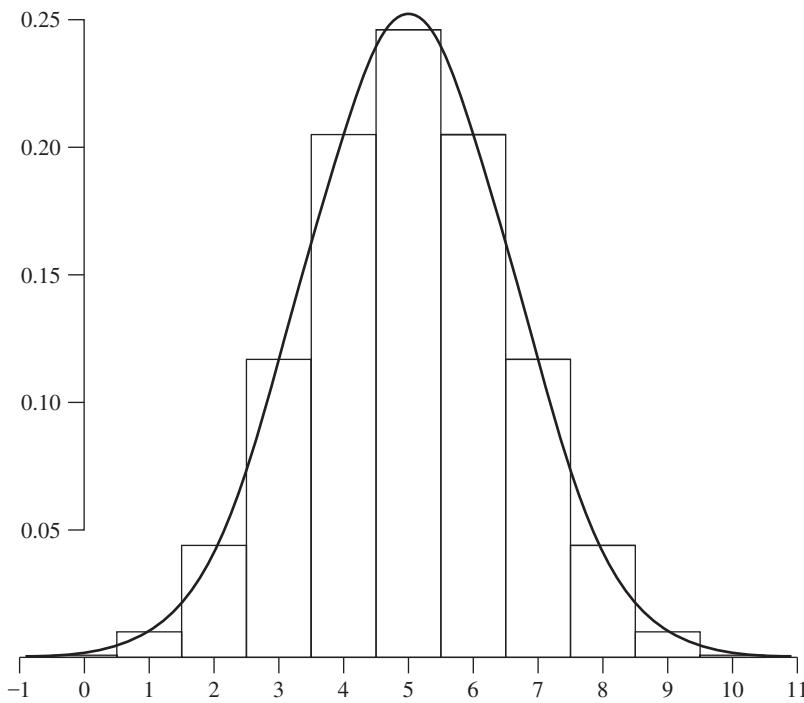

Figure 5.3.1: The $b(10, \frac{1}{2})$ pmf overlaid by the $N(5, \frac{5}{2})$ pdf.

Since $(Y - 50)/5$ has an approximate normal distribution with mean zero and variance 1, the probability is approximately $\text{pnorm}(.5) - \text{pnorm}(-.5) = 0.3829$.

The convention of selecting the event $47.5 < Y < 52.5$, instead of another event, say, $47.8 < Y < 52.3$, as the event equivalent to the event $Y = 48, 49, 50, 51, 52$ is due to the following observation. The probability $P(Y = 48, 49, 50, 51, 52)$ can be interpreted as the sum of five rectangular areas where the rectangles have widths 1 and the heights are respectively $P(Y = 48), \dots, P(Y = 52)$. If these rectangles are so located that the midpoints of their bases are, respectively, at the points $48, 49, \dots, 52$ on a horizontal axis, then in approximating the sum of these areas by an area bounded by the horizontal axis, the graph of a normal pdf, and two ordinates, it seems reasonable to take the two ordinates at the points 47.5 and 52.5. This is called the **continuity correction**. ■

We next present two examples concerning large sample inference for proportions.

Example 5.3.5 (Large Sample Inference for Proportions). Let X_1, X_2, \dots, X_n be a random sample from a Bernoulli distribution with p as the probability of success. Let \hat{p} be the sample proportion of successes. Then $\hat{p} = \bar{X}$. Hence,

$$\frac{\hat{p} - p}{\sqrt{\hat{p}(1 - \hat{p})/n}} \xrightarrow{D} N(0, 1). \quad (5.3.4)$$

This is readily established by using the CLT and the same reasoning as in Example 5.3.1; see Exercise 5.3.13.

In Examples 4.2.3 and 4.5.2 of Chapter 4, we presented large sample confidence intervals and tests for p using (5.3.4). ■

Example 5.3.6 (Large Sample Inference for χ^2 -Tests). Another extension of Example 5.3.3 that was used in Section 4.7 follows quickly from the Central Limit Theorem and Theorem 5.2.4. Using the notation of Example 5.3.3, suppose Y_n has a binomial distribution with parameters n and p . Then, as in Example 5.3.3, $(Y_n - np)/\sqrt{np(1-p)}$ converges in distribution to a random variable Z with the $N(0, 1)$ distribution. Hence, by Theorem 5.2.4,

$$\left(\frac{Y_n - np}{\sqrt{np(1-p)}} \right)^2 \xrightarrow{D} \chi^2(1). \quad (5.3.5)$$

This was the result referenced in Chapter 4; see expression (4.7.1). ■

We know that \bar{X} and $\sum_1^n X_i$ have approximately normal distributions, provided that n is large enough. Later, we find that other statistics also have approximate normal distributions, and this is the reason that the normal distribution is so important to statisticians. That is, while not many underlying distributions are normal, the distributions of statistics calculated from random samples arising from these distributions are often very close to being normal.

Frequently, we are interested in functions of statistics that have approximately normal distributions. To illustrate, consider the sequence of random variable Y_n of Example 5.3.3. As discussed there, Y_n has an approximate $N[np, np(1-p)]$. So $np(1-p)$ is an important function of p , as it is the variance of Y_n . Thus, if p is unknown, we might want to estimate the variance of Y_n . Since $E(Y_n/n) = p$, we might use $n(Y_n/n)(1 - Y_n/n)$ as such an estimator and would want to know something about the latter's distribution. In particular, does it also have an approximate normal distribution? If so, what are its mean and variance? To answer questions like these, we can apply the Δ -method, Theorem 5.2.9.

As an illustration of the Δ -method, we consider a function of the sample mean. Assume that X_1, \dots, X_n is a random sample on X which has finite mean μ and variance σ^2 . Then rewriting expression (5.3.2) we have by the Central Limit Theorem that

$$\sqrt{n}(\bar{X} - \mu) \xrightarrow{D} N(0, \sigma^2).$$

Hence, by the Δ -method, Theorem 5.2.9, we have

$$\sqrt{n}[g(\bar{X}) - g(\mu)] \xrightarrow{D} N(0, \sigma^2(g'(\mu))^2), \quad (5.3.6)$$

for a continuous transformation $g(x)$ such that $g'(\mu) \neq 0$.

Example 5.3.7. Assume that we are sampling from a binomial $b(1, p)$ distribution. Then \bar{X} is the sample proportion of successes. Here $\mu = p$ and $\sigma^2 = p(1-p)$. Suppose that we want a transformation $g(p)$ such that the transformed asymptotic

variance is constant; in particular, it is free of p . Hence, we seek a transformation $g(p)$ such that

$$g'(p) = \frac{c}{\sqrt{p(1-p)}},$$

for some constant c . Integrating both sides and making the change-of-variables $z = p$, $dz = 1/(2\sqrt{p}) dp$, we have

$$\begin{aligned} g(p) &= c \int \frac{1}{\sqrt{p(1-p)}} dp \\ &= 2c \int \frac{1}{\sqrt{1-z^2}} dz = 2c \arcsin(z) = 2c \arcsin(\sqrt{p}). \end{aligned}$$

Taking $c = 1/2$, for the statistic $g(\bar{X}) = \arcsin(\sqrt{\bar{X}})$, we obtain

$$\sqrt{n} \left[\arcsin(\sqrt{\bar{X}}) - \arcsin(\sqrt{p}) \right] \xrightarrow{\mathcal{D}} N\left(0, \frac{1}{4}\right).$$

Several other such examples are given in the exercises. ■

EXERCISES

5.3.1. Let \bar{X} denote the mean of a random sample of size 100 from a distribution that is $\chi^2(50)$. Compute an approximate value of $P(49 < \bar{X} < 51)$.

5.3.2. Let \bar{X} denote the mean of a random sample of size 128 from a gamma distribution with $\alpha = 2$ and $\beta = 4$. Approximate $P(7 < \bar{X} < 9)$.

5.3.3. Let Y be $b(72, \frac{1}{3})$. Approximate $P(22 \leq Y \leq 28)$.

5.3.4. Compute an approximate probability that the mean of a random sample of size 15 from a distribution having pdf $f(x) = 3x^2$, $0 < x < 1$, zero elsewhere, is between $\frac{3}{5}$ and $\frac{4}{5}$.

5.3.5. Let Y denote the sum of the observations of a random sample of size 12 from a distribution having pmf $p(x) = \frac{1}{6}$, $x = 1, 2, 3, 4, 5, 6$, zero elsewhere. Compute an approximate value of $P(36 \leq Y \leq 48)$.

Hint: Since the event of interest is $Y = 36, 37, \dots, 48$, rewrite the probability as $P(35.5 < Y < 48.5)$.

5.3.6. Let Y be $b(400, \frac{1}{5})$. Compute an approximate value of $P(0.25 < Y/400)$.

5.3.7. If Y is $b(100, \frac{1}{2})$, approximate the value of $P(Y = 50)$.

5.3.8. Let Y be $b(n, 0.55)$. Find the smallest value of n such that (approximately) $P(Y/n > \frac{1}{2}) \geq 0.95$.

5.3.9. Let $f(x) = 1/x^2$, $1 < x < \infty$, zero elsewhere, be the pdf of a random variable X . Consider a random sample of size 72 from the distribution having this pdf. Compute approximately the probability that more than 50 of the observations of the random sample are less than 3.

5.3.10. Forty-eight measurements are recorded to several decimal places. Each of these 48 numbers is rounded off to the nearest integer. The sum of the original 48 numbers is approximated by the sum of these integers. If we assume that the errors made by rounding off are iid and have a uniform distribution over the interval $(-\frac{1}{2}, \frac{1}{2})$, compute approximately the probability that the sum of the integers is within two units of the true sum.

5.3.11. We know that \bar{X} is approximately $N(\mu, \sigma^2/n)$ for large n . Find the approximate distribution of $u(\bar{X}) = \bar{X}^3$, provided that $\mu \neq 0$.

5.3.12. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with mean μ . Thus, $Y = \sum_{i=1}^n X_i$ has a Poisson distribution with mean $n\mu$. Moreover, $\bar{X} = Y/n$ is approximately $N(\mu, \mu/n)$ for large n . Show that $u(Y/n) = \sqrt{Y/n}$ is a function of Y/n whose variance is essentially free of μ .

5.3.13. Using the notation of Example 5.3.5, show that equation (5.3.4) is true.

5.3.14. Assume that X_1, \dots, X_n is a random sample from a $\Gamma(1, \beta)$ distribution. Determine the asymptotic distribution of $\sqrt{n}(\bar{X} - \beta)$. Then find a transformation $g(\bar{X})$ whose asymptotic variance is free of β .

5.4 *Extensions to Multivariate Distributions

In this section, we briefly discuss asymptotic concepts for sequences of random vectors. The concepts introduced for univariate random variables generalize in a straightforward manner to the multivariate case. Our development is brief, and the interested reader can consult more advanced texts for more depth; see Serfling (1980).

We need some notation. For a vector $\mathbf{v} \in R^p$, recall the Euclidean norm of \mathbf{v} is defined to be

$$\|\mathbf{v}\| = \sqrt{\sum_{i=1}^p v_i^2}. \quad (5.4.1)$$

This norm satisfies the usual three properties given by

- (a) For all $\mathbf{v} \in R^p$, $\|\mathbf{v}\| \geq 0$, and $\|\mathbf{v}\| = 0$ if and only if $\mathbf{v} = \mathbf{0}$.
- (b) For all $\mathbf{v} \in R^p$ and $a \in R$, $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$.
- (c) For all $\mathbf{v}, \mathbf{u} \in R^p$, $\|\mathbf{u} + \mathbf{v}\| \leq \|\mathbf{u}\| + \|\mathbf{v}\|$.

Denote the standard basis of R^p by the vectors $\mathbf{e}_1, \dots, \mathbf{e}_p$, where all the components of \mathbf{e}_i are 0 except for the i th component, which is 1. Then we can write any vector

$\mathbf{v}' = (v_1, \dots, v_p)$ as

$$\mathbf{v} = \sum_{i=1}^p v_i \mathbf{e}_i.$$

The following lemma will be useful:

Lemma 5.4.1. *Let $\mathbf{v}' = (v_1, \dots, v_p)$ be any vector in R^p . Then*

$$|v_j| \leq \|\mathbf{v}\| \leq \sum_{i=1}^n |v_i|, \quad \text{for all } j = 1, \dots, p. \quad (5.4.3)$$

Proof. Note that for all j ,

$$v_j^2 \leq \sum_{i=1}^p v_i^2 = \|\mathbf{v}\|^2;$$

hence, taking the square root of this equality leads to the first part of the desired inequality. The second part is

$$\|\mathbf{v}\| = \left\| \sum_{i=1}^p v_i \mathbf{e}_i \right\| \leq \sum_{i=1}^p |v_i| \|\mathbf{e}_i\| = \sum_{i=1}^p |v_i|. \quad \blacksquare$$

Let $\{\mathbf{X}_n\}$ denote a sequence of p -dimensional vectors. Because the absolute value is the Euclidean norm in R^1 , the definition of convergence in probability for random vectors is an immediate generalization:

Definition 5.4.1. *Let $\{\mathbf{X}_n\}$ be a sequence of p -dimensional vectors and let \mathbf{X} be a random vector, all defined on the same sample space. We say that $\{\mathbf{X}_n\}$ converges in probability to \mathbf{X} if*

$$\lim_{n \rightarrow \infty} P[\|\mathbf{X}_n - \mathbf{X}\| \geq \epsilon] = 0, \quad (5.4.4)$$

for all $\epsilon > 0$. As in the univariate case, we write $\mathbf{X}_n \xrightarrow{P} \mathbf{X}$.

As the next theorem shows, convergence in probability of vectors is equivalent to componentwise convergence in probability.

Theorem 5.4.1. *Let $\{\mathbf{X}_n\}$ be a sequence of p -dimensional vectors and let \mathbf{X} be a random vector, all defined on the same sample space. Then*

$$\mathbf{X}_n \xrightarrow{P} \mathbf{X} \text{ if and only if } X_{nj} \xrightarrow{P} X_j \text{ for all } j = 1, \dots, p.$$

Proof: This follows immediately from Lemma 5.4.1. Suppose $\mathbf{X}_n \xrightarrow{P} \mathbf{X}$. For any j , from the first part of the inequality (5.4.3), we have, for $\epsilon > 0$,

$$\epsilon \leq |X_{nj} - X_j| \leq \|\mathbf{X}_n - \mathbf{X}\|.$$

Hence

$$\overline{\lim}_{n \rightarrow \infty} P[|X_{nj} - X_j| \geq \epsilon] \leq \overline{\lim}_{n \rightarrow \infty} P[\|\mathbf{X}_n - \mathbf{X}\| \geq \epsilon] = 0,$$

which is the desired result.

Conversely, if $X_{nj} \xrightarrow{P} X_j$ for all $j = 1, \dots, p$, then by the second part of the inequality (5.4.3),

$$\epsilon \leq \|\mathbf{X}_n - \mathbf{X}\| \leq \sum_{i=1}^p |X_{nj} - X_j|,$$

for any $\epsilon > 0$. Hence

$$\begin{aligned} \overline{\lim}_{n \rightarrow \infty} P[\|\mathbf{X}_n - \mathbf{X}\| \geq \epsilon] &\leq \overline{\lim}_{n \rightarrow \infty} P\left[\sum_{j=1}^p |X_{nj} - X_j| \geq \epsilon\right] \\ &\leq \sum_{j=1}^p \overline{\lim}_{n \rightarrow \infty} P[|X_{nj} - X_j| \geq \epsilon/p] = 0. \quad \blacksquare \end{aligned}$$

Based on this result, many of the theorems involving convergence in probability can easily be extended to the multivariate setting. Some of these results are given in the exercises. This is true of statistical results, too. For example, in Section 5.2, we showed that if X_1, \dots, X_n is a random sample from the distribution of a random variable X with mean, μ , and variance, σ^2 , then \bar{X}_n and S_n^2 are consistent estimates of μ and σ^2 . By the last theorem, we have that (\bar{X}_n, S_n^2) is a consistent estimate of (μ, σ^2) .

As another simple application, consider the multivariate analog of the sample mean and sample variance. Let $\{\mathbf{X}_n\}$ be a sequence of iid random vectors with common mean vector $\boldsymbol{\mu}$ and variance-covariance matrix $\boldsymbol{\Sigma}$. Denote the vector of means by

$$\bar{\mathbf{X}}_n = \frac{1}{n} \sum_{i=1}^n \mathbf{X}_i. \quad (5.4.5)$$

Of course, $\bar{\mathbf{X}}_n$ is just the vector of sample means, $(\bar{X}_1, \dots, \bar{X}_p)'$. By the Weak Law of Large Numbers, Theorem 5.1.1, $\bar{X}_j \rightarrow \mu_j$, in probability, for each j . Hence, by Theorem 5.4.1, $\bar{\mathbf{X}}_n \rightarrow \boldsymbol{\mu}$, in probability.

How about the analog of the sample variances? Let $\mathbf{X}_i = (X_{i1}, \dots, X_{ip})'$. Define the sample variances and covariances by

$$S_{n,j}^2 = \frac{1}{n-1} \sum_{i=1}^n (X_{ij} - \bar{X}_j)^2, \quad \text{for } j = 1, \dots, p, \quad (5.4.6)$$

$$S_{n,jk} = \frac{1}{n-1} \sum_{i=1}^n (X_{ij} - \bar{X}_j)(X_{ik} - \bar{X}_k), \quad \text{for } j \neq k = 1, \dots, p. \quad (5.4.7)$$

Assuming finite fourth moments, the Weak Law of Large Numbers shows that all these componentwise sample variances and sample covariances converge in probability to distribution variances and covariances, respectively. As in our discussion after the Weak Law of Large Numbers, the Strong Law of Large Numbers implies that this convergence is true under the weaker assumption of the existence of finite

second moments. If we define the $p \times p$ matrix \mathbf{S} to be the matrix with the j th diagonal entry $S_{n,j}^2$ and (j, k) th entry $S_{n,jk}$, then $\mathbf{S} \rightarrow \boldsymbol{\Sigma}$, in probability.

The definition of convergence in distribution remains the same. We state it here in terms of vector notation.

Definition 5.4.2. Let $\{\mathbf{X}_n\}$ be a sequence of random vectors with \mathbf{X}_n having distribution function $F_n(\mathbf{x})$ and \mathbf{X} be a random vector with distribution function $F(\mathbf{x})$. Then $\{\mathbf{X}_n\}$ converges in distribution to \mathbf{X} if

$$\lim_{n \rightarrow \infty} F_n(\mathbf{x}) = F(\mathbf{x}), \quad (5.4.8)$$

for all points \mathbf{x} at which $F(\mathbf{x})$ is continuous. We write $\mathbf{X}_n \xrightarrow{D} \mathbf{X}$.

In the multivariate case, there are analogs to many of the theorems in Section 5.2. We state two important theorems without proof.

Theorem 5.4.2. Let $\{\mathbf{X}_n\}$ be a sequence of random vectors that converges in distribution to a random vector \mathbf{X} and let $g(\mathbf{x})$ be a function that is continuous on the support of \mathbf{X} . Then $g(\mathbf{X}_n)$ converges in distribution to $g(\mathbf{X})$.

We can apply this theorem to show that convergence in distribution implies marginal convergence. Simply take $g(\mathbf{x}) = x_j$, where $\mathbf{x} = (x_1, \dots, x_p)'$. Since g is continuous, the desired result follows.

It is often difficult to determine convergence in distribution by using the definition. As in the univariate case, convergence in distribution is equivalent to convergence of moment generating functions, which we state in the following theorem.

Theorem 5.4.3. Let $\{\mathbf{X}_n\}$ be a sequence of random vectors with \mathbf{X}_n having distribution function $F_n(\mathbf{x})$ and moment generating function $M_n(\mathbf{t})$. Let \mathbf{X} be a random vector with distribution function $F(\mathbf{x})$ and moment generating function $M(\mathbf{t})$. Then $\{\mathbf{X}_n\}$ converges in distribution to \mathbf{X} if and only if, for some $h > 0$,

$$\lim_{n \rightarrow \infty} M_n(\mathbf{t}) = M(\mathbf{t}), \quad (5.4.9)$$

for all \mathbf{t} such that $\|\mathbf{t}\| < h$.

The proof of this theorem can be found in more advanced books; see, for instance, Tucker (1967). Also, the usual proof is for characteristic functions instead of moment generating functions. As we mentioned previously, characteristic functions always exist, so convergence in distribution is completely characterized by convergence of corresponding characteristic functions.

The moment generating function of \mathbf{X}_n is $E[\exp\{\mathbf{t}'\mathbf{X}_n\}]$. Note that $\mathbf{t}'\mathbf{X}_n$ is a random variable. We can frequently use this and univariate theory to derive results in the multivariate case. A perfect example of this is the multivariate central limit theorem.

Theorem 5.4.4 (Multivariate Central Limit Theorem). Let $\{\mathbf{X}_n\}$ be a sequence of iid random vectors with common mean vector $\boldsymbol{\mu}$ and variance-covariance matrix

Σ which is positive definite. Assume that the common moment generating function $M(\mathbf{t})$ exists in an open neighborhood of $\mathbf{0}$. Let

$$\mathbf{Y}_n = \frac{1}{\sqrt{n}} \sum_{i=1}^n (\mathbf{X}_i - \boldsymbol{\mu}) = \sqrt{n}(\bar{\mathbf{X}} - \boldsymbol{\mu}).$$

Then \mathbf{Y}_n converges in distribution to a $N_p(\mathbf{0}, \Sigma)$ distribution.

Proof. Let $\mathbf{t} \in R^p$ be a vector in the stipulated neighborhood of $\mathbf{0}$. The moment generating function of \mathbf{Y}_n is

$$\begin{aligned} M_n(\mathbf{t}) &= E \left[\exp \left\{ \mathbf{t}' \frac{1}{\sqrt{n}} \sum_{i=1}^n (\mathbf{X}_i - \boldsymbol{\mu}) \right\} \right] \\ &= E \left[\exp \left\{ \frac{1}{\sqrt{n}} \sum_{i=1}^n \mathbf{t}' (\mathbf{X}_i - \boldsymbol{\mu}) \right\} \right] \\ &= E \left[\exp \left\{ \frac{1}{\sqrt{n}} \sum_{i=1}^n W_i \right\} \right], \end{aligned} \quad (5.4.10)$$

where $W_i = \mathbf{t}' (\mathbf{X}_i - \boldsymbol{\mu})$. Note that W_1, \dots, W_n are iid with mean 0 and variance $\text{Var}(W_i) = \mathbf{t}' \Sigma \mathbf{t}$. Hence, by the simple Central Limit Theorem,

$$\frac{1}{\sqrt{n}} \sum_{i=1}^n W_i \xrightarrow{D} N(0, \mathbf{t}' \Sigma \mathbf{t}). \quad (5.4.11)$$

Expression (5.4.10), though, is the mgf of $(1/\sqrt{n}) \sum_{i=1}^n W_i$ evaluated at 1. Therefore, by (5.4.11), we must have

$$M_n(\mathbf{t}) = E \left[\exp \left\{ (1) \frac{1}{\sqrt{n}} \sum_{i=1}^n W_i \right\} \right] \rightarrow e^{1^2 \mathbf{t}' \Sigma \mathbf{t} / 2} = e^{\mathbf{t}' \Sigma \mathbf{t} / 2}.$$

Because the last quantity is the moment generating function of a $N_p(\mathbf{0}, \Sigma)$ distribution, we have the desired result. ■

Suppose $\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_n$ is a random sample from a distribution with mean vector $\boldsymbol{\mu}$ and variance-covariance matrix Σ . Let $\bar{\mathbf{X}}_n$ be the vector of sample means. Then, from the Central Limit Theorem, we say that

$$\bar{\mathbf{X}}_n \text{ has an approximate } N_p(\boldsymbol{\mu}, \frac{1}{n} \Sigma) \text{ distribution.} \quad (5.4.12)$$

A result that we use frequently concerns linear transformations. Its proof is obtained by using moment generating functions and is left as an exercise.

Theorem 5.4.5. *Let $\{\mathbf{X}_n\}$ be a sequence of p -dimensional random vectors. Suppose $\mathbf{X}_n \xrightarrow{D} N(\boldsymbol{\mu}, \Sigma)$. Let \mathbf{A} be an $m \times p$ matrix of constants and let \mathbf{b} be an m -dimensional vector of constants. Then $\mathbf{A}\mathbf{X}_n + \mathbf{b} \xrightarrow{D} N(\mathbf{A}\boldsymbol{\mu} + \mathbf{b}, \mathbf{A}\Sigma\mathbf{A}')$.*

A result that will prove to be quite useful is the extension of the Δ -method; see Theorem 5.2.9. A proof can be found in Chapter 3 of Serfling (1980).

Theorem 5.4.6. *Let $\{\mathbf{X}_n\}$ be a sequence of p -dimensional random vectors. Suppose*

$$\sqrt{n}(\mathbf{X}_n - \boldsymbol{\mu}_0) \xrightarrow{D} N_p(\mathbf{0}, \boldsymbol{\Sigma}).$$

Let \mathbf{g} be a transformation $\mathbf{g}(\mathbf{x}) = (g_1(\mathbf{x}), \dots, g_k(\mathbf{x}))'$ such that $1 \leq k \leq p$ and the $k \times p$ matrix of partial derivatives,

$$\mathbf{B} = \left[\frac{\partial g_i}{\partial \mu_j} \right], \quad i = 1, \dots, k; j = 1, \dots, p,$$

are continuous and do not vanish in a neighborhood of $\boldsymbol{\mu}_0$. Let $\mathbf{B}_0 = \mathbf{B}$ at $\boldsymbol{\mu}_0$. Then

$$\sqrt{n}(\mathbf{g}(\mathbf{X}_n) - \mathbf{g}(\boldsymbol{\mu}_0)) \xrightarrow{D} N_k(\mathbf{0}, \mathbf{B}_0 \boldsymbol{\Sigma} \mathbf{B}'_0). \quad (5.4.13)$$

EXERCISES

5.4.1. Let $\{\mathbf{X}_n\}$ be a sequence of p -dimensional random vectors. Show that

$$\mathbf{X}_n \xrightarrow{D} N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text{ if and only if } \mathbf{a}' \mathbf{X}_n \xrightarrow{D} N_1(\mathbf{a}' \boldsymbol{\mu}, \mathbf{a}' \boldsymbol{\Sigma} \mathbf{a}),$$

for all vectors $\mathbf{a} \in R^p$.

5.4.2. Let X_1, \dots, X_n be a random sample from a uniform(a, b) distribution. Let $Y_1 = \min X_i$ and let $Y_2 = \max X_i$. Show that $(Y_1, Y_2)'$ converges in probability to the vector $(a, b)'$.

5.4.3. Let \mathbf{X}_n and \mathbf{Y}_n be p -dimensional random vectors. Show that if

$$\mathbf{X}_n - \mathbf{Y}_n \xrightarrow{P} \mathbf{0} \text{ and } \mathbf{X}_n \xrightarrow{D} \mathbf{X},$$

where \mathbf{X} is a p -dimensional random vector, then $\mathbf{Y}_n \xrightarrow{D} \mathbf{X}$.

5.4.4. Let \mathbf{X}_n and \mathbf{Y}_n be p -dimensional random vectors such that \mathbf{X}_n and \mathbf{Y}_n are independent for each n and their mgfs exist. Show that if

$$\mathbf{X}_n \xrightarrow{D} \mathbf{X} \text{ and } \mathbf{Y}_n \xrightarrow{D} \mathbf{Y},$$

where \mathbf{X} and \mathbf{Y} are p -dimensional random vectors, then $(\mathbf{X}_n, \mathbf{Y}_n) \xrightarrow{D} (\mathbf{X}, \mathbf{Y})$.

5.4.5. Suppose \mathbf{X}_n has a $N_p(\boldsymbol{\mu}_n, \boldsymbol{\Sigma}_n)$ distribution. Show that

$$\mathbf{X}_n \xrightarrow{D} N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text{ iff } \boldsymbol{\mu}_n \rightarrow \boldsymbol{\mu} \text{ and } \boldsymbol{\Sigma}_n \rightarrow \boldsymbol{\Sigma}.$$

Chapter 6

Maximum Likelihood Methods

6.1 Maximum Likelihood Estimation

Recall in Chapter 4 that as a point estimation procedure, we introduced maximum likelihood estimates (mle). In this chapter, we continue this development showing that these likelihood procedures give rise to a formal theory of statistical inference (confidence and testing procedures). Under certain conditions (regularity conditions), these procedures are asymptotically optimal.

As in Section 4.1, consider a random variable X whose pdf $f(x; \theta)$ depends on an unknown parameter θ which is in a set Ω . Our general discussion is for the continuous case, but the results extend to the discrete case also. For information, suppose that we have a random sample X_1, \dots, X_n on X ; i.e., X_1, \dots, X_n are iid random variables with common pdf $f(x; \theta), \theta \in \Omega$. For now, we assume that θ is a scalar, but we do extend the results to vectors in Sections 6.4 and 6.5. The parameter θ is unknown. The basis of our inferential procedures is the likelihood function given by

$$L(\theta; \mathbf{x}) = \prod_{i=1}^n f(x_i; \theta), \quad \theta \in \Omega, \tag{6.1.1}$$

where $\mathbf{x} = (x_1, \dots, x_n)'$. Because we treat L as a function of θ in this chapter, we have transposed the x_i and θ in the argument of the likelihood function. In fact, we often write it as $L(\theta)$. Actually, the log of this function is usually more convenient to use and we denote it by

$$l(\theta) = \log L(\theta) = \sum_{i=1}^n \log f(x_i; \theta), \quad \theta \in \Omega. \tag{6.1.2}$$

Note that there is no loss of information in using $l(\theta)$ because the log is a one-to-one function. Most of our discussion in this chapter remains the same if X is a random vector.

As in Chapter 4, our point estimator of θ is $\hat{\theta} = \hat{\theta}(X_1, \dots, X_n)$, where $\hat{\theta}$ maximizes the function $L(\theta)$. We call $\hat{\theta}$ the maximum likelihood estimator (mle) of θ . In Section 4.1, several motivating examples were given, including the binomial and normal probability models. Later we give several more examples, but first we offer a theoretical justification for considering the mle. Let θ_0 denote the *true value* of θ . Theorem 6.1.1 shows that the maximum of $L(\theta)$ asymptotically separates the true model at θ_0 from models at $\theta \neq \theta_0$. To prove this theorem, certain assumptions, *regularity conditions*, are required.

Assumptions 6.1.1 (Regularity Conditions). *Regularity conditions (R0)–(R2) are*

- (R0) *The cdfs are distinct; i.e., $\theta \neq \theta' \Rightarrow F(x_i; \theta) \neq F(x_i; \theta')$.*
- (R1) *The pdfs have common support for all θ .*
- (R2) *The point θ_0 is an interior point in Ω .*

The first assumption states that the parameter identifies the pdf. The second assumption implies that the support of X_i does not depend on θ . This is restrictive, and some examples and exercises cover models in which (R1) is not true.

Theorem 6.1.1. *Assume that θ_0 is the true parameter and that $E_{\theta_0}[f(X_i; \theta)/f(X_i; \theta_0)]$ exists. Under assumptions (R0) and (R1),*

$$\lim_{n \rightarrow \infty} P_{\theta_0}[L(\theta_0, \mathbf{X}) > L(\theta, \mathbf{X})] = 1, \quad \text{for all } \theta \neq \theta_0. \quad (6.1.3)$$

Proof: By taking logs, the inequality $L(\theta_0, \mathbf{X}) > L(\theta, \mathbf{X})$ is equivalent to

$$\frac{1}{n} \sum_{i=1}^n \log \left[\frac{f(X_i; \theta)}{f(X_i; \theta_0)} \right] < 0.$$

Since the summands are iid with finite expectation and the function $\phi(x) = -\log(x)$ is strictly convex, it follows from the Law of Large Numbers (Theorem 5.1.1) and Jensen's inequality (Theorem 1.10.5) that, when θ_0 is the true parameter,

$$\frac{1}{n} \sum_{i=1}^n \log \left[\frac{f(X_i; \theta)}{f(X_i; \theta_0)} \right] \xrightarrow{P} E_{\theta_0} \left[\log \frac{f(X_1; \theta)}{f(X_1; \theta_0)} \right] < \log E_{\theta_0} \left[\frac{f(X_1; \theta)}{f(X_1; \theta_0)} \right].$$

But

$$E_{\theta_0} \left[\frac{f(X_1; \theta)}{f(X_1; \theta_0)} \right] = \int \frac{f(x; \theta)}{f(x; \theta_0)} f(x; \theta_0) dx = 1.$$

Because $\log 1 = 0$, the theorem follows. Note that common support is needed to obtain the last equalities. ■

Theorem 6.1.1 says that asymptotically the likelihood function is maximized at the true value θ_0 . So in considering estimates of θ_0 , it seems natural to consider the value of θ that maximizes the likelihood.

Definition 6.1.1 (Maximum Likelihood Estimator). *We say that $\hat{\theta} = \hat{\theta}(\mathbf{X})$ is a maximum likelihood estimator (mle) of θ if*

$$\hat{\theta} = \text{Argmax } L(\theta; \mathbf{X}). \quad (6.1.4)$$

The notation Argmax means that $L(\theta; \mathbf{X})$ achieves its maximum value at $\hat{\theta}$.

As in Chapter 4, to determine the mle, we often take the log of the likelihood and determine its critical value; that is, letting $l(\theta) = \log L(\theta)$, the mle solves the equation

$$\frac{\partial l(\theta)}{\partial \theta} = 0. \quad (6.1.5)$$

This is an example of an **estimating equation**, which we often label as an EE. This is the first of several EEs in the text.

Example 6.1.1 (Laplace Distribution). Let X_1, \dots, X_n be iid with density

$$f(x; \theta) = \frac{1}{2} e^{-|x-\theta|}, \quad -\infty < x < \infty, -\infty < \theta < \infty. \quad (6.1.6)$$

This pdf is referred to as either the *Laplace* or the *double exponential distribution*. The log of the likelihood simplifies to

$$l(\theta) = -n \log 2 - \sum_{i=1}^n |x_i - \theta|.$$

The first partial derivative is

$$l'(\theta) = \sum_{i=1}^n \text{sgn}(x_i - \theta), \quad (6.1.7)$$

where $\text{sgn}(t) = 1, 0$, or -1 depending on whether $t > 0$, $t = 0$, or $t < 0$. Note that we have used $\frac{d}{dt}|t| = \text{sgn}(t)$, which is true unless $t = 0$. Setting equation (6.1.7) to 0, the solution for θ is $\text{med}\{x_1, x_2, \dots, x_n\}$, because the median makes half the terms of the sum in expression (6.1.7) nonpositive and half nonnegative. Recall that we defined the sample median in expression (4.4.4) and that we denote it by Q_2 (the second quartile of the sample). Hence, $\hat{\theta} = Q_2$ is the mle of θ for the Laplace pdf (6.1.6). ■

There is no guarantee that the mle exists or, if it does, it is unique. This is often clear from the application as in the next two examples. Other examples are given in the exercises.

Example 6.1.2 (Logistic Distribution). Let X_1, \dots, X_n be iid with density

$$f(x; \theta) = \frac{\exp\{-(x-\theta)\}}{(1 + \exp\{-(x-\theta)\})^2}, \quad -\infty < x < \infty, -\infty < \theta < \infty. \quad (6.1.8)$$

The log of the likelihood simplifies to

$$l(\theta) = \sum_{i=1}^n \log f(x_i; \theta) = n\theta - n\bar{x} - 2 \sum_{i=1}^n \log(1 + \exp\{-(x_i - \theta)\}).$$

Using this, the first partial derivative is

$$l'(\theta) = n - 2 \sum_{i=1}^n \frac{\exp\{-(x_i - \theta)\}}{1 + \exp\{-(x_i - \theta)\}}. \quad (6.1.9)$$

Setting this equation to 0 and rearranging terms results in the equation

$$\sum_{i=1}^n \frac{\exp\{-(x_i - \theta)\}}{1 + \exp\{-(x_i - \theta)\}} = \frac{n}{2}. \quad (6.1.10)$$

Although this does not simplify, we can show that equation (6.1.10) has a unique solution. The derivative of the left side of equation (6.1.10) simplifies to

$$(\partial/\partial\theta) \sum_{i=1}^n \frac{\exp\{-(x_i - \theta)\}}{1 + \exp\{-(x_i - \theta)\}} = \sum_{i=1}^n \frac{\exp\{-(x_i - \theta)\}}{(1 + \exp\{-(x_i - \theta)\})^2} > 0.$$

Thus the left side of equation (6.1.10) is a strictly increasing function of θ . Finally, the left side of (6.1.10) approaches 0 as $\theta \rightarrow -\infty$ and approaches n as $\theta \rightarrow \infty$. Thus equation (6.1.10) has a unique solution. Also, the second derivative of $l(\theta)$ is strictly negative for all θ ; hence, the solution is a maximum.

Having shown that the mle exists and is unique, we can use a numerical method to obtain the solution. In this case, Newton's procedure is useful. We discuss this in general in the next section, at which time we reconsider this example. ■

Example 6.1.3. In Example 4.1.2, we discussed the mle of the probability of success θ for a random sample X_1, X_2, \dots, X_n from the Bernoulli distribution with pmf

$$p(x) = \begin{cases} \theta^x (1 - \theta)^{1-x} & x = 0, 1 \\ 0 & \text{elsewhere,} \end{cases}$$

where $0 \leq \theta \leq 1$. Recall that the mle is \bar{X} , the proportion of sample successes. Now suppose that we know in advance that, instead of $0 \leq \theta \leq 1$, θ is restricted by the inequalities $0 \leq \theta \leq 1/3$. If the observations were such that $\bar{x} > 1/3$, then \bar{x} would not be a satisfactory estimate. Since $\frac{\partial l(\theta)}{\partial\theta} > 0$, provided $\theta < \bar{x}$, under the restriction $0 \leq \theta \leq 1/3$, we can maximize $l(\theta)$ by taking $\hat{\theta} = \min\{\bar{x}, \frac{1}{3}\}$. ■

The following is an appealing property of maximum likelihood estimates.

Theorem 6.1.2. Let X_1, \dots, X_n be iid with the pdf $f(x; \theta), \theta \in \Omega$. For a specified function g , let $\eta = g(\theta)$ be a parameter of interest. Suppose $\hat{\theta}$ is the mle of θ . Then $g(\hat{\theta})$ is the mle of $\eta = g(\theta)$.

Proof: First suppose g is a one-to-one function. The likelihood of interest is $L(g(\theta))$, but because g is one-to-one,

$$\max L(g(\theta)) = \max_{\eta=g(\theta)} L(\eta) = \max_{\eta} L(g^{-1}(\eta)).$$

But the maximum occurs when $g^{-1}(\eta) = \hat{\theta}$; i.e., take $\hat{\eta} = g(\hat{\theta})$.

Suppose g is not one-to-one. For each η in the range of g , define the set (preimage)

$$g^{-1}(\eta) = \{\theta : g(\theta) = \eta\}.$$

The maximum occurs at $\hat{\theta}$ and the domain of g is Ω , which covers $\hat{\theta}$. Hence, $\hat{\theta}$ is in one of these preimages and, in fact, it can only be in one preimage. Hence to maximize $L(\eta)$, choose $\hat{\eta}$ so that $g^{-1}(\hat{\eta})$ is that unique preimage containing $\hat{\theta}$. Then $\hat{\eta} = g(\hat{\theta})$. ■

Consider Example 4.1.2, where X_1, \dots, X_n are iid Bernoulli random variables with probability of success p . As shown in this example, $\hat{p} = \bar{X}$ is the mle of p . Recall that in the large sample confidence interval for p , (4.2.7), an estimate of $\sqrt{p(1-p)}$ is required. By Theorem 6.1.2, the mle of this quantity is $\sqrt{\hat{p}(1-\hat{p})}$.

We close this section by showing that maximum likelihood estimators, under regularity conditions, are consistent estimators. Recall that $\mathbf{X}' = (X_1, \dots, X_n)$.

Theorem 6.1.3. *Assume that X_1, \dots, X_n satisfy the regularity conditions (R0) through (R2), where θ_0 is the true parameter, and further that $f(x; \theta)$ is differentiable with respect to θ in Ω . Then the likelihood equation,*

$$\frac{\partial}{\partial \theta} L(\theta) = 0,$$

or equivalently

$$\frac{\partial}{\partial \theta} l(\theta) = 0,$$

has a solution $\hat{\theta}_n$ such that $\hat{\theta}_n \xrightarrow{P} \theta_0$.

Proof: Because θ_0 is an interior point in Ω , $(\theta_0 - a, \theta_0 + a) \subset \Omega$, for some $a > 0$. Define S_n to be the event

$$S_n = \{\mathbf{X} : l(\theta_0; \mathbf{X}) > l(\theta_0 - a; \mathbf{X})\} \cap \{\mathbf{X} : l(\theta_0; \mathbf{X}) > l(\theta_0 + a; \mathbf{X})\}.$$

By Theorem 6.1.1, $P(S_n) \rightarrow 1$. So we can restrict attention to the event S_n . But on S_n , $l(\theta)$ has a local maximum, say, $\hat{\theta}_n$, such that $\theta_0 - a < \hat{\theta}_n < \theta_0 + a$ and $l'(\hat{\theta}_n) = 0$. That is,

$$S_n \subset \left\{ \mathbf{X} : |\hat{\theta}_n(\mathbf{X}) - \theta_0| < a \right\} \cap \left\{ \mathbf{X} : l'(\hat{\theta}_n(\mathbf{X})) = 0 \right\}.$$

Therefore,

$$1 = \lim_{n \rightarrow \infty} P(S_n) \leq \overline{\lim}_{n \rightarrow \infty} P \left[\left\{ \mathbf{X} : |\hat{\theta}_n(\mathbf{X}) - \theta_0| < a \right\} \cap \left\{ \mathbf{X} : l'(\hat{\theta}_n(\mathbf{X})) = 0 \right\} \right] \leq 1;$$

see Remark 5.2.3 for discussion on $\overline{\lim}$. It follows that for the sequence of solutions $\hat{\theta}_n$, $P[|\hat{\theta}_n - \theta_0| < a] \rightarrow 1$.

The only contentious point in the proof is that the sequence of solutions might depend on a . But we can always choose a solution “closest” to θ_0 in the following way. For each n , the set of all solutions in the interval is bounded; hence, the infimum over solutions closest to θ_0 exists. ■

Note that this theorem is vague in that it discusses solutions of the equation. If, however, we know that the mle is the unique solution of the equation $l'(\theta) = 0$, then it is consistent. We state this as a corollary:

Corollary 6.1.1. *Assume that X_1, \dots, X_n satisfy the regularity conditions (R0) through (R2), where θ_0 is the true parameter, and that $f(x; \theta)$ is differentiable with respect to θ in Ω . Suppose the likelihood equation has the unique solution $\hat{\theta}_n$. Then $\hat{\theta}_n$ is a consistent estimator of θ_0 .*

EXERCISES

6.1.1. Let X_1, X_2, \dots, X_n be a random sample on X that has a $\Gamma(\alpha = 4, \beta = \theta)$ distribution, $0 < \theta < \infty$.

- (a) Determine the mle of θ .
- (b) Suppose the following data is a realization (rounded) of a random sample on X . Obtain a histogram with the argument `pr=T` (data are in `ex6111.rda`).

```
9 39 38 23 8 47 21 22 18 10 17 22 14
9 5 26 11 31 15 25 9 29 28 19 8
```

- (c) For this sample, obtain $\hat{\theta}$ the realized value of the mle and locate $4\hat{\theta}$ on the histogram. Overlay the $\Gamma(\alpha = 4, \beta = \hat{\theta})$ pdf on the histogram. Does the data agree with this pdf? Code for overlay:

```
xs=sort(x);y=dgamma(xs,4,1/betahat);hist(x,pr=T);lines(y~xs).
```

6.1.2. Let X_1, X_2, \dots, X_n represent a random sample from each of the distributions having the following pdfs:

- (a) $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, $0 < \theta < \infty$, zero elsewhere.
- (b) $f(x; \theta) = e^{-(x-\theta)}$, $\theta \leq x < \infty$, $-\infty < \theta < \infty$, zero elsewhere. Note that this is a nonregular case.

In each case find the mle $\hat{\theta}$ of θ .

6.1.3. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from a distribution with pdf $f(x; \theta) = 1$, $\theta - \frac{1}{2} \leq x \leq \theta + \frac{1}{2}$, $-\infty < \theta < \infty$, zero elsewhere. This is a nonregular case. Show that every statistic $u(X_1, X_2, \dots, X_n)$ such that

$$Y_n - \frac{1}{2} \leq u(X_1, X_2, \dots, X_n) \leq Y_1 + \frac{1}{2}$$

is a mle of θ . In particular, $(4Y_1 + 2Y_n + 1)/6$, $(Y_1 + Y_n)/2$, and $(2Y_1 + 4Y_n - 1)/6$ are three such statistics. Thus, uniqueness is not, in general, a property of mles.

6.1.4. Suppose X_1, \dots, X_n are iid with pdf $f(x; \theta) = 2x/\theta^2$, $0 < x \leq \theta$, zero elsewhere. Note this is a nonregular case. Find:

- (a) The mle $\hat{\theta}$ for θ .
- (b) The constant c so that $E(c\hat{\theta}) = \theta$.
- (c) The mle for the median of the distribution. Show that it is a consistent estimator.

6.1.5. Consider the pdf in Exercise 6.1.4.

- (a) Using Theorem 4.8.1, show how to generate observations from this pdf.
- (b) The following data were generated from this pdf. Find the mles of θ and the median.

$$\begin{array}{cccccccccc} 1.2 & 7.7 & 4.3 & 4.1 & 7.1 & 6.3 & 5.3 & 6.3 & 5.3 & 2.8 \\ 3.8 & 7.0 & 4.5 & 5.0 & 6.3 & 6.7 & 5.0 & 7.4 & 7.5 & 7.5 \end{array}$$

6.1.6. Suppose X_1, X_2, \dots, X_n are iid with pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, zero elsewhere. Find the mle of $P(X \leq 2)$ and show that it is consistent.

6.1.7. Let the table

x	0	1	2	3	4	5
Frequency	6	10	14	13	6	1

represent a summary of a sample of size 50 from a binomial distribution having $n = 5$. Find the mle of $P(X \geq 3)$. For the data in the table, using the R function `pbinom` determine the realization of the mle.

6.1.8. Let X_1, X_2, X_3, X_4, X_5 be a random sample from a Cauchy distribution with median θ , that is, with pdf

$$f(x; \theta) = \frac{1}{\pi} \frac{1}{1 + (x - \theta)^2}, \quad -\infty < x < \infty,$$

where $-\infty < \theta < \infty$. Suppose $x_1 = -1.94$, $x_2 = 0.59$, $x_3 = -5.98$, $x_4 = -0.08$, and $x_5 = -0.77$.

- (a) Show that the mle can be obtained by minimizing

$$\sum_{i=1}^5 \log[1 + (x_i - \theta)^2].$$

- (b) Approximate the mle by plotting the function in Part (a). Make use of the following R code which assumes that the data are in the R vector \mathbf{x} :

```
theta=seq(-6,6,.001);lfs<-c()
for(th in theta){lfs=c(lfs,sum(log((x-th)^2+1)))}
plot(lfs~theta)
```

- 6.1.9.** Let the table

x	0	1	2	3	4	5
Frequency	7	14	12	13	6	3

represent a summary of a random sample of size 55 from a Poisson distribution. Find the maximum likelihood estimator of $P(X = 2)$. Use the R function `dpois` to find the estimator's realization for the data in the table.

- 6.1.10.** Let X_1, X_2, \dots, X_n be a random sample from a Bernoulli distribution with parameter p . If p is restricted so that we know that $\frac{1}{2} \leq p \leq 1$, find the mle of this parameter.

- 6.1.11.** Let X_1, X_2, \dots, X_n be a random sample from a $N(\theta, \sigma^2)$ distribution, where σ^2 is fixed but $-\infty < \theta < \infty$.

- (a) Show that the mle of θ is \bar{X} .

- (b) If θ is restricted by $0 \leq \theta < \infty$, show that the mle of θ is $\hat{\theta} = \max\{0, \bar{X}\}$.

- 6.1.12.** Let X_1, X_2, \dots, X_n be a random sample from the Poisson distribution with $0 < \theta \leq 2$. Show that the mle of θ is $\hat{\theta} = \min\{\bar{X}, 2\}$.

- 6.1.13.** Let X_1, X_2, \dots, X_n be a random sample from a distribution with one of two pdfs. If $\theta = 1$, then $f(x; \theta = 1) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$, $-\infty < x < \infty$. If $\theta = 2$, then $f(x; \theta = 2) = 1/[\pi(1 + x^2)]$, $-\infty < x < \infty$. Find the mle of θ .

6.2 Rao–Cramér Lower Bound and Efficiency

In this section, we establish a remarkable inequality called the **Rao–Cramér** lower bound, which gives a lower bound on the variance of any unbiased estimate. We then show that, under regularity conditions, the variances of the maximum likelihood estimates achieve this lower bound asymptotically.

As in the last section, let X be a random variable with pdf $f(x; \theta)$, $\theta \in \Omega$, where the parameter space Ω is an open interval. In addition to the regularity conditions (6.1.1) of Section 6.1, for the following derivations, we require two more regularity conditions, namely,

Assumptions 6.2.1 (Additional Regularity Conditions). *Regularity conditions (R3) and (R4) are given by*

(R3) *The pdf $f(x; \theta)$ is twice differentiable as a function of θ .*

(R4) The integral $\int f(x; \theta) dx$ can be differentiated twice under the integral sign as a function of θ .

Note that conditions (R1)–(R4) mean that the parameter θ does not appear in the endpoints of the interval in which $f(x; \theta) > 0$ and that we can interchange integration and differentiation with respect to θ . Our derivation is for the continuous case, but the discrete case can be handled in a similar manner. We begin with the identity

$$1 = \int_{-\infty}^{\infty} f(x; \theta) dx.$$

Taking the derivative with respect to θ results in

$$0 = \int_{-\infty}^{\infty} \frac{\partial f(x; \theta)}{\partial \theta} dx.$$

The latter expression can be rewritten as

$$0 = \int_{-\infty}^{\infty} \frac{\partial \log f(x; \theta)/\partial \theta}{f(x; \theta)} f(x; \theta) dx,$$

or, equivalently,

$$0 = \int_{-\infty}^{\infty} \frac{\partial \log f(x; \theta)}{\partial \theta} f(x; \theta) dx. \quad (6.2.1)$$

Writing this last equation as an expectation, we have established

$$E \left[\frac{\partial \log f(X; \theta)}{\partial \theta} \right] = 0; \quad (6.2.2)$$

that is, the mean of the random variable $\frac{\partial \log f(X; \theta)}{\partial \theta}$ is 0. If we differentiate (6.2.1) again, it follows that

$$0 = \int_{-\infty}^{\infty} \frac{\partial^2 \log f(x; \theta)}{\partial \theta^2} f(x; \theta) dx + \int_{-\infty}^{\infty} \frac{\partial \log f(x; \theta)}{\partial \theta} \frac{\partial \log f(x; \theta)}{\partial \theta} f(x; \theta) dx. \quad (6.2.3)$$

The second term of the right side of this equation can be written as an expectation, which we call **Fisher information** and we denote it by $I(\theta)$; that is,

$$I(\theta) = \int_{-\infty}^{\infty} \frac{\partial \log f(x; \theta)}{\partial \theta} \frac{\partial \log f(x; \theta)}{\partial \theta} f(x; \theta) dx = E \left[\left(\frac{\partial \log f(X; \theta)}{\partial \theta} \right)^2 \right]. \quad (6.2.4)$$

From equation (6.2.3), we see that $I(\theta)$ can be computed from

$$I(\theta) = - \int_{-\infty}^{\infty} \frac{\partial^2 \log f(x; \theta)}{\partial \theta^2} f(x; \theta) dx = -E \left[\frac{\partial^2 \log f(X; \theta)}{\partial \theta^2} \right]. \quad (6.2.5)$$

Using equation (6.2.2), Fisher information is the variance of the random variable $\frac{\partial \log f(X; \theta)}{\partial \theta}$; i.e.,

$$I(\theta) = \text{Var} \left(\frac{\partial \log f(X; \theta)}{\partial \theta} \right). \quad (6.2.6)$$

Usually, expression (6.2.5) is easier to compute than expression (6.2.4).

Remark 6.2.1. Note that the information is the weighted mean of either

$$\left[\frac{\partial \log f(x; \theta)}{\partial \theta} \right]^2 \quad \text{or} \quad -\frac{\partial^2 \log f(x; \theta)}{\partial \theta^2},$$

where the weights are given by the pdf $f(x; \theta)$. That is, the greater these derivatives are on the average, the more information that we get about θ . Clearly, if they were equal to zero [so that θ would not be in $\log f(x; \theta)$], there would be zero information about θ . The important function

$$\frac{\partial \log f(x; \theta)}{\partial \theta}$$

is called the **score function**. Recall that it determines the estimating equations for the mle; that is, the mle $\hat{\theta}$ solves

$$\sum_{i=1}^n \frac{\partial \log f(x_i; \theta)}{\partial \theta} = 0$$

for θ . ■

Example 6.2.1 (Information for a Bernoulli Random Variable). Let X be Bernoulli $b(1, \theta)$. Thus

$$\begin{aligned} \log f(x; \theta) &= x \log \theta + (1-x) \log(1-\theta) \\ \frac{\partial \log f(x; \theta)}{\partial \theta} &= \frac{x}{\theta} - \frac{1-x}{1-\theta} \\ \frac{\partial^2 \log f(x; \theta)}{\partial \theta^2} &= -\frac{x}{\theta^2} - \frac{1-x}{(1-\theta)^2}. \end{aligned}$$

Clearly,

$$\begin{aligned} I(\theta) &= -E \left[\frac{-X}{\theta^2} - \frac{1-X}{(1-\theta)^2} \right] \\ &= \frac{\theta}{\theta^2} + \frac{1-\theta}{(1-\theta)^2} = \frac{1}{\theta} + \frac{1}{(1-\theta)} = \frac{1}{\theta(1-\theta)}, \end{aligned}$$

which is larger for θ values close to zero or one. ■

Example 6.2.2 (Information for a Location Family). Consider a random sample X_1, \dots, X_n such that

$$X_i = \theta + e_i, \quad i = 1, \dots, n, \tag{6.2.7}$$

where e_1, e_2, \dots, e_n are iid with common pdf $f(x)$ and with support $(-\infty, \infty)$. Then the common pdf of X_i is $f_X(x; \theta) = f(x - \theta)$. We call model (6.2.7) a **location model**. Assume that $f(x)$ satisfies the regularity conditions. Then the information is

$$\begin{aligned} I(\theta) &= \int_{-\infty}^{\infty} \left(\frac{f'(x - \theta)}{f(x - \theta)} \right)^2 f(x - \theta) dx \\ &= \int_{-\infty}^{\infty} \left(\frac{f'(z)}{f(z)} \right)^2 f(z) dz, \end{aligned} \tag{6.2.8}$$

where the last equality follows from the transformation $z = x - \theta$. Hence, in the location model, the information does not depend on θ .

As an illustration, reconsider Example 6.1.1 concerning the Laplace distribution. Let X_1, X_2, \dots, X_n be a random sample from this distribution. Then it follows that X_i can be expressed as

$$X_i = \theta + e_i, \quad (6.2.9)$$

where e_1, \dots, e_n are iid with common pdf $f(z) = 2^{-1} \exp\{-|z|\}$, for $-\infty < z < \infty$. As we did in Example 6.1.1, use $\frac{d}{dz}|z| = \text{sgn}(z)$. Then $f'(z) = -2^{-1}\text{sgn}(z)\exp\{-|z|\}$ and, hence, $[f'(z)/f(z)]^2 = [-\text{sgn}(z)]^2 = 1$, so that

$$I(\theta) = \int_{-\infty}^{\infty} \left(\frac{f'(z)}{f(z)} \right)^2 f(z) dz = \int_{-\infty}^{\infty} f(z) dz = 1. \quad (6.2.10)$$

Note that the Laplace pdf does not satisfy the regularity conditions, but this argument can be made rigorous; see Huber (1981) and also Chapter 10. ■

From (6.2.6), for a sample of size 1, say X_1 , Fisher information is the variance of the random variable $\frac{\partial \log f(X_1; \theta)}{\partial \theta}$. What about a sample of size n ? Let X_1, X_2, \dots, X_n be a random sample from a distribution having pdf $f(x; \theta)$. The likelihood $L(\theta)$ is the pdf of the random sample, and the random variable whose variance is the information in the sample is given by

$$\frac{\partial \log L(\theta, \mathbf{X})}{\partial \theta} = \sum_{i=1}^n \frac{\partial \log f(X_i; \theta)}{\partial \theta}.$$

The summands are iid with common variance $I(\theta)$. Hence the information in the sample is

$$\text{Var} \left(\frac{\partial \log L(\theta, \mathbf{X})}{\partial \theta} \right) = nI(\theta). \quad (6.2.11)$$

Thus the information in a random sample of size n is n times the information in a sample of size 1. So, in Example 6.2.1, the Fisher information in a random sample of size n from a Bernoulli $b(1, \theta)$ distribution is $n/[\theta(1 - \theta)]$.

We are now ready to obtain the Rao–Cramér lower bound, which we state as a theorem.

Theorem 6.2.1 (Rao–Cramér Lower Bound). *Let X_1, \dots, X_n be iid with common pdf $f(x; \theta)$ for $\theta \in \Omega$. Assume that the regularity conditions (R0)–(R4) hold. Let $Y = u(X_1, X_2, \dots, X_n)$ be a statistic with mean $E(Y) = E[u(X_1, X_2, \dots, X_n)] = k(\theta)$. Then*

$$\text{Var}(Y) \geq \frac{[k'(\theta)]^2}{nI(\theta)}. \quad (6.2.12)$$

Proof: The proof is for the continuous case, but the proof for the discrete case is quite similar. Write the mean of Y as

$$k(\theta) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} u(x_1, \dots, x_n) f(x_1; \theta) \cdots f(x_n; \theta) dx_1 \cdots dx_n.$$

Differentiating with respect to θ , we obtain

$$\begin{aligned}
 k'(\theta) &= \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} u(x_1, x_2, \dots, x_n) \left[\sum_1^n \frac{1}{f(x_i; \theta)} \frac{\partial f(x_i; \theta)}{\partial \theta} \right] \\
 &\quad \times f(x_1; \theta) \cdots f(x_n; \theta) dx_1 \cdots dx_n \\
 &= \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} u(x_1, x_2, \dots, x_n) \left[\sum_1^n \frac{\partial \log f(x_i; \theta)}{\partial \theta} \right] \\
 &\quad \times f(x_1; \theta) \cdots f(x_n; \theta) dx_1 \cdots dx_n. \tag{6.2.13}
 \end{aligned}$$

Define the random variable Z by $Z = \sum_1^n [\partial \log f(X_i; \theta) / \partial \theta]$. We know from (6.2.2) and (6.2.11) that $E(Z) = 0$ and $\text{Var}(Z) = nI(\theta)$, respectively. Also, equation (6.2.13) can be expressed in terms of expectation as $k'(\theta) = E(YZ)$. Hence we have

$$k'(\theta) = E(YZ) = E(Y)E(Z) + \rho\sigma_Y \sqrt{nI(\theta)},$$

where ρ is the correlation coefficient between Y and Z . Using $E(Z) = 0$, this simplifies to

$$\rho = \frac{k'(\theta)}{\sigma_Y \sqrt{nI(\theta)}}.$$

Because $\rho^2 \leq 1$, we have

$$\frac{[k'(\theta)]^2}{\sigma_Y^2 nI(\theta)} \leq 1,$$

which, upon rearrangement, is the desired result. ■

Corollary 6.2.1. *Under the assumptions of Theorem 6.2.1, if $Y = u(X_1, \dots, X_n)$ is an unbiased estimator of θ , so that $k(\theta) = \theta$, then the Rao–Cramér inequality becomes*

$$\text{Var}(Y) \geq \frac{1}{nI(\theta)}.$$

Consider the Bernoulli model with probability of success θ which was treated in Example 6.2.1. In the example we showed that $1/nI(\theta) = \theta(1-\theta)/n$. From Example 4.1.2 of Section 4.1, the mle of θ is \bar{X} . The mean and variance of a Bernoulli (θ) distribution are θ and $\theta(1-\theta)$, respectively. Hence the mean and variance of \bar{X} are θ and $\theta(1-\theta)/n$, respectively. That is, in this case the variance of the mle has attained the Rao–Cramér lower bound.

We now make the following definitions.

Definition 6.2.1 (Efficient Estimator). *Let Y be an unbiased estimator of a parameter θ in the case of point estimation. The statistic Y is called an **efficient estimator** of θ if and only if the variance of Y attains the Rao–Cramér lower bound.*

Definition 6.2.2 (Efficiency). *In cases in which we can differentiate with respect to a parameter under an integral or summation symbol, the ratio of the Rao–Cramér lower bound to the actual variance of any unbiased estimator of a parameter is called the efficiency of that estimator.*

Example 6.2.3 (Poisson(θ) Distribution). Let X_1, X_2, \dots, X_n denote a random sample from a Poisson distribution that has the mean $\theta > 0$. It is known that \bar{X} is an mle of θ ; we shall show that it is also an efficient estimator of θ . We have

$$\begin{aligned}\frac{\partial \log f(x; \theta)}{\partial \theta} &= \frac{\partial}{\partial \theta}(x \log \theta - \theta - \log x!) \\ &= \frac{x}{\theta} - 1 = \frac{x - \theta}{\theta}.\end{aligned}$$

Accordingly,

$$E\left[\left(\frac{\partial \log f(X; \theta)}{\partial \theta}\right)^2\right] = \frac{E(X - \theta)^2}{\theta^2} = \frac{\sigma^2}{\theta^2} = \frac{\theta}{\theta^2} = \frac{1}{\theta}.$$

The Rao–Cramér lower bound in this case is $1/[n(1/\theta)] = \theta/n$. But θ/n is the variance of \bar{X} . Hence \bar{X} is an efficient estimator of θ . ■

Example 6.2.4 (Beta($\theta, 1$) Distribution). Let X_1, X_2, \dots, X_n denote a random sample of size $n > 2$ from a distribution with pdf

$$f(x; \theta) = \begin{cases} \theta x^{\theta-1} & \text{for } 0 < x < 1 \\ 0 & \text{elsewhere,} \end{cases} \quad (6.2.14)$$

where the parameter space is $\Omega = (0, \infty)$. This is the beta distribution, (3.3.9), with parameters θ and 1, which we denote by $\text{beta}(\theta, 1)$. The derivative of the log of f is

$$\frac{\partial \log f}{\partial \theta} = \log x + \frac{1}{\theta}. \quad (6.2.15)$$

From this we have $\partial^2 \log f / \partial \theta^2 = -\theta^{-2}$. Hence the information is $I(\theta) = \theta^{-2}$.

Next, we find the mle of θ and investigate its efficiency. The log of the likelihood function is

$$l(\theta) = \theta \sum_{i=1}^n \log x_i - \sum_{i=1}^n \log x_i + n \log \theta.$$

The first partial of $l(\theta)$ is

$$\frac{\partial l(\theta)}{\partial \theta} = \sum_{i=1}^n \log x_i + \frac{n}{\theta}. \quad (6.2.16)$$

Setting this to 0 and solving for θ , the mle is $\hat{\theta} = -n / \sum_{i=1}^n \log X_i$. To obtain the distribution of $\hat{\theta}$, let $Y_i = -\log X_i$. A straight transformation argument shows

that the distribution is $\Gamma(1, 1/\theta)$. Because the X_i s are independent, Theorem 3.3.1 shows that $W = \sum_{i=1}^n Y_i$ is $\Gamma(n, 1/\theta)$. Theorem 3.3.2 shows that

$$E[W^k] = \frac{(n+k-1)!}{\theta^k (n-1)!}, \quad (6.2.17)$$

for $k > -n$. So, in particular for $k = -1$, we get

$$E[\hat{\theta}] = nE[W^{-1}] = \theta \frac{n}{n-1}.$$

Hence, $\hat{\theta}$ is biased, but the bias vanishes as $n \rightarrow \infty$. Also, note that the estimator $[(n-1)/n]\hat{\theta}$ is unbiased. For $k = -2$, we get

$$E[\hat{\theta}^2] = n^2 E[W^{-2}] = \theta^2 \frac{n^2}{(n-1)(n-2)},$$

and, hence, after simplifying $E(\hat{\theta}^2) - [E(\hat{\theta})]^2$, we obtain

$$\text{Var}(\hat{\theta}) = \theta^2 \frac{n^2}{(n-1)^2(n-2)}.$$

From this, we can obtain the variance of the unbiased estimator $[(n-1)/n]\hat{\theta}$, i.e.,

$$\text{Var}\left(\frac{n-1}{n}\hat{\theta}\right) = \frac{\theta^2}{n-2}.$$

From above, the information is $I(\theta) = \theta^{-2}$ and, hence, the variance of an unbiased efficient estimator is θ^2/n . Because $\frac{\theta^2}{n-2} > \frac{\theta^2}{n}$, the unbiased estimator $[(n-1)/n]\hat{\theta}$ is not efficient. Notice, though, that its efficiency (as in Definition 6.2.2) converges to 1 as $n \rightarrow \infty$. Later in this section, we say that $[(n-1)/n]\hat{\theta}$ is asymptotically efficient. ■

In the above examples, we were able to obtain the mles in closed form along with their distributions and, hence, moments. This is often not the case. Maximum likelihood estimators, however, have an asymptotic normal distribution. In fact, mles are asymptotically efficient. To prove these assertions, we need the additional regularity condition given by

Assumptions 6.2.2 (Additional Regularity Condition). *Regularity condition (R5) is*

(R5) *The pdf $f(x; \theta)$ is three times differentiable as a function of θ . Further, for all $\theta \in \Omega$, there exist a constant c and a function $M(x)$ such that*

$$\left| \frac{\partial^3}{\partial \theta^3} \log f(x; \theta) \right| \leq M(x),$$

with $E_{\theta_0}[M(X)] < \infty$, for all $\theta_0 - c < \theta < \theta_0 + c$ and all x in the support of X .

Theorem 6.2.2. Assume X_1, \dots, X_n are iid with pdf $f(x; \theta_0)$ for $\theta_0 \in \Omega$ such that the regularity conditions (R0)–(R5) are satisfied. Suppose further that the Fisher information satisfies $0 < I(\theta_0) < \infty$. Then any consistent sequence of solutions of the mle equations satisfies

$$\sqrt{n}(\hat{\theta} - \theta_0) \xrightarrow{D} N\left(0, \frac{1}{I(\theta_0)}\right). \quad (6.2.18)$$

Proof: Expanding the function $l'(\theta)$ into a Taylor series of order 2 about θ_0 and evaluating it at $\hat{\theta}_n$, we get

$$l'(\hat{\theta}_n) = l'(\theta_0) + (\hat{\theta}_n - \theta_0)l''(\theta_0) + \frac{1}{2}(\hat{\theta}_n - \theta_0)^2 l'''(\theta_n^*), \quad (6.2.19)$$

where θ_n^* is between θ_0 and $\hat{\theta}_n$. But $l'(\hat{\theta}_n) = 0$. Hence, rearranging terms, we obtain

$$\sqrt{n}(\hat{\theta}_n - \theta_0) = \frac{n^{-1/2}l'(\theta_0)}{-n^{-1}l''(\theta_0) - (2n)^{-1}(\hat{\theta}_n - \theta_0)l'''(\theta_n^*)}. \quad (6.2.20)$$

By the Central Limit Theorem,

$$\frac{1}{\sqrt{n}}l'(\theta_0) = \frac{1}{\sqrt{n}} \sum_{i=1}^n \frac{\partial \log f(X_i; \theta_0)}{\partial \theta} \xrightarrow{D} N(0, I(\theta_0)), \quad (6.2.21)$$

because the summands are iid with $\text{Var}(\partial \log f(X_i; \theta_0)/\partial \theta) = I(\theta_0) < \infty$. Also, by the Law of Large Numbers,

$$-\frac{1}{n}l''(\theta_0) = -\frac{1}{n} \sum_{i=1}^n \frac{\partial^2 \log f(X_i; \theta_0)}{\partial \theta^2} \xrightarrow{P} I(\theta_0). \quad (6.2.22)$$

To complete the proof then, we need only show that the second term in the denominator of expression (6.2.20) goes to zero in probability. Because $\hat{\theta}_n - \theta_0 \xrightarrow{P} 0$ by Theorem 5.2.7, this follows provided that $n^{-1}l'''(\theta_n^*)$ is bounded in probability. Let c_0 be the constant defined in condition (R5). Note that $|\hat{\theta}_n - \theta_0| < c_0$ implies that $|\theta_n^* - \theta_0| < c_0$, which in turn by condition (R5) implies the following string of inequalities:

$$\left| -\frac{1}{n}l'''(\theta_n^*) \right| \leq \frac{1}{n} \sum_{i=1}^n \left| \frac{\partial^3 \log f(X_i; \theta)}{\partial \theta^3} \right| \leq \frac{1}{n} \sum_{i=1}^n M(X_i). \quad (6.2.23)$$

By condition (R5), $E_{\theta_0}[M(X)] < \infty$; hence, $\frac{1}{n} \sum_{i=1}^n M(X_i) \xrightarrow{P} E_{\theta_0}[M(X)]$, by the Law of Large Numbers. For the bound, we select $1 + E_{\theta_0}[M(X)]$. Let $\epsilon > 0$ be given. Choose N_1 and N_2 so that

$$n \geq N_1 \Rightarrow P[|\hat{\theta}_n - \theta_0| < c_0] \geq 1 - \frac{\epsilon}{2} \quad (6.2.24)$$

$$n \geq N_2 \Rightarrow P \left[\left| \frac{1}{n} \sum_{i=1}^n M(X_i) - E_{\theta_0}[M(X)] \right| < 1 \right] \geq 1 - \frac{\epsilon}{2}. \quad (6.2.25)$$

It follows from (6.2.23)–(6.2.25) that

$$n \geq \max\{N_1, N_2\} \Rightarrow P \left[\left| -\frac{1}{n} l'''(\theta_n^*) \right| \leq 1 + E_{\theta_0}[M(X)] \right] \geq 1 - \frac{\epsilon}{2};$$

hence, $n^{-1}l'''(\theta_n^*)$ is bounded in probability. ■

We next generalize Definitions 6.2.1 and 6.2.2 concerning efficiency to the asymptotic case.

Definition 6.2.3. Let X_1, \dots, X_n be independent and identically distributed with probability density function $f(x; \theta)$. Suppose $\hat{\theta}_{1n} = \hat{\theta}_{1n}(X_1, \dots, X_n)$ is an estimator of θ_0 such that $\sqrt{n}(\hat{\theta}_{1n} - \theta_0) \xrightarrow{D} N(0, \sigma_{\hat{\theta}_{1n}}^2)$. Then

(a) *The asymptotic efficiency of $\hat{\theta}_{1n}$ is defined to be*

$$e(\hat{\theta}_{1n}) = \frac{1/I(\theta_0)}{\sigma_{\hat{\theta}_{1n}}^2}. \quad (6.2.26)$$

(b) *The estimator $\hat{\theta}_{1n}$ is said to be **asymptotically efficient** if the ratio in part (a) is 1.*

(c) *Let $\hat{\theta}_{2n}$ be another estimator such that $\sqrt{n}(\hat{\theta}_{2n} - \theta_0) \xrightarrow{D} N(0, \sigma_{\hat{\theta}_{2n}}^2)$. Then the **asymptotic relative efficiency (ARE)** of $\hat{\theta}_{1n}$ to $\hat{\theta}_{2n}$ is the reciprocal of the ratio of their respective asymptotic variances; i.e.,*

$$e(\hat{\theta}_{1n}, \hat{\theta}_{2n}) = \frac{\sigma_{\hat{\theta}_{2n}}^2}{\sigma_{\hat{\theta}_{1n}}^2}. \quad (6.2.27)$$

Hence, by Theorem 6.2.2, under regularity conditions, maximum likelihood estimators are asymptotically efficient estimators. This is a nice optimality result. Also, if two estimators are asymptotically normal with the same asymptotic mean, then intuitively the estimator with the smaller asymptotic variance would be selected over the other as a better estimator. In this case, the ARE of the selected estimator to the nonselected one is greater than 1.

Example 6.2.5 (ARE of the Sample Median to the Sample Mean). We obtain this ARE under the Laplace and normal distributions. Consider first the Laplace location model as given in expression (6.2.9); i.e.,

$$X_i = \theta + e_i, \quad i = 1, \dots, n. \quad (6.2.28)$$

By Example 6.1.1, we know that the mle of θ is the sample median, Q_2 . By (6.2.10), the information $I(\theta_0) = 1$ for this distribution; hence, Q_2 is asymptotically normal with mean θ and variance $1/n$. On the other hand, by the Central Limit Theorem,

the sample mean \bar{X} is asymptotically normal with mean θ and variance σ^2/n , where $\sigma^2 = \text{Var}(X_i) = \text{Var}(e_i + \theta) = \text{Var}(e_i) = E(e_i^2)$. But

$$E(e_i^2) = \int_{-\infty}^{\infty} z^2 2^{-1} \exp\{-|z|\} dz = \int_0^{\infty} z^{3-1} \exp\{-z\} dz = \Gamma(3) = 2.$$

Therefore, the $\text{ARE}(Q_2, \bar{X}) = \frac{2}{1} = 2$. Thus, if the sample comes from a Laplace distribution, then asymptotically the sample median is twice as efficient as the sample mean.

Next suppose the location model (6.2.28) holds, except now the pdf of e_i is $N(0, 1)$. Under this model, by Theorem 10.2.3, Q_2 is asymptotically normal with mean θ and variance $(\pi/2)/n$. Because the variance of \bar{X} is $1/n$, in this case, the $\text{ARE}(Q_2, \bar{X}) = \frac{1}{\pi/2} = 2/\pi = 0.636$. Since $\pi/2 = 1.57$, asymptotically, \bar{X} is 1.57 times more efficient than Q_2 if the sample arises from the normal distribution. ■

Theorem 6.2.2 is also a practical result in that it gives us a way of doing inference. The asymptotic standard deviation of the mle $\hat{\theta}$ is $[nI(\theta_0)]^{-1/2}$. Because $I(\theta)$ is a continuous function of θ , it follows from Theorems 5.1.4 and 6.1.2 that

$$I(\hat{\theta}_n) \xrightarrow{P} I(\theta_0).$$

Thus we have a consistent estimate of the asymptotic standard deviation of the mle. Based on this result and the discussion of confidence intervals in Chapter 4, for a specified $0 < \alpha < 1$, the following interval is an approximate $(1 - \alpha)100\%$ confidence interval for θ ,

$$\left(\hat{\theta}_n - z_{\alpha/2} \frac{1}{\sqrt{nI(\hat{\theta}_n)}}, \hat{\theta}_n + z_{\alpha/2} \frac{1}{\sqrt{nI(\hat{\theta}_n)}} \right). \quad (6.2.29)$$

Remark 6.2.2. If we use the asymptotic distributions to construct confidence intervals for θ , the fact that the $\text{ARE}(Q_2, \bar{X}) = 2$ when the underlying distribution is the Laplace means that n would need to be twice as large for \bar{X} to get the same length confidence interval as we would if we used Q_2 . ■

A simple corollary to Theorem 6.2.2 yields the asymptotic distribution of a function $g(\hat{\theta}_n)$ of the mle.

Corollary 6.2.2. *Under the assumptions of Theorem 6.2.2, suppose $g(x)$ is a continuous function of x that is differentiable at θ_0 such that $g'(\theta_0) \neq 0$. Then*

$$\sqrt{n}(g(\hat{\theta}_n) - g(\theta_0)) \xrightarrow{D} N\left(0, \frac{g'(\theta_0)^2}{I(\theta_0)}\right). \quad (6.2.30)$$

The proof of this corollary follows immediately from the Δ -method, Theorem 5.2.9, and Theorem 6.2.2.

The proof of Theorem 6.2.2 contains an asymptotic representation of $\hat{\theta}$ which proves useful; hence, we state it as another corollary.

Corollary 6.2.3. *Under the assumptions of Theorem 6.2.2,*

$$\sqrt{n}(\hat{\theta}_n - \theta_0) = \frac{1}{I(\theta_0)} \frac{1}{\sqrt{n}} \sum_{i=1}^n \frac{\partial \log f(X_i; \theta_0)}{\partial \theta} + R_n, \quad (6.2.31)$$

where $R_n \xrightarrow{P} 0$.

The proof is just a rearrangement of equation (6.2.20) and the ensuing results in the proof of Theorem 6.2.2.

Example 6.2.6 (Example 6.2.4, Continued). Let X_1, \dots, X_n be a random sample having the common pdf (6.2.14). Recall that $I(\theta) = \theta^{-2}$ and that the mle is $\hat{\theta} = -n / \sum_{i=1}^n \log X_i$. Hence, $\hat{\theta}$ is approximately normally distributed with mean θ and variance θ^2/n . Based on this, an approximate $(1 - \alpha)100\%$ confidence interval for θ is

$$\hat{\theta} \pm z_{\alpha/2} \frac{\hat{\theta}}{\sqrt{n}}.$$

Recall that we were able to obtain the exact distribution of $\hat{\theta}$ in this case. As Exercise 6.2.12 shows, based on this distribution of $\hat{\theta}$, an exact confidence interval for θ can be constructed. ■

In obtaining the mle of θ , we are often in the situation of Example 6.1.2; that is, we can verify the existence of the mle, but the solution of the equation $l'(\hat{\theta}) = 0$ cannot be obtained in closed form. In such situations, numerical methods are used. One iterative method that exhibits rapid (quadratic) convergence is Newton's method. The sketch in Figure 6.2.1 helps recall this method. Suppose $\hat{\theta}^{(0)}$ is an initial guess at the solution. The next guess (one-step estimate) is the point $\hat{\theta}^{(1)}$, which is the horizontal intercept of the tangent line to the curve $l'(\theta)$ at the point $(\hat{\theta}^{(0)}, l'(\hat{\theta}^{(0)}))$. A little algebra finds

$$\hat{\theta}^{(1)} = \hat{\theta}^{(0)} - \frac{l'(\hat{\theta}^{(0)})}{l''(\hat{\theta}^{(0)})}. \quad (6.2.32)$$

We then substitute $\hat{\theta}^{(1)}$ for $\hat{\theta}^{(0)}$ and repeat the process. On the figure, trace the second step estimate $\hat{\theta}^{(2)}$; the process is continued until convergence.

Example 6.2.7 (Example 6.1.2, continued). Recall Example 6.1.2, where the random sample X_1, \dots, X_n has the common logistic density

$$f(x; \theta) = \frac{\exp\{-(x - \theta)\}}{(1 + \exp\{-(x - \theta)\})^2}, \quad -\infty < x < \infty, \quad -\infty < \theta < \infty. \quad (6.2.33)$$

We showed that the likelihood equation has a unique solution, though it cannot be obtained in closed form. To use formula (6.2.32), we need the first and second partial derivatives of $l(\theta)$ and an initial guess. Expression (6.1.9) of Example 6.1.2 gives the first partial derivative, from which the second partial is

$$l''(\theta) = -2 \sum_{i=1}^n \frac{\exp\{-(x_i - \theta)\}}{(1 + \exp\{-(x_i - \theta)\})^2}.$$

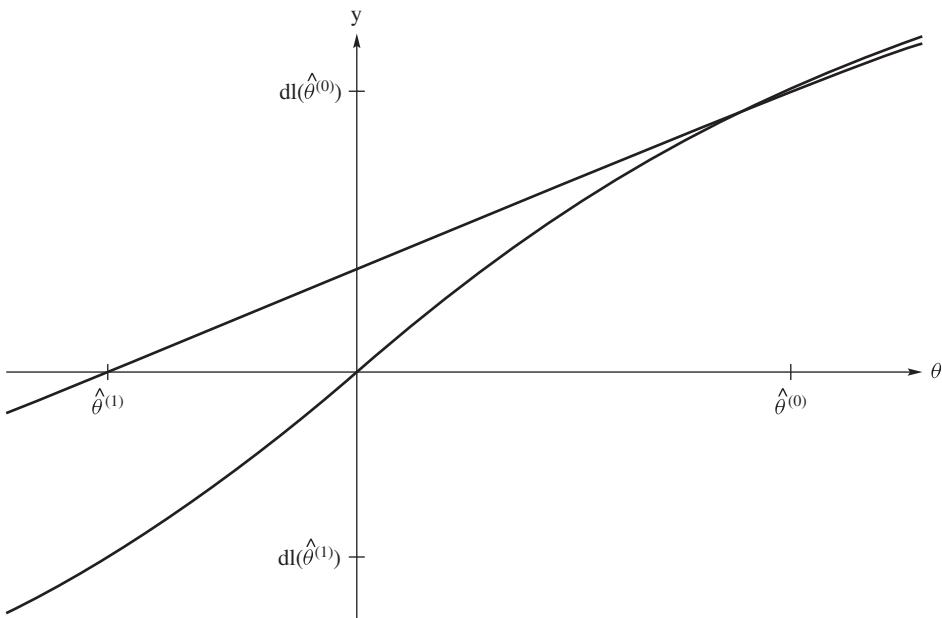

Figure 6.2.1: Beginning with the starting value $\hat{\theta}^{(0)}$, the one-step estimate is $\hat{\theta}^{(1)}$, which is the intersection of the tangent line to the curve $l'(\theta)$ at $\hat{\theta}^{(0)}$ and the horizontal axis. In the figure, $dl(\theta) = l'(\theta)$.

The logistic distribution is similar to the normal distribution; hence, we can use \bar{X} as our initial guess of θ . The R function `mlelogistic`, at the site listed in the preface, computes the k -step estimates. ■

We close this section with a remarkable fact. The estimate $\hat{\theta}^{(1)}$ in equation (6.2.32) is called the **one-step estimator**. As Exercise 6.2.15 shows, this estimator has the same asymptotic distribution as the mle [i.e., (6.2.18)], provided that the initial guess $\hat{\theta}^{(0)}$ is a consistent estimator of θ . That is, the one-step estimate is an asymptotically efficient estimate of θ . This is also true of the other iterative steps.

EXERCISES

6.2.1. Prove that \bar{X} , the mean of a random sample of size n from a distribution that is $N(\theta, \sigma^2)$, $-\infty < \theta < \infty$, is, for every known $\sigma^2 > 0$, an efficient estimator of θ .

6.2.2. Given $f(x; \theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere, with $\theta > 0$, formally compute the reciprocal of

$$nE \left\{ \left[\frac{\partial \log f(X : \theta)}{\partial \theta} \right]^2 \right\}.$$

Compare this with the variance of $(n+1)Y_n/n$, where Y_n is the largest observation of a random sample of size n from this distribution. Comment.

6.2.3. Given the pdf

$$f(x; \theta) = \frac{1}{\pi[1 + (x - \theta)^2]}, \quad -\infty < x < \infty, \quad -\infty < \theta < \infty,$$

show that the Rao–Cramér lower bound is $2/n$, where n is the size of a random sample from this Cauchy distribution. What is the asymptotic distribution of $\sqrt{n}(\hat{\theta} - \theta)$ if $\hat{\theta}$ is the mle of θ ?

6.2.4. Consider Example 6.2.2, where we discussed the location model.

- (a) Write the location model when e_i has the logistic pdf given in expression (4.4.11).
- (b) Using expression (6.2.8), show that the information $I(\theta) = 1/3$ for the model in part (a). *Hint:* In the integral of expression (6.2.8), use the substitution $u = (1 + e^{-z})^{-1}$. Then $du = f(z)dz$, where $f(z)$ is the pdf (4.4.11).

6.2.5. Using the same location model as in part (a) of Exercise 6.2.4, obtain the ARE of the sample median to mle of the model.

Hint: The mle of θ for this model is discussed in Example 6.2.7. Furthermore, as shown in Theorem 10.2.3 of Chapter 10, Q_2 is asymptotically normal with asymptotic mean θ and asymptotic variance $1/(4f^2(0)n)$.

6.2.6. Consider a location model (Example 6.2.2) when the error pdf is the contaminated normal (3.4.17) with ϵ as the proportion of contamination and with σ_c^2 as the variance of the contaminated part. Show that the ARE of the sample median to the sample mean is given by

$$e(Q_2, \bar{X}) = \frac{2[1 + \epsilon(\sigma_c^2 - 1)][1 - \epsilon + (\epsilon/\sigma_c)]^2}{\pi}. \quad (6.2.34)$$

Use the hint in Exercise 6.2.5 for the median.

- (a) If $\sigma_c^2 = 9$, use (6.2.34) to fill in the following table:

ϵ	0	0.05	0.10	0.15
$e(Q_2, \bar{X})$				

- (b) Notice from the table that the sample median becomes the “better” estimator when ϵ increases from 0.10 to 0.15. Determine the value for ϵ where this occurs [this involves a third-degree polynomial in ϵ , so one way of obtaining the root is to use the Newton algorithm discussed around expression (6.2.32)].

6.2.7. Recall Exercise 6.1.1 where X_1, X_2, \dots, X_n is a random sample on X that has a $\Gamma(\alpha = 4, \beta = \theta)$ distribution, $0 < \theta < \infty$.

- (a) Find the Fisher information $I(\theta)$.
- (b) Show that the mle of θ , which was derived in Exercise 6.1.1, is an efficient estimator of θ .
- (c) Using Theorem 6.2.2, obtain the asymptotic distribution of $\sqrt{n}(\hat{\theta} - \theta)$.
- (d) For the data of Example 6.1.1, find the asymptotic 95% confidence interval for θ .

6.2.8. Let X be $N(0, \theta)$, $0 < \theta < \infty$.

- (a) Find the Fisher information $I(\theta)$.
- (b) If X_1, X_2, \dots, X_n is a random sample from this distribution, show that the mle of θ is an efficient estimator of θ .
- (c) What is the asymptotic distribution of $\sqrt{n}(\hat{\theta} - \theta)$?

6.2.9. If X_1, X_2, \dots, X_n is a random sample from a distribution with pdf

$$f(x; \theta) = \begin{cases} \frac{3\theta^3}{(x+\theta)^4} & 0 < x < \infty, 0 < \theta < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

show that $Y = 2\bar{X}$ is an unbiased estimator of θ and determine its efficiency.

6.2.10. Let X_1, X_2, \dots, X_n be a random sample from a $N(0, \theta)$ distribution. We want to estimate the standard deviation $\sqrt{\theta}$. Find the constant c so that $Y = c \sum_{i=1}^n |X_i|$ is an unbiased estimator of $\sqrt{\theta}$ and determine its efficiency.

6.2.11. Let \bar{X} be the mean of a random sample of size n from a $N(\theta, \sigma^2)$ distribution, $-\infty < \theta < \infty, \sigma^2 > 0$. Assume that σ^2 is known. Show that $\bar{X}^2 - \frac{\sigma^2}{n}$ is an unbiased estimator of θ^2 and find its efficiency.

6.2.12. Recall that $\hat{\theta} = -n / \sum_{i=1}^n \log X_i$ is the mle of θ for a beta($\theta, 1$) distribution. Also, $W = -\sum_{i=1}^n \log X_i$ has the gamma distribution $\Gamma(n, 1/\theta)$.

- (a) Show that $2\theta W$ has a $\chi^2(2n)$ distribution.
- (b) Using part (a), find c_1 and c_2 so that

$$P\left(c_1 < \frac{2\theta n}{\hat{\theta}} < c_2\right) = 1 - \alpha, \quad (6.2.35)$$

for $0 < \alpha < 1$. Next, obtain a $(1 - \alpha)100\%$ confidence interval for θ .

- (c) For $\alpha = 0.05$ and $n = 10$, compare the length of this interval with the length of the interval found in Example 6.2.6.

6.2.13. The data file `beta30.rda` contains 30 observations generated from a beta($\theta, 1$) distribution, where $\theta = 4$. The file can be downloaded at the site discussed in the Preface.

- (a) Obtain a histogram of the data using the argument `pr=T`. Overlay the pdf of a $\beta(4, 1)$ pdf. Comment.
- (b) Using the results of Exercise 6.2.12, compute the maximum likelihood estimate based on the data.
- (c) Using the confidence interval found in Part (c) of Exercise 6.2.12, compute the 95% confidence interval for θ based on the data. Is the confidence interval successful?

6.2.14. Consider sampling on the random variable X with the pdf given in Exercise 6.2.9.

- (a) Obtain the corresponding cdf and its inverse. Show how to generate observations from this distribution.
- (b) Write an R function that generates a sample on X .
- (c) Generate a sample of size 50 and compute the unbiased estimate of θ discussed in Exercise 6.2.9. Use it and the Central Limit Theorem to compute a 95% confidence interval for θ .

6.2.15. By using expressions (6.2.21) and (6.2.22), obtain the result for the one-step estimate discussed at the end of this section.

6.2.16. Let S^2 be the sample variance of a random sample of size $n > 1$ from $N(\mu, \theta)$, $0 < \theta < \infty$, where μ is known. We know $E(S^2) = \theta$.

- (a) What is the efficiency of S^2 ?
- (b) Under these conditions, what is the mle $\hat{\theta}$ of θ ?
- (c) What is the asymptotic distribution of $\sqrt{n}(\hat{\theta} - \theta)$?

6.3 Maximum Likelihood Tests

In the last section, we presented an inference for pointwise estimation and confidence intervals based on likelihood theory. In this section, we present a corresponding inference for testing hypotheses.

As in the last section, let X_1, \dots, X_n be iid with pdf $f(x; \theta)$ for $\theta \in \Omega$. In this section, θ is a scalar, but in Sections 6.4 and 6.5 extensions to the vector-valued case are discussed. Consider the two-sided hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta \neq \theta_0, \quad (6.3.1)$$

where θ_0 is a specified value.

Recall that the likelihood function and its log are given by

$$\begin{aligned} L(\theta) &= \prod_{i=1}^n f(X_i; \theta) \\ l(\theta) &= \sum_{i=1}^n \log f(X_i; \theta). \end{aligned}$$

Let $\hat{\theta}$ denote the maximum likelihood estimate of θ .

To motivate the test, consider Theorem 6.1.1, which says that if θ_0 is the true value of θ , then, asymptotically, $L(\theta_0)$ is the maximum value of $L(\theta)$. Consider the ratio of two likelihood functions, namely,

$$\Lambda = \frac{L(\theta_0)}{L(\hat{\theta})}. \quad (6.3.2)$$

Note that $\Lambda \leq 1$, but if H_0 is true, Λ should be large (close to 1), while if H_1 is true, Λ should be smaller. For a specified significance level α , this leads to the intuitive decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \Lambda \leq c, \quad (6.3.3)$$

where c is such that $\alpha = P_{\theta_0}[\Lambda \leq c]$. We call it the **likelihood ratio test** (LRT). Theorem 6.3.1 derives the asymptotic distribution of Λ under H_0 , but first we look at two examples.

Example 6.3.1 (Likelihood Ratio Test for the Exponential Distribution). Suppose X_1, \dots, X_n are iid with pdf $f(x; \theta) = \theta^{-1} \exp\{-x/\theta\}$, for $x, \theta > 0$. Let the hypotheses be given by (6.3.1). The likelihood function simplifies to

$$L(\theta) = \theta^{-n} \exp\{-(n/\theta)\bar{X}\}.$$

From Example 4.1.1, the mle of θ is \bar{X} . After some simplification, the likelihood ratio test statistic simplifies to

$$\Lambda = e^n \left(\frac{\bar{X}}{\theta_0} \right)^n \exp\{-n\bar{X}/\theta_0\}. \quad (6.3.4)$$

The decision rule is to reject H_0 if $\Lambda \leq c$. But further simplification of the test is possible. Other than the constant e^n , the test statistic is of the form

$$g(t) = t^n \exp\{-nt\}, \quad t > 0,$$

where $t = \bar{x}/\theta_0$. Using differentiable calculus, it is easy to show that $g(t)$ has a unique critical value at 1, i.e., $g'(1) = 0$, and further that $t = 1$ provides a maximum, because $g''(1) < 0$. As Figure 6.3.1 depicts, $g(t) \leq c$ if and only if $t \leq c_1$ or $t \geq c_2$. This leads to

$$\Lambda \leq c, \text{ if and only if, } \frac{\bar{X}}{\theta_0} \leq c_1 \text{ or } \frac{\bar{X}}{\theta_0} \geq c_2.$$

Note that under the null hypothesis, H_0 , the statistic $(2/\theta_0) \sum_{i=1}^n X_i$ has a χ^2 distribution with $2n$ degrees of freedom. Based on this, the following decision rule results in a level α test:

$$\text{Reject } H_0 \text{ if } (2/\theta_0) \sum_{i=1}^n X_i \leq \chi_{1-\alpha/2}^2(2n) \text{ or } (2/\theta_0) \sum_{i=1}^n X_i \geq \chi_{\alpha/2}^2(2n), \quad (6.3.5)$$

where $\chi_{1-\alpha/2}^2(2n)$ is the lower $\alpha/2$ quantile of a χ^2 distribution with $2n$ degrees of freedom and $\chi_{\alpha/2}^2(2n)$ is the upper $\alpha/2$ quantile of a χ^2 distribution with $2n$ degrees of freedom. Other choices of c_1 and c_2 can be made, but these are usually the choices used in practice. Exercise 6.3.2 investigates the power curve for this test. ■

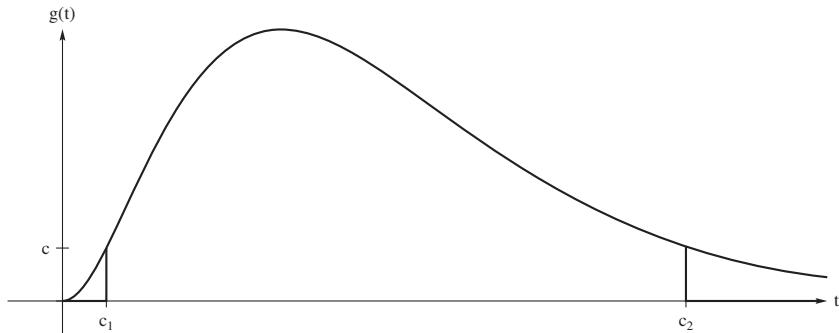

Figure 6.3.1: Plot for Example 6.3.1, showing that the function $g(t) \leq c$ if and only if $t \leq c_1$ or $t \geq c_2$.

Example 6.3.2 (Likelihood Ratio Test for the Mean of a Normal pdf). Consider a random sample X_1, X_2, \dots, X_n from a $N(\theta, \sigma^2)$ distribution where $-\infty < \theta < \infty$ and $\sigma^2 > 0$ is known. Consider the hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta \neq \theta_0,$$

where θ_0 is specified. The likelihood function is

$$\begin{aligned} L(\theta) &= \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \exp \left\{ -(2\sigma^2)^{-1} \sum_{i=1}^n (x_i - \theta)^2 \right\} \\ &= \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \exp \left\{ -(2\sigma^2)^{-1} \sum_{i=1}^n (x_i - \bar{x})^2 \right\} \exp \{ -(2\sigma^2)^{-1} n(\bar{x} - \theta)^2 \}. \end{aligned}$$

Of course, in $\Omega = \{\theta : -\infty < \theta < \infty\}$, the mle is $\hat{\theta} = \bar{X}$ and thus

$$\Lambda = \frac{L(\theta_0)}{L(\hat{\theta})} = \exp \{ -(2\sigma^2)^{-1} n(\bar{X} - \theta_0)^2 \}.$$

Then $\Lambda \leq c$ is equivalent to $-2 \log \Lambda \geq -2 \log c$. However,

$$-2 \log \Lambda = \left(\frac{\bar{X} - \theta_0}{\sigma/\sqrt{n}} \right)^2,$$

which has a $\chi^2(1)$ distribution under H_0 . Thus, the likelihood ratio test with significance level α states that we reject H_0 and accept H_1 when

$$-2 \log \Lambda = \left(\frac{\bar{X} - \theta_0}{\sigma/\sqrt{n}} \right)^2 \geq \chi_{\alpha}^2(1). \quad (6.3.6)$$

Note that this test is the same as the z -test for a normal mean discussed in Chapter 4 with s replaced by σ . Hence, the power function for this test is given in expression (4.6.5). ■

Other examples are given in the exercises. In these examples the likelihood ratio tests simplify and we are able to get the test in closed form. Often, though, this is impossible. In such cases, similarly to Example 6.2.7, we can obtain the mle by iterative routines and, hence, also the test statistic Λ . In Example 6.3.2, $-2 \log \Lambda$ had an exact $\chi^2(1)$ null distribution. While not true in general, as the following theorem shows, under regularity conditions, the asymptotic null distribution of $-2 \log \Lambda$ is χ^2 with one degree of freedom. Hence in all cases an asymptotic test can be constructed.

Theorem 6.3.1. *Assume the same regularity conditions as for Theorem 6.2.2. Under the null hypothesis, $H_0 : \theta = \theta_0$,*

$$-2 \log \Lambda \xrightarrow{D} \chi^2(1). \quad (6.3.7)$$

Proof: Expand the function $l(\theta)$ into a Taylor series about θ_0 of order 1 and evaluate it at the mle, $\hat{\theta}$. This results in

$$l(\hat{\theta}) = l(\theta_0) + (\hat{\theta} - \theta_0)l'(\theta_0) + \frac{1}{2}(\hat{\theta} - \theta_0)^2 l''(\theta_n^*), \quad (6.3.8)$$

where θ_n^* is between $\hat{\theta}$ and θ_0 . Because $\hat{\theta} \xrightarrow{P} \theta_0$, it follows that $\theta_n^* \xrightarrow{P} \theta_0$. This, in addition to the fact that the function $l''(\theta)$ is continuous, and equation (6.2.22) of Theorem 6.2.2 imply that

$$-\frac{1}{n}l''(\theta_n^*) \xrightarrow{P} I(\theta_0). \quad (6.3.9)$$

By Corollary 6.2.3,

$$\frac{1}{\sqrt{n}}l'(\theta_0) = \sqrt{n}(\hat{\theta} - \theta_0)I(\theta_0) + R_n, \quad (6.3.10)$$

where $R_n \rightarrow 0$, in probability. If we substitute (6.3.9) and (6.3.10) into expression (6.3.8) and do some simplification, we have

$$-2 \log \Lambda = 2(l(\hat{\theta}) - l(\theta_0)) = \{\sqrt{nI(\theta_0)}(\hat{\theta} - \theta_0)\}^2 + R_n^*, \quad (6.3.11)$$

where $R_n^* \rightarrow 0$, in probability. By Theorems 5.2.4 and 6.2.2, the first term on the right side of the above equation converges in distribution to a χ^2 -distribution with one degree of freedom. ■

Define the test statistic $\chi_L^2 = -2 \log \Lambda$. For the hypotheses (6.3.1), this theorem suggests the decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \chi_L^2 \geq \chi_\alpha^2(1). \quad (6.3.12)$$

By the last theorem, this test has asymptotic level α . If we cannot obtain the test statistic or its distribution in closed form, we can use this asymptotic test.

Besides the likelihood ratio test, in practice two other likelihood-related tests are employed. A natural test statistic is based on the asymptotic distribution of $\hat{\theta}$. Consider the statistic

$$\chi_W^2 = \left\{ \sqrt{nI(\hat{\theta})}(\hat{\theta} - \theta_0) \right\}^2. \quad (6.3.13)$$

Because $I(\theta)$ is a continuous function, $I(\hat{\theta}) \rightarrow I(\theta_0)$ in probability under the null hypothesis, (6.3.1). It follows, under H_0 , that χ_W^2 has an asymptotic χ^2 -distribution with one degree of freedom. This suggests the decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \chi_W^2 \geq \chi_\alpha^2(1). \quad (6.3.14)$$

As with the test based on χ_L^2 , this test has asymptotic level α . Actually, the relationship between the two test statistics is strong, because as equation (6.3.11) shows, under H_0 ,

$$\chi_W^2 - \chi_L^2 \xrightarrow{P} 0. \quad (6.3.15)$$

The test (6.3.14) is often referred to as a **Wald**-type test, after Abraham Wald, who was a prominent statistician of the 20th century.

The third test is called a **scores**-type test, which is often referred to as Rao's score test, after another prominent statistician, C. R. Rao. The **scores** are the components of the vector

$$\mathbf{S}(\theta) = \left(\frac{\partial \log f(X_1; \theta)}{\partial \theta}, \dots, \frac{\partial \log f(X_n; \theta)}{\partial \theta} \right)'. \quad (6.3.16)$$

In our notation, we have

$$\frac{1}{\sqrt{n}} l'(\theta_0) = \frac{1}{\sqrt{n}} \sum_{i=1}^n \frac{\partial \log f(X_i; \theta_0)}{\partial \theta}. \quad (6.3.17)$$

Define the statistic

$$\chi_R^2 = \left(\frac{l'(\theta_0)}{\sqrt{nI(\theta_0)}} \right)^2. \quad (6.3.18)$$

Under H_0 , it follows from expression (6.3.10) that

$$\chi_R^2 = \chi_W^2 + R_{0n}, \quad (6.3.19)$$

where R_{0n} converges to 0 in probability. Hence the following decision rule defines an asymptotic level α test under H_0 :

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \chi_R^2 \geq \chi_\alpha^2(1). \quad (6.3.20)$$

Example 6.3.3 (Example 6.2.6, Continued). As in Example 6.2.6, let X_1, \dots, X_n be a random sample having the common beta($\theta, 1$) pdf (6.2.14). We use this pdf to illustrate the three test statistics discussed above for the hypotheses

$$H_0 : \theta = 1 \text{ versus } H_1 : \theta \neq 1. \quad (6.3.21)$$

Under H_0 , $f(x; \theta)$ is the uniform(0, 1) pdf. Recall that $\hat{\theta} = -n / \sum_{i=1}^n \log X_i$ is the mle of θ . After some simplification, the value of the likelihood function at the mle is

$$L(\hat{\theta}) = \left(-\sum_{i=1}^n \log X_i \right)^{-n} \exp \left\{ -\sum_{i=1}^n \log X_i \right\} \exp \{ n(\log n - 1) \}.$$

Also, $L(1) = 1$. Hence the likelihood ratio test statistic is $\Lambda = 1/L(\hat{\theta})$, so that

$$\chi_L^2 = -2 \log \Lambda = 2 \left\{ -\sum_{i=1}^n \log X_i - n \log \left(-\sum_{i=1}^n \log X_i \right) - n + n \log n \right\}.$$

Recall that the information for this pdf is $I(\theta) = \theta^{-2}$. For the Wald-type test, we would estimate this consistently by $\hat{\theta}^{-2}$. The Wald-type test simplifies to

$$\chi_W^2 = \left(\sqrt{\frac{n}{\hat{\theta}^2}} (\hat{\theta} - 1) \right)^2 = n \left\{ 1 - \frac{1}{\hat{\theta}} \right\}^2. \quad (6.3.22)$$

Finally, for the scores-type course, recall from (6.2.15) that the $l'(1)$ is

$$l'(1) = \sum_{i=1}^n \log X_i + n.$$

Hence the scores-type test statistic is

$$\chi_R^2 = \left\{ \frac{\sum_{i=1}^n \log X_i + n}{\sqrt{n}} \right\}^2. \quad (6.3.23)$$

It is easy to show that expressions (6.3.22) and (6.3.23) are the same. From Example 6.2.4, we know the exact distribution of the maximum likelihood estimate. Exercise 6.3.8 uses this distribution to obtain an exact test. ■

Example 6.3.4 (Likelihood Tests for the Laplace Location Model). Consider the location model

$$X_i = \theta + e_i, \quad i = 1, \dots, n,$$

where $-\infty < \theta < \infty$ and the random errors e_i s are iid each having the Laplace pdf, (2.2.4). Technically, the Laplace distribution does not satisfy all of the regularity

conditions (R0)–(R5), but the results below can be derived rigorously; see, for example, Hettmansperger and McKean (2011). Consider testing the hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta \neq \theta_0,$$

where θ_0 is specified. Here $\Omega = (-\infty, \infty)$ and $\omega = \{\theta_0\}$. By Example 6.1.1, we know that the mle of θ under Ω is $Q_2 = \text{med}\{X_1, \dots, X_n\}$, the sample median. It follows that

$$L(\widehat{\Omega}) = 2^{-n} \exp \left\{ - \sum_{i=1}^n |x_i - Q_2| \right\},$$

while

$$L(\widehat{\omega}) = 2^{-n} \exp \left\{ - \sum_{i=1}^n |x_i - \theta_0| \right\}.$$

Hence the negative of twice the log of the likelihood ratio test statistic is

$$-2 \log \Lambda = 2 \left[\sum_{i=1}^n |x_i - \theta_0| - \sum_{i=1}^n |x_i - Q_2| \right]. \quad (6.3.24)$$

Thus the size α asymptotic likelihood ratio test for H_0 versus H_1 rejects H_0 in favor of H_1 if

$$2 \left[\sum_{i=1}^n |x_i - \theta_0| - \sum_{i=1}^n |x_i - Q_2| \right] \geq \chi_\alpha^2(1).$$

By (6.2.10), the Fisher information for this model is $I(\theta) = 1$. Thus, the Wald-type test statistic simplifies to

$$\chi_W^2 = [\sqrt{n}(Q_2 - \theta_0)]^2.$$

For the scores test, we have

$$\frac{\partial \log f(x_i - \theta)}{\partial \theta} = \frac{\partial}{\partial \theta} \left[\log \frac{1}{2} - |x_i - \theta| \right] = \text{sgn}(x_i - \theta).$$

Hence the score vector for this model is $\mathbf{S}(\theta) = (\text{sgn}(X_1 - \theta), \dots, \text{sgn}(X_n - \theta))'$. From the above discussion [see equation (6.3.17)], the scores test statistic can be written as

$$\chi_R^2 = (S^*)^2/n,$$

where

$$S^* = \sum_{i=1}^n \text{sgn}(X_i - \theta_0).$$

As Exercise 6.3.5 shows, under H_0 , S^* is a linear function of a random variable with a $b(n, 1/2)$ distribution. ■

Which of the three tests should we use? Based on the above discussion, all three tests are asymptotically equivalent under the null hypothesis. Similarly to the concept of asymptotic relative efficiency (ARE), we can derive an equivalent concept

of efficiency for tests; see Chapter 10 and more advanced books such as Hettmansperger and McKean (2011). However, all three tests have the same asymptotic efficiency. Hence, asymptotic theory offers little help in separating the tests. Finite sample comparisons have not shown that any of these tests are “best” overall; see Chapter 7 of Lehmann (1999) for more discussion.

EXERCISES

6.3.1. The following data were generated from an exponential distribution with pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, for $x > 0$, where $\theta = 40$.

- (a) Histogram the data and locate $\theta_0 = 50$ on the plot.
- (b) Use the test described in Example 6.3.1 to test $H_0 : \theta = 50$ versus $H_1 : \theta \neq 50$. Determine the decision at level $\alpha = 0.10$.

19 15 76 23 24 66 27 12 25 7 6 16 51 26 39

6.3.2. Consider the decision rule (6.3.5) derived in Example 6.3.1. Obtain the distribution of the test statistic under a general alternative and use it to obtain the power function of the test. Using R, sketch this power curve for the case when $\theta_0 = 1$, $n = 10$, and $\alpha = 0.05$.

6.3.3. Show that the test with decision rule (6.3.6) is like that of Example 4.6.1 except that here σ^2 is known.

6.3.4. Obtain an R function that plots the power function discussed at the end of Example 6.3.2. Run your function for the case when $\theta_0 = 0$, $n = 10$, $\sigma^2 = 1$, and $\alpha = 0.05$.

6.3.5. Consider Example 6.3.4.

- (a) Show that we can write $S^* = 2T - n$, where $T = \#\{X_i > \theta_0\}$.
- (b) Show that the scores test for this model is equivalent to rejecting H_0 if $T < c_1$ or $T > c_2$.
- (c) Show that under H_0 , T has the binomial distribution $b(n, 1/2)$; hence, determine c_1 and c_2 so that the test has size α .
- (d) Determine the power function for the test based on T as a function of θ .

6.3.6. Let X_1, X_2, \dots, X_n be a random sample from a $N(\mu_0, \sigma^2 = \theta)$ distribution, where $0 < \theta < \infty$ and μ_0 is known. Show that the likelihood ratio test of $H_0 : \theta = \theta_0$ versus $H_1 : \theta \neq \theta_0$ can be based upon the statistic $W = \sum_{i=1}^n (X_i - \mu_0)^2 / \theta_0$. Determine the null distribution of W and give, explicitly, the rejection rule for a level α test.

6.3.7. For the test described in Exercise 6.3.6, obtain the distribution of the test statistic under general alternatives. If computational facilities are available, sketch this power curve for the case when $\theta_0 = 1$, $n = 10$, $\mu = 0$, and $\alpha = 0.05$.

6.3.8. Using the results of Example 6.2.4, find an exact size α test for the hypotheses (6.3.21).

6.3.9. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with mean $\theta > 0$.

- (a) Show that the likelihood ratio test of $H_0 : \theta = \theta_0$ versus $H_1 : \theta \neq \theta_0$ is based upon the statistic $Y = \sum_{i=1}^n X_i$. Obtain the null distribution of Y .
- (b) For $\theta_0 = 2$ and $n = 5$, find the significance level of the test that rejects H_0 if $Y \leq 4$ or $Y \geq 17$.

6.3.10. Let X_1, X_2, \dots, X_n be a random sample from a Bernoulli $b(1, \theta)$ distribution, where $0 < \theta < 1$.

- (a) Show that the likelihood ratio test of $H_0 : \theta = \theta_0$ versus $H_1 : \theta \neq \theta_0$ is based upon the statistic $Y = \sum_{i=1}^n X_i$. Obtain the null distribution of Y .
- (b) For $n = 100$ and $\theta_0 = 1/2$, find c_1 so that the test rejects H_0 when $Y \leq c_1$ or $Y \geq c_2 = 100 - c_1$ has the approximate significance level of $\alpha = 0.05$. Hint: Use the Central Limit Theorem.

6.3.11. Let X_1, X_2, \dots, X_n be a random sample from a $\Gamma(\alpha = 4, \beta = \theta)$ distribution, where $0 < \theta < \infty$.

- (a) Show that the likelihood ratio test of $H_0 : \theta = \theta_0$ versus $H_1 : \theta \neq \theta_0$ is based upon the statistic $W = \sum_{i=1}^n X_i$. Obtain the null distribution of $2W/\theta_0$.
- (b) For $\theta_0 = 3$ and $n = 5$, find c_1 and c_2 so that the test that rejects H_0 when $W \leq c_1$ or $W \geq c_2$ has significance level 0.05.

6.3.12. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pdf $f(x; \theta) = \theta \exp\{-|x|^\theta\}/2\Gamma(1/\theta)$, $-\infty < x < \infty$, where $\theta > 0$. Suppose $\Omega = \{\theta : \theta = 1, 2\}$. Consider the hypotheses $H_0 : \theta = 2$ (a normal distribution) versus $H_1 : \theta = 1$ (a double exponential distribution). Show that the likelihood ratio test can be based on the statistic $W = \sum_{i=1}^n (X_i^2 - |X_i|)$.

6.3.13. Let X_1, X_2, \dots, X_n be a random sample from the beta distribution with $\alpha = \beta = \theta$ and $\Omega = \{\theta : \theta = 1, 2\}$. Show that the likelihood ratio test statistic Λ for testing $H_0 : \theta = 1$ versus $H_1 : \theta = 2$ is a function of the statistic $W = \sum_{i=1}^n \log X_i + \sum_{i=1}^n \log(1 - X_i)$.

6.3.14. Consider a location model

$$X_i = \theta + e_i, \quad i = 1, \dots, n, \quad (6.3.25)$$

where e_1, e_2, \dots, e_n are iid with pdf $f(z)$. There is a nice geometric interpretation for estimating θ . Let $\mathbf{X} = (X_1, \dots, X_n)'$ and $\mathbf{e} = (e_1, \dots, e_n)'$ be the vectors of observations and random error, respectively, and let $\boldsymbol{\mu} = \theta\mathbf{1}$, where $\mathbf{1}$ is a vector with all components equal to 1. Let V be the subspace of vectors of the form $\boldsymbol{\mu}$;

i.e., $V = \{\mathbf{v} : \mathbf{v} = a\mathbf{1}, \text{ for some } a \in R\}$. Then in vector notation we can write the model as

$$\mathbf{X} = \boldsymbol{\mu} + \mathbf{e}, \quad \boldsymbol{\mu} \in V. \quad (6.3.26)$$

Then we can summarize the model by saying, “Except for the random error vector \mathbf{e} , \mathbf{X} would reside in V .” Hence, it makes sense intuitively to estimate $\boldsymbol{\mu}$ by a vector in V that is “closest” to \mathbf{X} . That is, given a norm $\|\cdot\|$ in R^n , choose

$$\hat{\boldsymbol{\mu}} = \text{Argmin} \|\mathbf{X} - \mathbf{v}\|, \quad \mathbf{v} \in V. \quad (6.3.27)$$

- (a) If the error pdf is the Laplace, (2.2.4), show that the minimization in (6.3.27) is equivalent to maximizing the likelihood when the norm is the l_1 norm given by

$$\|\mathbf{v}\|_1 = \sum_{i=1}^n |v_i|. \quad (6.3.28)$$

- (b) If the error pdf is the $N(0, 1)$, show that the minimization in (6.3.27) is equivalent to maximizing the likelihood when the norm is given by the square of the l_2 norm

$$\|\mathbf{v}\|_2^2 = \sum_{i=1}^n v_i^2. \quad (6.3.29)$$

6.3.15. Continuing with Exercise 6.3.14, besides estimation there is also a nice geometric interpretation for testing. For the model (6.3.26), consider the hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta \neq \theta_0, \quad (6.3.30)$$

where θ_0 is specified. Given a norm $\|\cdot\|$ on R^n , denote by $d(\mathbf{X}, V)$ the distance between \mathbf{X} and the subspace V ; i.e., $d(\mathbf{X}, V) = \|\mathbf{X} - \hat{\boldsymbol{\mu}}\|$, where $\hat{\boldsymbol{\mu}}$ is defined in equation (6.3.27). If H_0 is true, then $\hat{\boldsymbol{\mu}}$ should be close to $\boldsymbol{\mu} = \theta_0\mathbf{1}$ and, hence, $\|\mathbf{X} - \theta_0\mathbf{1}\|$ should be close to $d(\mathbf{X}, V)$. Denote the difference by

$$RD = \|\mathbf{X} - \theta_0\mathbf{1}\| - \|\mathbf{X} - \hat{\boldsymbol{\mu}}\|. \quad (6.3.31)$$

Small values of RD indicate that the null hypothesis is true, while large values indicate H_1 . So our rejection rule when using RD is

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } RD > c. \quad (6.3.32)$$

- (a) If the error pdf is the Laplace, (6.1.6), show that expression (6.3.31) is equivalent to the likelihood ratio test when the norm is given by (6.3.28).
- (b) If the error pdf is the $N(0, 1)$, show that expression (6.3.31) is equivalent to the likelihood ratio test when the norm is given by the square of the l_2 norm, (6.3.29).

6.3.16. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pmf $p(x; \theta) = \theta^x(1-\theta)^{1-x}$, $x = 0, 1$, where $0 < \theta < 1$. We wish to test $H_0 : \theta = 1/3$ versus $H_1 : \theta \neq 1/3$.

- (a) Find Λ and $-2 \log \Lambda$.
- (b) Determine the Wald-type test.
- (c) What is Rao's score statistic?

6.3.17. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with mean $\theta > 0$. Consider testing $H_0 : \theta = \theta_0$ against $H_1 : \theta \neq \theta_0$.

- (a) Obtain the Wald type test of expression (6.3.13).
- (b) Write an R function to compute this test statistic.
- (c) For $\theta_0 = 23$, compute the test statistic and determine the p -value for the following data.

27 13 21 24 22 14 17 26 14 22
21 24 19 25 15 25 23 16 20 19

6.3.18. Let X_1, X_2, \dots, X_n be a random sample from a $\Gamma(\alpha, \beta)$ distribution where α is known and $\beta > 0$. Determine the likelihood ratio test for $H_0 : \beta = \beta_0$ against $H_1 : \beta \neq \beta_0$.

6.3.19. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from a uniform distribution on $(0, \theta)$, where $\theta > 0$.

- (a) Show that Λ for testing $H_0 : \theta = \theta_0$ against $H_1 : \theta \neq \theta_0$ is $\Lambda = (Y_n/\theta_0)^n$, $Y_n \leq \theta_0$, and $\Lambda = 0$ if $Y_n > \theta_0$.
- (b) When H_0 is true, show that $-2 \log \Lambda$ has an exact $\chi^2(2)$ distribution, not $\chi^2(1)$. Note that the regularity conditions are not satisfied.

6.4 Multiparameter Case: Estimation

In this section, we discuss the case where $\boldsymbol{\theta}$ is a vector of p parameters. There are analogs to the theorems in the previous sections in which θ is a scalar, and we present their results but, for the most part, without proofs. The interested reader can find additional information in more advanced books; see, for instance, Lehmann and Casella (1998) and Rao (1973).

Let X_1, \dots, X_n be iid with common pdf $f(x; \boldsymbol{\theta})$, where $\boldsymbol{\theta} \in \Omega \subset R^p$. As before, the likelihood function and its log are given by

$$\begin{aligned} L(\boldsymbol{\theta}) &= \prod_{i=1}^n f(x_i; \boldsymbol{\theta}) \\ l(\boldsymbol{\theta}) &= \log L(\boldsymbol{\theta}) = \sum_{i=1}^n \log f(x_i; \boldsymbol{\theta}), \end{aligned} \tag{6.4.1}$$

for $\boldsymbol{\theta} \in \Omega$. The theory requires additional regularity conditions, which are listed in Appendix A, (A.1.1). In keeping with our number scheme in the last three sections,

we have labeled these (R6)–(R9). In this section, when we say “under regularity conditions,” we mean all of the conditions of (6.1.1), (6.2.1), (6.2.2), and (A.1.1) that are relevant to the argument. The discrete case follows in the same way as the continuous case, so in general we state material in terms of the continuous case.

Note that the proof of Theorem 6.1.1 does not depend on whether the parameter is a scalar or a vector. Therefore, with probability going to 1, $L(\boldsymbol{\theta})$ is maximized at the true value of $\boldsymbol{\theta}$. Hence, as an estimate of $\boldsymbol{\theta}$ we consider the value that maximizes $L(\boldsymbol{\theta})$ or equivalently solves the vector equation $(\partial/\partial\boldsymbol{\theta})l(\boldsymbol{\theta}) = \mathbf{0}$. If it exists, this value is called the **maximum likelihood estimator** (mle) and we denote it by $\hat{\boldsymbol{\theta}}$. Often we are interested in a function of $\boldsymbol{\theta}$, say, the parameter $\eta = g(\boldsymbol{\theta})$. Because the second part of the proof of Theorem 6.1.2 remains true for $\boldsymbol{\theta}$ as a vector, $\hat{\eta} = g(\hat{\boldsymbol{\theta}})$ is the mle of η .

Example 6.4.1 (Maximum Likelihood Estimates Under the Normal Model). Suppose X_1, \dots, X_n are iid $N(\mu, \sigma^2)$. In this case, $\boldsymbol{\theta} = (\mu, \sigma^2)'$ and Ω is the product space $(-\infty, \infty) \times (0, \infty)$. The log of the likelihood simplifies to

$$l(\mu, \sigma^2) = -\frac{n}{2} \log 2\pi - n \log \sigma - \frac{1}{2\sigma^2} \sum_{i=1}^n (x_i - \mu)^2. \quad (6.4.2)$$

Taking partial derivatives of (6.4.2) with respect to μ and σ and setting them to 0, we get the simultaneous equations

$$\begin{aligned} \frac{\partial l}{\partial \mu} &= \frac{1}{\sigma^2} \sum_{i=1}^n (x_i - \mu) = 0 \\ \frac{\partial l}{\partial \sigma} &= -\frac{n}{\sigma} + \frac{1}{\sigma^3} \sum_{i=1}^n (x_i - \mu)^2 = 0. \end{aligned}$$

Solving these equations, we obtain $\hat{\mu} = \bar{X}$ and $\hat{\sigma} = \sqrt{(1/n) \sum_{i=1}^n (X_i - \bar{X})^2}$ as solutions. A check of the second partials shows that these maximize $l(\mu, \sigma^2)$, so these are the mles. Also, by Theorem 6.1.2, $(1/n) \sum_{i=1}^n (X_i - \bar{X})^2$ is the mle of σ^2 . We know from our discussion in Section 5.1 that these are consistent estimates of μ and σ^2 , respectively, that $\hat{\mu}$ is an unbiased estimate of μ , and that $\hat{\sigma}^2$ is a biased estimate of σ^2 whose bias vanishes as $n \rightarrow \infty$. ■

Example 6.4.2 (General Laplace pdf). Let X_1, X_2, \dots, X_n be a random sample from the Laplace pdf $f_X(x) = (2b)^{-1} \exp\{-|x - a|/b\}$, $-\infty < x < \infty$, where the parameters (a, b) are in the space $\Omega = \{(a, b) : -\infty < a < \infty, b > 0\}$. Recall in Section 6.1 that we looked at the special case where $b = 1$. As we now show, the mle of a is the sample median, regardless of the value of b . The log of the likelihood function is

$$l(a, b) = -n \log 2 - n \log b - \sum_{i=1}^n \left| \frac{x_i - a}{b} \right|.$$

The partial of $l(a, b)$ with respect to a is

$$\frac{\partial l(a, b)}{\partial a} = \frac{1}{b} \sum_{i=1}^n \operatorname{sgn} \left\{ \frac{x_i - a}{b} \right\} = \frac{1}{b} \sum_{i=1}^n \operatorname{sgn}\{x_i - a\},$$

where the second equality follows because $b > 0$. Setting this partial to 0, we obtain the mle of a to be $Q_2 = \text{med}\{X_1, X_2, \dots, X_n\}$, just as in Example 6.1.1. Hence the mle of a is invariant to the parameter b . Taking the partial of $l(a, b)$ with respect to b , we obtain

$$\frac{\partial l(a, b)}{\partial b} = -\frac{n}{b} + \frac{1}{b^2} \sum_{i=1}^n |x_i - a|.$$

Setting to 0 and solving the two equations simultaneously, we obtain, as the mle of b , the statistic

$$\hat{b} = \frac{1}{n} \sum_{i=1}^n |X_i - Q_2|. \quad \blacksquare$$

Recall that the Fisher information in the scalar case was the variance of the random variable $(\partial/\partial\theta) \log f(X; \theta)$. The analog in the multiparameter case is the variance-covariance matrix of the gradient of $\log f(X; \boldsymbol{\theta})$, that is, the variance-covariance matrix of the random vector given by

$$\nabla \log f(X; \boldsymbol{\theta}) = \left(\frac{\partial \log f(X; \boldsymbol{\theta})}{\partial \theta_1}, \dots, \frac{\partial \log f(X; \boldsymbol{\theta})}{\partial \theta_p} \right)'. \quad (6.4.3)$$

Fisher information is then defined by the $p \times p$ matrix

$$\mathbf{I}(\boldsymbol{\theta}) = \text{Cov}(\nabla \log f(X; \boldsymbol{\theta})). \quad (6.4.4)$$

The (j, k) th entry of $\mathbf{I}(\boldsymbol{\theta})$ is given by

$$I_{jk} = \text{cov} \left(\frac{\partial}{\partial \theta_j} \log f(X; \boldsymbol{\theta}), \frac{\partial}{\partial \theta_k} \log f(X; \boldsymbol{\theta}) \right); \quad j, k = 1, \dots, p. \quad (6.4.5)$$

As in the scalar case, we can simplify this by using the identity $1 = \int f(x; \boldsymbol{\theta}) dx$. Under the regularity conditions, as discussed in the second paragraph of this section, the partial derivative of this identity with respect to θ_j results in

$$\begin{aligned} 0 = \int \frac{\partial}{\partial \theta_j} f(x; \boldsymbol{\theta}) dx &= \int \left[\frac{\partial}{\partial \theta_j} \log f(x; \boldsymbol{\theta}) \right] f(x; \boldsymbol{\theta}) dx \\ &= E \left[\frac{\partial}{\partial \theta_j} \log f(X; \boldsymbol{\theta}) \right]. \end{aligned} \quad (6.4.6)$$

Next, on both sides of the first equality above, take the partial derivative with respect to θ_k . After simplification, this results in

$$\begin{aligned} 0 &= \int \left(\frac{\partial^2}{\partial \theta_j \partial \theta_k} \log f(x; \boldsymbol{\theta}) \right) f(x; \boldsymbol{\theta}) dx \\ &\quad + \int \left(\frac{\partial}{\partial \theta_j} \log f(x; \boldsymbol{\theta}) \frac{\partial}{\partial \theta_k} \log f(x; \boldsymbol{\theta}) \right) f(x; \boldsymbol{\theta}) dx; \end{aligned}$$

that is,

$$E \left[\frac{\partial}{\partial \theta_j} \log f(X; \boldsymbol{\theta}) \frac{\partial}{\partial \theta_k} \log f(X; \boldsymbol{\theta}) \right] = -E \left[\frac{\partial^2}{\partial \theta_j \partial \theta_k} \log f(X; \boldsymbol{\theta}) \right]. \quad (6.4.7)$$

Using (6.4.6) and (6.4.7) together, we obtain

$$I_{jk} = -E \left[\frac{\partial^2}{\partial \theta_j \partial \theta_k} \log f(X; \boldsymbol{\theta}) \right]. \quad (6.4.8)$$

Information for a random sample follows in the same way as the scalar case. The pdf of the sample is the likelihood function $L(\boldsymbol{\theta}; \mathbf{X})$. Replace $f(X; \boldsymbol{\theta})$ by $L(\boldsymbol{\theta}; \mathbf{X})$ in the vector given in expression (6.4.3). Because $\log L$ is a sum, this results in the random vector

$$\nabla \log L(\boldsymbol{\theta}; \mathbf{X}) = \sum_{i=1}^n \nabla \log f(X_i; \boldsymbol{\theta}). \quad (6.4.9)$$

Because the summands are iid with common covariance matrix $\mathbf{I}(\boldsymbol{\theta})$, we have

$$\text{Cov}(\nabla \log L(\boldsymbol{\theta}; \mathbf{X})) = n\mathbf{I}(\boldsymbol{\theta}). \quad (6.4.10)$$

As in the scalar case, the information in a random sample of size n is n times the information in a sample of size 1.

The diagonal entries of $\mathbf{I}(\boldsymbol{\theta})$ are

$$I_{ii}(\boldsymbol{\theta}) = \text{Var} \left[\frac{\partial \log f(X; \boldsymbol{\theta})}{\partial \theta_i} \right] = -E \left[\frac{\partial^2}{\partial \theta_i^2} \log f(X_i; \boldsymbol{\theta}) \right].$$

This is similar to the case when θ is a scalar, except now $I_{ii}(\boldsymbol{\theta})$ is a function of the vector $\boldsymbol{\theta}$. Recall in the scalar case that $(nI(\theta))^{-1}$ was the Rao-Cramér lower bound for an unbiased estimate of θ . There is an analog to this in the multiparameter case. In particular, if $Y_j = u_j(X_1, \dots, X_n)$ is an unbiased estimate of θ_j , then it can be shown that

$$\text{Var}(Y_j) \geq \frac{1}{n} [\mathbf{I}^{-1}(\boldsymbol{\theta})]_{jj}; \quad (6.4.11)$$

see, for example, Lehmann (1983). As in the scalar case, we shall call an unbiased estimate **efficient** if its variance attains this lower bound.

Example 6.4.3 (Information Matrix for the Normal pdf). The log of a $N(\mu, \sigma^2)$ pdf is given by

$$\log f(x; \mu, \sigma^2) = -\frac{1}{2} \log 2\pi - \log \sigma - \frac{1}{2\sigma^2} (x - \mu)^2. \quad (6.4.12)$$

The first and second partial derivatives are

$$\begin{aligned} \frac{\partial \log f}{\partial \mu} &= \frac{1}{\sigma^2} (x - \mu) \\ \frac{\partial^2 \log f}{\partial \mu^2} &= -\frac{1}{\sigma^2} \\ \frac{\partial \log f}{\partial \sigma} &= -\frac{1}{\sigma} + \frac{1}{\sigma^3} (x - \mu)^2 \\ \frac{\partial^2 \log f}{\partial \sigma^2} &= \frac{1}{\sigma^2} - \frac{3}{\sigma^4} (x - \mu)^2 \\ \frac{\partial^2 \log f}{\partial \mu \partial \sigma} &= -\frac{2}{\sigma^3} (x - \mu). \end{aligned}$$

Upon taking the negative of the expectations of the second partial derivatives, the information matrix for a normal density is

$$\mathbf{I}(\mu, \sigma) = \begin{bmatrix} \frac{1}{\sigma^2} & 0 \\ 0 & \frac{2}{\sigma^2} \end{bmatrix}. \quad (6.4.13)$$

We may want the information matrix for (μ, σ^2) . This can be obtained by taking partial derivatives with respect to σ^2 instead of σ ; however, in Example 6.4.6, we obtain it via a transformation. From Example 6.4.1, the maximum likelihood estimates of μ and σ^2 are $\hat{\mu} = \bar{X}$ and $\hat{\sigma}^2 = (1/n) \sum_{i=1}^n (X_i - \bar{X})^2$, respectively. Based on the information matrix, we note that \bar{X} is an efficient estimate of μ for finite samples. In Example 6.4.6, we consider the sample variance. ■

Example 6.4.4 (Information Matrix for a Location and Scale Family). Suppose X_1, X_2, \dots, X_n is a random sample with common pdf $f_X(x) = b^{-1} f\left(\frac{x-a}{b}\right)$, $-\infty < x < \infty$, where (a, b) is in the space $\Omega = \{(a, b) : -\infty < a < \infty, b > 0\}$ and $f(z)$ is a pdf such that $f(z) > 0$ for $-\infty < z < \infty$. As Exercise 6.4.10 shows, we can model X_i as

$$X_i = a + be_i, \quad (6.4.14)$$

where the e_i s are iid with pdf $f(z)$. This is called a *location and scale model* (LASP). Example 6.4.2 illustrated this model when $f(z)$ had the Laplace pdf. In Exercise 6.4.11, the reader is asked to show that the partial derivatives are

$$\begin{aligned} \frac{\partial}{\partial a} \left\{ \log \left[\frac{1}{b} f\left(\frac{x-a}{b}\right) \right] \right\} &= -\frac{1}{b} \frac{f'\left(\frac{x-a}{b}\right)}{f\left(\frac{x-a}{b}\right)} \\ \frac{\partial}{\partial b} \left\{ \log \left[\frac{1}{b} f\left(\frac{x-a}{b}\right) \right] \right\} &= -\frac{1}{b} \left[1 + \frac{\frac{x-a}{b} f'\left(\frac{x-a}{b}\right)}{f\left(\frac{x-a}{b}\right)} \right]. \end{aligned}$$

Using (6.4.5) and (6.4.6), we then obtain

$$I_{11} = \int_{-\infty}^{\infty} \frac{1}{b^2} \left[\frac{f'\left(\frac{x-a}{b}\right)}{f\left(\frac{x-a}{b}\right)} \right]^2 \frac{1}{b} f\left(\frac{x-a}{b}\right) dx.$$

Now make the substitution $z = (x-a)/b$, $dz = (1/b)dx$. Then we have

$$I_{11} = \frac{1}{b^2} \int_{-\infty}^{\infty} \left[\frac{f'(z)}{f(z)} \right]^2 f(z) dz; \quad (6.4.15)$$

hence, information on the location parameter a does not depend on a . As Exercise 6.4.11 shows, upon making this substitution, the other entries in the information matrix are

$$I_{22} = \frac{1}{b^2} \int_{-\infty}^{\infty} \left[1 + \frac{zf'(z)}{f(z)} \right]^2 f(z) dz \quad (6.4.16)$$

$$I_{12} = \frac{1}{b^2} \int_{-\infty}^{\infty} z \left[\frac{f'(z)}{f(z)} \right]^2 f(z) dz. \quad (6.4.17)$$

Thus, the information matrix can be written as $(1/b)^2$ times a matrix whose entries are free of the parameters a and b . As Exercise 6.4.12 shows, the off-diagonal entries of the information matrix are 0 if the pdf $f(z)$ is symmetric about 0. ■

Example 6.4.5 (Multinomial Distribution). Consider a random trial which can result in one, and only one, of k outcomes or categories. Let X_j be 1 or 0 depending on whether the j th outcome occurs or does not, for $j = 1, \dots, k$. Suppose the probability that outcome j occurs is p_j ; hence, $\sum_{j=1}^k p_j = 1$. Let $\mathbf{X} = (X_1, \dots, X_{k-1})'$ and $\mathbf{p} = (p_1, \dots, p_{k-1})'$. The distribution of \mathbf{X} is multinomial; see Section 3.1. Recall that the pmf is given by

$$f(\mathbf{x}, \mathbf{p}) = \left(\prod_{j=1}^{k-1} p_j^{x_j} \right) \left(1 - \sum_{j=1}^{k-1} p_j \right)^{1 - \sum_{j=1}^{k-1} x_j}, \quad (6.4.18)$$

where the parameter space is $\Omega = \{\mathbf{p} : 0 < p_j < 1, j = 1, \dots, k-1; \sum_{j=1}^{k-1} p_j < 1\}$.

We first obtain the information matrix. The first partial of the log of f with respect to p_i simplifies to

$$\frac{\partial \log f}{\partial p_i} = \frac{x_i}{p_i} - \frac{1 - \sum_{j=1}^{k-1} x_j}{1 - \sum_{j=1}^{k-1} p_j}.$$

The second partial derivatives are given by

$$\begin{aligned} \frac{\partial^2 \log f}{\partial p_i^2} &= -\frac{x_i}{p_i^2} - \frac{1 - \sum_{j=1}^{k-1} x_j}{(1 - \sum_{j=1}^{k-1} p_j)^2} \\ \frac{\partial^2 \log f}{\partial p_i \partial p_h} &= -\frac{1 - \sum_{j=1}^{k-1} x_j}{(1 - \sum_{j=1}^{k-1} p_j)^2}, \quad i \neq h < k. \end{aligned}$$

Recall that for this distribution the marginal distribution of X_j is Bernoulli with mean p_j . Recalling that $p_k = 1 - (p_1 + \dots + p_{k-1})$, the expectations of the negatives of the second partial derivatives are straightforward and result in the information matrix

$$\mathbf{I}(\mathbf{p}) = \begin{bmatrix} \frac{1}{p_1} + \frac{1}{p_k} & \frac{1}{p_k} & \cdots & \frac{1}{p_k} \\ \frac{1}{p_k} & \frac{1}{p_2} + \frac{1}{p_k} & \cdots & \frac{1}{p_k} \\ \vdots & \vdots & & \vdots \\ \frac{1}{p_k} & \frac{1}{p_k} & \cdots & \frac{1}{p_{k-1}} + \frac{1}{p_k} \end{bmatrix}. \quad (6.4.19)$$

This is a patterned matrix with inverse [see page 170 of Graybill (1969)],

$$\mathbf{I}^{-1}(\mathbf{p}) = \begin{bmatrix} p_1(1-p_1) & -p_1p_2 & \cdots & -p_1p_{k-1} \\ -p_1p_2 & p_2(1-p_2) & \cdots & -p_2p_{k-1} \\ \vdots & \vdots & & \vdots \\ -p_1p_{k-1} & -p_2p_{k-1} & \cdots & p_{k-1}(1-p_{k-1}) \end{bmatrix}. \quad (6.4.20)$$

Next, we obtain the mles for a random sample $\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_n$. The likelihood function is given by

$$L(\mathbf{p}) = \prod_{i=1}^n \prod_{j=1}^{k-1} p_j^{x_{ji}} \left(1 - \sum_{j=1}^{k-1} p_j\right)^{1-\sum_{j=1}^{k-1} x_{ji}}. \quad (6.4.21)$$

Let $t_j = \sum_{i=1}^n x_{ji}$, for $j = 1, \dots, k-1$. With simplification, the log of L reduces to

$$l(\mathbf{p}) = \sum_{j=1}^{k-1} t_j \log p_j + \left(n - \sum_{j=1}^{k-1} t_j\right) \log \left(1 - \sum_{j=1}^{k-1} p_j\right).$$

The first partial of $l(\mathbf{p})$ with respect to p_h leads to the system of equations

$$\frac{\partial l(\mathbf{p})}{\partial p_h} = \frac{t_h}{p_h} - \frac{n - \sum_{j=1}^{k-1} t_j}{1 - \sum_{j=1}^{k-1} p_j} = 0, \quad h = 1, \dots, k-1.$$

It is easily seen that $p_h = t_h/n$ satisfies these equations. Hence the maximum likelihood estimates are

$$\widehat{p}_h = \frac{\sum_{i=1}^n X_{ih}}{n}, \quad h = 1, \dots, k-1. \quad (6.4.22)$$

Each random variable $\sum_{i=1}^n X_{ih}$ is binomial(n, p_h) with variance $np_h(1-p_h)$. Therefore, the maximum likelihood estimates are efficient estimates. ■

As a final note on information, suppose the information matrix is diagonal. Then the lower bound of the variance of the j th estimator (6.4.11) is $1/(n\mathbf{I}_{jj}(\boldsymbol{\theta}))$. Because $\mathbf{I}_{jj}(\boldsymbol{\theta})$ is defined in terms of partial derivatives [see (6.4.5)] this is the information in treating all θ_i , except θ_j , as known. For instance, in Example 6.4.3, for the normal pdf the information matrix is diagonal; hence, the information for μ could have been obtained by treating σ^2 as known. Example 6.4.4 discusses the information for a general location and scale family. For this general family, of which the normal is a member, the information matrix is a diagonal matrix if the underlying pdf is symmetric.

In the next theorem, we summarize the asymptotic behavior of the maximum likelihood estimator of the vector $\boldsymbol{\theta}$. It shows that the mles are asymptotically efficient estimates.

Theorem 6.4.1. *Let X_1, \dots, X_n be iid with pdf $f(x; \boldsymbol{\theta})$ for $\boldsymbol{\theta} \in \Omega$. Assume the regularity conditions hold. Then*

1. *The likelihood equation,*

$$\frac{\partial}{\partial \boldsymbol{\theta}} l(\boldsymbol{\theta}) = \mathbf{0},$$

has a solution $\widehat{\boldsymbol{\theta}}_n$ such that $\widehat{\boldsymbol{\theta}}_n \xrightarrow{P} \boldsymbol{\theta}$.

2. For any sequence that satisfies (1),

$$\sqrt{n}(\hat{\boldsymbol{\theta}}_n - \boldsymbol{\theta}) \xrightarrow{D} N_p(\mathbf{0}, \mathbf{I}^{-1}(\boldsymbol{\theta})).$$

The proof of this theorem can be found in more advanced books; see, for example, Lehmann and Casella (1998). As in the scalar case, the theorem does not assure that the maximum likelihood estimates are unique. But if the sequence of solutions are unique, then they are both consistent and asymptotically normal. In applications, we can often verify uniqueness.

We immediately have the following corollary,

Corollary 6.4.1. Let X_1, \dots, X_n be iid with pdf $f(x; \boldsymbol{\theta})$ for $\boldsymbol{\theta} \in \Omega$. Assume the regularity conditions hold. Let $\hat{\boldsymbol{\theta}}_n$ be a sequence of consistent solutions of the likelihood equation. Then $\hat{\boldsymbol{\theta}}_n$ are asymptotically efficient estimates; that is, for $j = 1, \dots, p$,

$$\sqrt{n}(\hat{\boldsymbol{\theta}}_{n,j} - \theta_j) \xrightarrow{D} N(0, [\mathbf{I}^{-1}(\boldsymbol{\theta})]_{jj}).$$

Let \mathbf{g} be a transformation $\mathbf{g}(\boldsymbol{\theta}) = (g_1(\boldsymbol{\theta}), \dots, g_k(\boldsymbol{\theta}))'$ such that $1 \leq k \leq p$ and that the $k \times p$ matrix of partial derivatives

$$\mathbf{B} = \left[\frac{\partial g_i}{\partial \theta_j} \right], \quad i = 1, \dots, k, \quad j = 1, \dots, p,$$

has continuous elements and does not vanish in a neighborhood of $\boldsymbol{\theta}$. Let $\hat{\boldsymbol{\eta}} = \mathbf{g}(\hat{\boldsymbol{\theta}})$. Then $\hat{\boldsymbol{\eta}}$ is the mle of $\boldsymbol{\eta} = \mathbf{g}(\boldsymbol{\theta})$. By Theorem 5.4.6,

$$\sqrt{n}(\hat{\boldsymbol{\eta}} - \boldsymbol{\eta}) \xrightarrow{D} N_k(\mathbf{0}, \mathbf{B}\mathbf{I}^{-1}(\boldsymbol{\theta})\mathbf{B}'). \quad (6.4.23)$$

Hence the information matrix for $\sqrt{n}(\hat{\boldsymbol{\eta}} - \boldsymbol{\eta})$ is

$$\mathbf{I}(\boldsymbol{\eta}) = [\mathbf{B}\mathbf{I}^{-1}(\boldsymbol{\theta})\mathbf{B}']^{-1}, \quad (6.4.24)$$

provided that the inverse exists.

For a simple example of this result, reconsider Example 6.4.3.

Example 6.4.6 (Information for the Variance of a Normal Distribution). Suppose X_1, \dots, X_n are iid $N(\mu, \sigma^2)$. Recall from Example 6.4.3 that the information matrix was $\mathbf{I}(\mu, \sigma) = \text{diag}\{\sigma^{-2}, 2\sigma^{-2}\}$. Consider the transformation $g(\mu, \sigma) = \sigma^2$. Hence the matrix of partials \mathbf{B} is the row vector $[0 \ 2\sigma]$. Thus the information for σ^2 is

$$I(\sigma^2) = \left\{ [0 \ 2\sigma] \begin{bmatrix} \frac{1}{\sigma^2} & 0 \\ 0 & \frac{2}{\sigma^2} \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 2\sigma \end{bmatrix} \right\}^{-1} = \frac{1}{2\sigma^4}.$$

The Rao-Cramér lower bound for the variance of an estimator of σ^2 is $(2\sigma^4)/n$. Recall that the sample variance is unbiased for σ^2 , but its variance is $(2\sigma^4)/(n-1)$. Hence, it is not efficient for finite samples, but it is asymptotically efficient. ■

EXERCISES

6.4.1. A survey is taken of the citizens in a city as to whether or not they support the zoning plan that the city council is considering. The responses are: Yes, No, Indifferent, and Otherwise. Let p_1, p_2, p_3 , and p_4 denote the respective true probabilities of these responses. The results of the survey are:

Yes	No	Indifferent	Otherwise
60	45	70	25

- (a) Obtain the mles of p_i , $i = 1, \dots, 4$.
- (b) Obtain 95% confidence intervals, (4.2.7), for p_i , $i = 1, \dots, 4$.

6.4.2. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m be independent random samples from $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_4)$ distributions, respectively.

- (a) If $\Omega \subset R^3$ is defined by

$$\Omega = \{(\theta_1, \theta_2, \theta_3) : -\infty < \theta_i < \infty, i = 1, 2; 0 < \theta_3 = \theta_4 < \infty\},$$

find the mles of θ_1 , θ_2 , and θ_3 .

- (b) If $\Omega \subset R^2$ is defined by

$$\Omega = \{(\theta_1, \theta_3) : -\infty < \theta_1 = \theta_2 < \infty; 0 < \theta_3 = \theta_4 < \infty\},$$

find the mles of θ_1 and θ_3 .

6.4.3. Let X_1, X_2, \dots, X_n be iid, each with the distribution having pdf $f(x; \theta_1, \theta_2) = (1/\theta_2)e^{-(x-\theta_1)/\theta_2}$, $\theta_1 \leq x < \infty$, $-\infty < \theta_2 < \infty$, zero elsewhere. Find the maximum likelihood estimators of θ_1 and θ_2 .

6.4.4. The *Pareto distribution* is a frequently used model in the study of incomes and has the distribution function

$$F(x; \theta_1, \theta_2) = \begin{cases} 1 - (\theta_1/x)^{\theta_2} & \theta_1 \leq x \\ 0 & \text{elsewhere,} \end{cases}$$

where $\theta_1 > 0$ and $\theta_2 > 0$. If X_1, X_2, \dots, X_n is a random sample from this distribution, find the maximum likelihood estimators of θ_1 and θ_2 . (*Hint:* This exercise deals with a nonregular case.)

6.4.5. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from the uniform distribution of the continuous type over the closed interval $[\theta - \rho, \theta + \rho]$. Find the maximum likelihood estimators for θ and ρ . Are these two unbiased estimators?

6.4.6. Let X_1, X_2, \dots, X_n be a random sample from $N(\mu, \sigma^2)$.

- (a) If the constant b is defined by the equation $P(X \leq b) = 0.90$, find the mle of b .
- (b) If c is given constant, find the mle of $P(X \leq c)$.

6.4.7. The data file `normal50.rda` contains a random sample of size $n = 50$ for the situation described in Exercise 6.4.6. Download this data in R and obtain a histogram of the observations.

- (a) In Part (b) of Exercise 6.4.6, let $c = 58$ and let $\xi = P(X \leq c)$. Based on the data, compute the estimated value of the mle for ξ . Compare this estimate with the sample proportion, \hat{p} , of the data less than or equal to 58.
- (b) The R function `bootstrapcis64.R` computes a bootstrap confidence interval for the mle. Use this function to compute a 95% confidence interval for ξ . Compare your interval with that of expression (4.2.7) based on \hat{p} .

6.4.8. Consider Part (a) of Exercise 6.4.6.

- (a) Using the data of Exercise 6.4.7, compute the mle of b . Also obtain the estimate based on 90th percentile of the data.
- (b) Edit the R function `bootstrapcis64.R` to compute a bootstrap confidence interval for b . Then run your R function on the data of Exercise 6.4.7 to compute a 95% confidence interval for b .

6.4.9. Consider two Bernoulli distributions with unknown parameters p_1 and p_2 . If Y and Z equal the numbers of successes in two independent random samples, each of size n , from the respective distributions, determine the mles of p_1 and p_2 if we know that $0 \leq p_1 \leq p_2 \leq 1$.

6.4.10. Show that if X_i follows the model (6.4.14), then its pdf is $b^{-1}f((x-a)/b)$.

6.4.11. Verify the partial derivatives and the entries of the information matrix for the location and scale family as given in Example 6.4.4.

6.4.12. Suppose the pdf of X is of a location and scale family as defined in Example 6.4.4. Show that if $f(z) = f(-z)$, then the entry I_{12} of the information matrix is 0. Then argue that in this case the mles of a and b are asymptotically independent.

6.4.13. Suppose X_1, X_2, \dots, X_n are iid $N(\mu, \sigma^2)$. Show that X_i follows a location and scale family as given in Example 6.4.4. Obtain the entries of the information matrix as given in this example and show that they agree with the information matrix determined in Example 6.4.3.

6.5 Multiparameter Case: Testing

In the multiparameter case, hypotheses of interest often specify $\boldsymbol{\theta}$ to be in a sub-region of the space. For example, suppose X has a $N(\mu, \sigma^2)$ distribution. The full space is $\Omega = \{(\mu, \sigma^2) : \sigma^2 > 0, -\infty < \mu < \infty\}$. This is a two-dimensional space.

We may be interested though in testing that $\mu = \mu_0$, where μ_0 is a specified value. Here we are not concerned about the parameter σ^2 . Under H_0 , the parameter space is the one-dimensional space $\omega = \{(\mu_0, \sigma^2) : \sigma^2 > 0\}$. We say that H_0 is defined in terms of one constraint on the space Ω .

In general, let X_1, \dots, X_n be iid with pdf $f(x; \boldsymbol{\theta})$ for $\boldsymbol{\theta} \in \Omega \subset R^p$. As in the last section, we assume that the regularity conditions listed in (6.1.1), (6.2.1), (6.2.2), and (A.1.1) are satisfied. In this section, we invoke these by the phrase under regularity conditions. The hypotheses of interest are

$$H_0 : \boldsymbol{\theta} \in \omega \text{ versus } H_1 : \boldsymbol{\theta} \in \Omega \cap \omega^c, \quad (6.5.1)$$

where $\omega \subset \Omega$ is defined in terms of q , $0 < q \leq p$, independent constraints of the form $g_1(\boldsymbol{\theta}) = a_1, \dots, g_q(\boldsymbol{\theta}) = a_q$. The functions g_1, \dots, g_q must be continuously differentiable. This implies that ω is a $(p-q)$ -dimensional space. Based on Theorem 6.1.1, the true parameter maximizes the likelihood function, so an intuitive test statistic is given by the likelihood ratio

$$\Lambda = \frac{\max_{\boldsymbol{\theta} \in \omega} L(\boldsymbol{\theta})}{\max_{\boldsymbol{\theta} \in \Omega} L(\boldsymbol{\theta})}. \quad (6.5.2)$$

Large values (close to 1) of Λ suggest that H_0 is true, while small values indicate H_1 is true. For a specified level α , $0 < \alpha < 1$, this suggests the decision rule

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } \Lambda \leq c, \quad (6.5.3)$$

where c is such that $\alpha = \max_{\boldsymbol{\theta} \in \omega} P_{\boldsymbol{\theta}}[\Lambda \leq c]$. As in the scalar case, this test often has optimal properties; see Section 6.3. To determine c , we need to determine the distribution of Λ or a function of Λ when H_0 is true.

Let $\widehat{\boldsymbol{\theta}}$ denote the maximum likelihood estimator when the parameter space is the full space Ω and let $\widehat{\boldsymbol{\theta}}_0$ denote the maximum likelihood estimator when the parameter space is the reduced space ω . For convenience, define $L(\widehat{\Omega}) = L(\widehat{\boldsymbol{\theta}})$ and $L(\widehat{\omega}) = L(\widehat{\boldsymbol{\theta}}_0)$. Then we can write the **likelihood ratio test (LRT)** statistic as

$$\Lambda = \frac{L(\widehat{\omega})}{L(\widehat{\Omega})}. \quad (6.5.4)$$

Example 6.5.1 (LRT for the Mean of a Normal pdf). Let X_1, \dots, X_n be a random sample from a normal distribution with mean μ and variance σ^2 . Suppose we are interested in testing

$$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu \neq \mu_0, \quad (6.5.5)$$

where μ_0 is specified. Let $\Omega = \{(\mu, \sigma^2) : -\infty < \mu < \infty, \sigma^2 > 0\}$ denote the full model parameter space. The reduced model parameter space is the one-dimensional subspace $\omega = \{(\mu_0, \sigma^2) : \sigma^2 > 0\}$. By Example 6.4.1, the mles of μ and σ^2 under Ω are $\widehat{\mu} = \bar{X}$ and $\widehat{\sigma}^2 = (1/n) \sum_{i=1}^n (X_i - \bar{X})^2$, respectively. Under Ω , the maximum value of the likelihood function is

$$L(\widehat{\Omega}) = \frac{1}{(2\pi)^{n/2}} \frac{1}{(\widehat{\sigma}^2)^{n/2}} \exp\{-(n/2)\}. \quad (6.5.6)$$

Following Example 6.4.1, it is easy to show that under the reduced parameter space ω , $\widehat{\sigma}_0^2 = (1/n) \sum_{i=1}^n (X_i - \mu_0)^2$. Thus the maximum value of the likelihood function under ω is

$$L(\widehat{\omega}) = \frac{1}{(2\pi)^{n/2}} \frac{1}{(\widehat{\sigma}_0^2)^{n/2}} \exp\{-(n/2)\}. \quad (6.5.7)$$

The likelihood ratio test statistic is the ratio of $L(\widehat{\omega})$ to $L(\widehat{\Omega})$; i.e,

$$\Lambda = \left(\frac{\sum_{i=1}^n (X_i - \overline{X})^2}{\sum_{i=1}^n (X_i - \mu_0)^2} \right)^{n/2}. \quad (6.5.8)$$

The likelihood ratio test rejects H_0 if $\Lambda \leq c$, but this is equivalent to rejecting H_0 if $\Lambda^{-2/n} \geq c'$. Next, consider the identity

$$\sum_{i=1}^n (X_i - \mu_0)^2 = \sum_{i=1}^n (X_i - \overline{X})^2 + n(\overline{X} - \mu_0)^2. \quad (6.5.9)$$

Substituting (6.5.9) for $\sum_{i=1}^n (X_i - \mu_0)^2$, after simplification, the test becomes reject H_0 if

$$1 + \frac{n(\overline{X} - \mu_0)^2}{\sum_{i=1}^n (X_i - \overline{X})^2} \geq c',$$

or equivalently, reject H_0 if

$$\left\{ \frac{\sqrt{n}(\overline{X} - \mu_0)}{\sqrt{\sum_{i=1}^n (X_i - \overline{X})^2 / (n-1)}} \right\}^2 \geq c'' = (c' - 1)(n-1).$$

Let T denote the expression within braces on the left side of this inequality. Then the decision rule is equivalent to

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } |T| \geq c^*, \quad (6.5.10)$$

where $\alpha = P_{H_0}[|T| \geq c^*]$. Of course, this is the two-sided version of the t -test presented in Example 4.5.4. If we take c to be $t_{\alpha/2, n-1}$, the upper $\alpha/2$ -critical value of a t -distribution with $n-1$ degrees of freedom, then our test has exact level α . The power function for this test is discussed in Section 8.3.

As discussed in Example 4.2.1, the R call to compute t is `t.test(x, mu=mu0)`, where the vector `x` contains the sample and the scalar `mu0` is μ_0 . It also computes the t -confidence interval for μ . ■

Other examples of likelihood ratio tests for normal distributions can be found in the exercises.

We are not always as fortunate as in Example 6.5.1 to obtain the likelihood ratio test in a simple form. Often it is difficult or perhaps impossible to obtain its finite sample distribution. But, as the next theorem shows, we can always obtain an asymptotic test based on it.

Theorem 6.5.1. Let X_1, \dots, X_n be iid with pdf $f(x; \theta)$ for $\theta \in \Omega \subset R^p$. Assume the regularity conditions hold. Let $\hat{\theta}_n$ be a sequence of consistent solutions of the likelihood equation when the parameter space is the full space Ω . Let $\hat{\theta}_{0,n}$ be a sequence of consistent solutions of the likelihood equation when the parameter space is the reduced space ω , which has dimension $p - q$. Let Λ denote the likelihood ratio test statistic given in (6.5.4). Under H_0 , (6.5.1),

$$-2 \log \Lambda \xrightarrow{D} \chi^2(q). \quad (6.5.11)$$

A proof of this theorem can be found in Rao (1973).

There are analogs of the Wald-type and scores-type tests, also. The Wald-type test statistic is formulated in terms of the constraints, which define H_0 , evaluated at the mle under Ω . We do not formally state it here, but as the following example shows, it is often a straightforward formulation. The interested reader can find a discussion of these tests in Lehmann (1999).

A careful reading of the development of this chapter shows that much of it remains the same if X is a random vector. The next example demonstrates this.

Example 6.5.2 (Application of a Multinomial Distribution). As an example, consider a poll for a presidential race with k candidates. Those polled are asked to select the person for which they would vote if the election were held tomorrow. Assuming that those polled are selected independently of one another and that each can select one and only one candidate, the multinomial model seems appropriate. In this problem, suppose we are interested in comparing how the two “leaders” are doing. In fact, say the null hypothesis of interest is that they are equally favorable. This can be modeled with a multinomial model that has three categories: (1) and (2) for the two leading candidates and (3) for all other candidates. Our observation is a vector (X_1, X_2) , where X_i is 1 or 0 depending on whether category i is selected or not. If both are 0, then category (3) has been selected. Let p_i denote the probability that category i is selected. Then the pmf of (X_1, X_2) is the trinomial density,

$$f(x_1, x_2; p_1, p_2) = p_1^{x_1} p_2^{x_2} (1 - p_1 - p_2)^{1-x_1-x_2}, \quad (6.5.12)$$

for $x_i = 0, 1, i = 1, 2; x_1 + x_2 \leq 1$, where the parameter space is $\Omega = \{(p_1, p_2) : 0 < p_i < 1, p_1 + p_2 < 1\}$. Suppose $(X_{11}, X_{21}), \dots, (X_{1n}, X_{2n})$ is a random sample from this distribution. We shall consider the hypotheses

$$H_0 : p_1 = p_2 \text{ versus } H_1 : p_1 \neq p_2. \quad (6.5.13)$$

We first derive the likelihood ratio test. Let $T_j = \sum_{i=1}^n X_{ji}$ for $j = 1, 2$. From Example 6.4.5, we know that the maximum likelihood estimates are $\hat{p}_j = T_j/n$, for $j = 1, 2$. The value of the likelihood function (6.4.21) at the mles under Ω is

$$L(\hat{\Omega}) = \hat{p}_1^{n\hat{p}_1} \hat{p}_2^{n\hat{p}_2} (1 - \hat{p}_1 - \hat{p}_2)^{n(1-\hat{p}_1-\hat{p}_2)}.$$

Under the null hypothesis, let p be the common value of p_1 and p_2 . The pmf of (X_1, X_2) is

$$f(x_1, x_2; p) = p^{x_1+x_2} (1 - 2p)^{1-x_1-x_2}; \quad x_1, x_2 = 0, 1; x_1 + x_2 \leq 1, \quad (6.5.14)$$

where the parameter space is $\omega = \{p : 0 < p < 1/2\}$. The likelihood under ω is

$$L(p) = p^{t_1+t_2} (1-2p)^{n-t_1-t_2}. \quad (6.5.15)$$

Differentiating $\log L(p)$ with respect to p and setting the derivative to 0 results in the following maximum likelihood estimate, under ω :

$$\hat{p}_0 = \frac{t_1 + t_2}{2n} = \frac{\hat{p}_1 + \hat{p}_2}{2}, \quad (6.5.16)$$

where \hat{p}_1 and \hat{p}_2 are the mles under Ω . The likelihood function evaluated at the mle under ω simplifies to

$$L(\hat{\omega}) = \left(\frac{\hat{p}_1 + \hat{p}_2}{2} \right)^{n(\hat{p}_1 + \hat{p}_2)} (1 - \hat{p}_1 - \hat{p}_2)^{n(1 - \hat{p}_1 - \hat{p}_2)}. \quad (6.5.17)$$

The reciprocal of the likelihood ratio test statistic then simplifies to

$$\Lambda^{-1} = \left(\frac{2\hat{p}_1}{\hat{p}_1 + \hat{p}_2} \right)^{n\hat{p}_1} \left(\frac{2\hat{p}_2}{\hat{p}_1 + \hat{p}_2} \right)^{n\hat{p}_2}. \quad (6.5.18)$$

Based on Theorem 6.5.11, an asymptotic level α test rejects H_0 if $2 \log \Lambda^{-1} > \chi_{\alpha}^2(1)$.

This is an example where the Wald's test can easily be formulated. The constraint under H_0 is $p_1 - p_2 = 0$. Hence, the Wald-type statistic is $W = \hat{p}_1 - \hat{p}_2$, which can be expressed as $W = [1, -1][\hat{p}_1 ; \hat{p}_2]'$. Recall that the information matrix and its inverse were found for k categories in Example 6.4.5. From Theorem 6.4.1, we then have

$$\begin{bmatrix} \hat{p}_1 \\ \hat{p}_2 \end{bmatrix} \text{ is approximately } N_2 \left(\begin{pmatrix} p_1 \\ p_2 \end{pmatrix}, \frac{1}{n} \begin{bmatrix} p_1(1-p_1) & -p_1p_2 \\ -p_1p_2 & p_2(1-p_2) \end{bmatrix} \right). \quad (6.5.19)$$

As shown in Example 6.4.5, the finite sample moments are the same as the asymptotic moments. Hence the variance of W is

$$\begin{aligned} \text{Var}(W) &= [1, -1] \frac{1}{n} \begin{bmatrix} p_1(1-p_1) & -p_1p_2 \\ -p_1p_2 & p_2(1-p_2) \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix} \\ &= \frac{p_1 + p_2 - (p_1 - p_2)^2}{n}. \end{aligned}$$

Because W is asymptotically normal, an asymptotic level α test for the hypotheses (6.5.13) is to reject H_0 if $\chi_W^2 \geq \chi_{\alpha}^2(1)$, where

$$\chi_W^2 = \frac{(\hat{p}_1 - \hat{p}_2)^2}{(\hat{p}_1 + \hat{p}_2 - (\hat{p}_1 - \hat{p}_2)^2)/n}. \quad (6.5.20)$$

It also follows that an asymptotic $(1-\alpha)100\%$ confidence interval for the difference $p_1 - p_2$ is

$$\hat{p}_1 - \hat{p}_2 \pm z_{\alpha/2} \left(\frac{\hat{p}_1 + \hat{p}_2 - (\hat{p}_1 - \hat{p}_2)^2}{n} \right)^{1/2}. \quad (6.5.21)$$

Returning to the polling situation discussed at the beginning of this example, we would say the race is too close to call if 0 is in this confidence interval.

Equivalently, the test can be based on the test statistic $z = \sqrt{\chi^2_W}$, which has an asymptotic $N(0, 1)$ distribution under H_0 . This form of the test and the confidence interval for $p_1 - p_2$ are computed by the R function `p2pair.R`, which can be downloaded at the site mentioned in the Preface. ■

Example 6.5.3 (Two-Sample Binomial Proportions). In Example 6.5.2, we developed tests for $p_1 = p_2$ based on a single sample from a multinomial distribution. Now consider the situation where X_1, X_2, \dots, X_{n_1} is a random sample from a $b(1, p_1)$ distribution, Y_1, Y_2, \dots, Y_{n_2} is a random sample from a $b(1, p_2)$ distribution, and the X_i s and Y_j s are mutually independent. The hypotheses of interest are

$$H_0 : p_1 = p_2 \text{ versus } H_1 : p_1 \neq p_2. \quad (6.5.22)$$

This situation occurs in practice when, for instance, we are comparing the president's rating from one month to the next. The full and reduced model parameter spaces are given respectively by $\Omega = \{(p_1, p_2) : 0 < p_i < 1, i = 1, 2\}$ and $\omega = \{(p, p) : 0 < p < 1\}$. The likelihood function for the full model simplifies to

$$L(p_1, p_2) = p_1^{n_1 \bar{x}} (1 - p_1)^{n_1 - n_1 \bar{x}} p_2^{n_2 \bar{y}} (1 - p_2)^{n_2 - n_2 \bar{y}}. \quad (6.5.23)$$

It follows immediately that the mles of p_1 and p_2 are \bar{x} and \bar{y} , respectively. Note, for the reduced model, that we can combine the samples into one large sample from a $b(n, p)$ distribution, where $n = n_1 + n_2$ is the combined sample size. Hence, for the reduced model, the mle of p is

$$\hat{p} = \frac{\sum_{i=1}^{n_1} x_i + \sum_{i=1}^{n_2} y_i}{n_1 + n_2} = \frac{n_1 \bar{x} + n_2 \bar{y}}{n}, \quad (6.5.24)$$

i.e., a weighted average of the individual sample proportions. Using this, the reader is asked to derive the LRT for the hypotheses (6.5.22) in Exercise 6.5.12. We next derive the Wald-type test. Let $\hat{p}_1 = \bar{x}$ and $\hat{p}_2 = \bar{y}$. From the Central Limit Theorem, we have

$$\frac{\sqrt{n_i}(\hat{p}_i - p_i)}{\sqrt{p_i(1 - p_i)}} \xrightarrow{D} Z_i, \quad i = 1, 2,$$

where Z_1 and Z_2 are iid $N(0, 1)$ random variables. Assume for $i = 1, 2$ that, as $n \rightarrow \infty$, $n_i/n \rightarrow \lambda_i$, where $0 < \lambda_i < 1$ and $\lambda_1 + \lambda_2 = 1$. As Exercise 6.5.13 shows,

$$\sqrt{n}[(\hat{p}_1 - \hat{p}_2) - (p_1 - p_2)] \xrightarrow{D} N\left(0, \frac{1}{\lambda_1}p_1(1 - p_1) + \frac{1}{\lambda_2}p_2(1 - p_2)\right). \quad (6.5.25)$$

It follows that the random variable

$$Z = \frac{(\hat{p}_1 - \hat{p}_2) - (p_1 - p_2)}{\sqrt{\frac{p_1(1-p_1)}{n_1} + \frac{p_2(1-p_2)}{n_2}}} \quad (6.5.26)$$

has an approximate $N(0, 1)$ distribution. Under H_0 , $p_1 - p_2 = 0$. We could use Z as a test statistic, provided we replace the parameters $p_1(1 - p_1)$ and $p_2(1 - p_2)$

in its denominator with a consistent estimate. Recall that $\hat{p}_i \rightarrow p_i$, $i = 1, 2$, in probability. Thus under H_0 , the statistic

$$Z^* = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\frac{\hat{p}_1(1-\hat{p}_1)}{n_1} + \frac{\hat{p}_2(1-\hat{p}_2)}{n_2}}} \quad (6.5.27)$$

has an approximate $N(0, 1)$ distribution. Hence an approximate level α test is to reject H_0 if $|z^*| \geq z_{\alpha/2}$. Another consistent estimator of the denominator is discussed in Exercise 6.5.14. ■

EXERCISES

6.5.1. On page 80 of their test, Hollander and Wolfe (1999) present measurements of the ratio of the earth's mass to that of its moon that were made by 7 different spacecraft (5 of the Mariner type and 2 of the Pioneer type). These measurements are presented below (also in the file `earthmoon.rda`). Based on earlier Ranger voyages, scientists had set this ratio at 81.3035. Assuming a normal distribution, test the hypotheses $H_0 : \mu = 81.3035$ versus $H_1 : \mu \neq 81.3035$, where μ is the true mean ratio of these later voyages. Using the p -value, conclude in terms of the problem at the nominal α -level of 0.05.

Earth to Moon Mass Ratios						
81.3001	81.3015	81.3006	81.3011	81.2997	81.3005	81.3021

6.5.2. Obtain the boxplot of the data in Exercise 6.5.1. Mark the value 81.3035 on the plot. Compute the 95% confidence interval for μ , (4.2.3), and mark its endpoints on the plot. Comment.

6.5.3. Consider the survey of citizens discussed in Exercise 6.4.1. Suppose that the hypotheses of interest are $H_0 : p_1 = p_2$ versus $H_1 : p_1 \neq p_2$. Note that computation can be carried out using the R function `p2pair.R`, which can be downloaded at the site mentioned in the Preface.

- (a) Test these hypotheses at level $\alpha = 0.05$ using the test (6.5.20). Conclude in terms of the problem.
- (b) Obtain the 95% confidence interval, (6.5.21), for $p_1 - p_2$. What does the confidence interval mean in terms of the problem?

6.5.4. Let X_1, X_2, \dots, X_n be a random sample from the distribution $N(\theta_1, \theta_2)$. Show that the likelihood ratio principle for testing $H_0 : \theta_2 = \theta'_2$ specified, and θ_1 unspecified against $H_1 : \theta_2 \neq \theta'_2$, θ_1 unspecified, leads to a test that rejects when $\sum_1^n (x_i - \bar{x})^2 \leq c_1$ or $\sum_1^n (x_i - \bar{x})^2 \geq c_2$, where $c_1 < c_2$ are selected appropriately.

6.5.5. Let X_1, \dots, X_n and Y_1, \dots, Y_m be independent random samples from the distributions $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_4)$, respectively.

- (a) Show that the likelihood ratio for testing $H_0 : \theta_1 = \theta_2, \theta_3 = \theta_4$ against all alternatives is given by

$$\frac{\left[\sum_1^n (x_i - \bar{x})^2 / n \right]^{n/2} \left[\sum_1^m (y_i - \bar{y})^2 / m \right]^{m/2}}{\left\{ \left[\sum_1^n (x_i - u)^2 + \sum_1^m (y_i - u)^2 \right] / (m+n) \right\}^{(n+m)/2}},$$

where $u = (n\bar{x} + m\bar{y})/(n+m)$.

- (b) Show that the likelihood ratio test for testing $H_0 : \theta_3 = \theta_4, \theta_1$ and θ_2 unspecified, against $H_1 : \theta_3 \neq \theta_4, \theta_1$ and θ_2 unspecified, can be based on the random variable

$$F = \frac{\sum_1^n (X_i - \bar{X})^2 / (n-1)}{\sum_1^m (Y_i - \bar{Y})^2 / (m-1)}.$$

6.5.6. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m be independent random samples from the two normal distributions $N(0, \theta_1)$ and $N(0, \theta_2)$.

- (a) Find the likelihood ratio Λ for testing the composite hypothesis $H_0 : \theta_1 = \theta_2$ against the composite alternative $H_1 : \theta_1 \neq \theta_2$.
- (b) This Λ is a function of what F -statistic that would actually be used in this test?

6.5.7. Let X and Y be two independent random variables with respective pdfs

$$f(x; \theta_i) = \begin{cases} \left(\frac{1}{\theta_i}\right) e^{-x/\theta_i} & 0 < x < \infty, 0 < \theta_i < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

for $i = 1, 2$. To test $H_0 : \theta_1 = \theta_2$ against $H_1 : \theta_1 \neq \theta_2$, two independent samples of sizes n_1 and n_2 , respectively, were taken from these distributions. Find the likelihood ratio Λ and show that Λ can be written as a function of a statistic having an F -distribution, under H_0 .

6.5.8. For a numerical example of the F -test derived in Exercise 6.5.7, here are two generated data sets. The first was generated by the R call `rexp(10, 1/20)`, i.e., 10 observations from a $\Gamma(1, 20)$ -distribution. The second was generated by `rexp(12, 1/40)`. The data are rounded and can also be found in the file `genexpd.rda`.

- (a) Obtain comparison boxplots of the data sets. Comment.
- (b) Carry out the F -test of Exercise 6.5.7. Conclude in terms of the problem at level 0.05.

x: 11.1 11.7 12.7 9.6 14.7 1.6 1.7 56.1 3.3 2.6

y: 55.6 40.5 32.7 25.6 70.6 1.4 51.5 12.6 16.9 63.3 5.6 66.7

6.5.9. Consider the two uniform distributions with respective pdfs

$$f(x; \theta_i) = \begin{cases} \frac{1}{2\theta_i} & -\theta_i < x < \theta_i, -\infty < \theta_i < \infty \\ 0 & \text{elsewhere,} \end{cases}$$

for $i = 1, 2$. The null hypothesis is $H_0 : \theta_1 = \theta_2$, while the alternative is $H_1 : \theta_1 \neq \theta_2$. Let $X_1 < X_2 < \dots < X_{n_1}$ and $Y_1 < Y_2 < \dots < Y_{n_2}$ be the order statistics of two independent random samples from the respective distributions. Using the likelihood ratio Λ , find the statistic used to test H_0 against H_1 . Find the distribution of $-2 \log \Lambda$ when H_0 is true. Note that in this nonregular case, the number of degrees of freedom is two times the difference of the dimensions of Ω and ω .

6.5.10. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample from a bivariate normal distribution with $\mu_1, \mu_2, \sigma_1^2 = \sigma_2^2 = \sigma^2, \rho = \frac{1}{2}$, where μ_1, μ_2 , and $\sigma^2 > 0$ are unknown real numbers. Find the likelihood ratio Λ for testing $H_0 : \mu_1 = \mu_2 = 0, \sigma^2$ unknown against all alternatives. The likelihood ratio Λ is a function of what statistic that has a well-known distribution?

6.5.11. Let n independent trials of an experiment be such that x_1, x_2, \dots, x_k are the respective numbers of times that the experiment ends in the mutually exclusive and exhaustive events C_1, C_2, \dots, C_k . If $p_i = P(C_i)$ is constant throughout the n trials, then the probability of that particular sequence of trials is $L = p_1^{x_1} p_2^{x_2} \cdots p_k^{x_k}$.

- (a) Recalling that $p_1 + p_2 + \dots + p_k = 1$, show that the likelihood ratio for testing $H_0 : p_i = p_{i0} > 0, i = 1, 2, \dots, k$, against all alternatives is given by

$$\Lambda = \prod_{i=1}^k \left(\frac{(p_{i0})^{x_i}}{(x_i/n)^{x_i}} \right).$$

- (b) Show that

$$-2 \log \Lambda = \sum_{i=1}^k \frac{x_i(x_i - np_{i0})^2}{(np'_i)^2},$$

where p'_i is between p_{i0} and x_i/n .

Hint: Expand $\log p_{i0}$ in a Taylor's series with the remainder in the term involving $(p_{i0} - x_i/n)^2$.

- (c) For large n , argue that $x_i/(np'_i)^2$ is approximated by $1/(np_{i0})$ and hence

$$-2 \log \Lambda \approx \sum_{i=1}^k \frac{(x_i - np_{i0})^2}{np_{i0}} \quad \text{when } H_0 \text{ is true.}$$

Theorem 6.5.1 says that the right-hand member of this last equation defines a statistic that has an approximate chi-square distribution with $k - 1$ degrees of freedom. Note that

$$\text{dimension of } \Omega - \text{dimension of } \omega = (k - 1) - 0 = k - 1.$$

6.5.12. Finish the derivation of the LRT found in Example 6.5.3. Simplify as much as possible.

6.5.13. Show that expression (6.5.25) of Example 6.5.3 is true.

6.5.14. As discussed in Example 6.5.3, Z , (6.5.27), can be used as a test statistic provided that we have consistent estimators of $p_1(1 - p_1)$ and $p_2(1 - p_2)$ when H_0 is true. In the example, we discussed an estimator that is consistent under both H_0 and H_1 . Under H_0 , though, $p_1(1 - p_1) = p_2(1 - p_2) = p(1 - p)$, where $p = p_1 = p_2$. Show that the statistic (6.5.24) is a consistent estimator of p , under H_0 . Thus determine another test of H_0 .

6.5.15. A machine shop that manufactures toggle levers has both a day and a night shift. A toggle lever is defective if a standard nut cannot be screwed onto the threads. Let p_1 and p_2 be the proportion of defective levers among those manufactured by the day and night shifts, respectively. We shall test the null hypothesis, $H_0 : p_1 = p_2$, against a two-sided alternative hypothesis based on two random samples, each of 1000 levers taken from the production of the respective shifts. Use the test statistic Z^* given in Example 6.5.3.

- (a) Sketch a standard normal pdf illustrating the critical region having $\alpha = 0.05$.
- (b) If $y_1 = 37$ and $y_2 = 53$ defectives were observed for the day and night shifts, respectively, calculate the value of the test statistic and the approximate p -value (note that this is a two-sided test). Locate the calculated test statistic on your figure in part (a) and state your conclusion. Obtain the approximate p -value of the test.

6.5.16. For the situation given in part (b) of Exercise 6.5.15, calculate the tests defined in Exercises 6.5.12 and 6.5.14. Obtain the approximate p -values of all three tests. Discuss the results.

6.6 The EM Algorithm

In practice, we are often in the situation where part of the data is missing. For example, we may be observing lifetimes of mechanical parts that have been put on test and some of these parts are still functioning when the statistical analysis is carried out. In this section, we introduce the EM algorithm, which frequently can be used in these situations to obtain maximum likelihood estimates. Our presentation is brief. For further information, the interested reader can consult the literature in this area, including the monograph by McLachlan and Krishnan (1997). Although, for convenience, we write in terms of continuous random variables, the theory in this section holds for the discrete case as well.

Suppose we consider a sample of n items, where n_1 of the items are observed, while $n_2 = n - n_1$ items are not observable. Denote the observed items by $\mathbf{X}' = (X_1, X_2, \dots, X_{n_1})$ and unobserved items by $\mathbf{Z}' = (Z_1, Z_2, \dots, Z_{n_2})$. Assume that the X_i s are iid with pdf $f(x|\theta)$, where $\theta \in \Omega$. Assume that the Z_j s and the X_i s are

mutually independent. The conditional notation will prove useful here. Let $g(\mathbf{x}|\theta)$ denote the joint pdf of \mathbf{X} . Let $h(\mathbf{x}, \mathbf{z}|\theta)$ denote the joint pdf of the observed and unobserved items. Let $k(\mathbf{z}|\theta, \mathbf{x})$ denote the conditional pdf of the missing data given the observed data. By the definition of a conditional pdf, we have the identity

$$k(\mathbf{z}|\theta, \mathbf{x}) = \frac{h(\mathbf{x}, \mathbf{z}|\theta)}{g(\mathbf{x}|\theta)}. \quad (6.6.1)$$

The **observed likelihood** function is $L(\theta|\mathbf{x}) = g(\mathbf{x}|\theta)$. The **complete likelihood** function is defined by

$$L^c(\theta|\mathbf{x}, \mathbf{z}) = h(\mathbf{x}, \mathbf{z}|\theta). \quad (6.6.2)$$

Our goal is maximize the likelihood function $L(\theta|\mathbf{x})$ by using the complete likelihood $L^c(\theta|\mathbf{x}, \mathbf{z})$ in this process.

Using (6.6.1), we derive the following basic identity for an arbitrary but fixed $\theta_0 \in \Omega$:

$$\begin{aligned} \log L(\theta|\mathbf{x}) &= \int \log L(\theta|\mathbf{x}) k(\mathbf{z}|\theta_0, \mathbf{x}) d\mathbf{z} \\ &= \int \log g(\mathbf{x}|\theta) k(\mathbf{z}|\theta_0, \mathbf{x}) d\mathbf{z} \\ &= \int [\log h(\mathbf{x}, \mathbf{z}|\theta) - \log k(\mathbf{z}|\theta, \mathbf{x})] k(\mathbf{z}|\theta_0, \mathbf{x}) d\mathbf{z} \\ &= \int \log[h(\mathbf{x}, \mathbf{z}|\theta)] k(\mathbf{z}|\theta_0, \mathbf{x}) d\mathbf{z} - \int \log[k(\mathbf{z}|\theta, \mathbf{x})] k(\mathbf{z}|\theta_0, \mathbf{x}) d\mathbf{z} \\ &= E_{\theta_0}[\log L^c(\theta|\mathbf{x}, \mathbf{Z})|\theta_0, \mathbf{x}] - E_{\theta_0}[\log k(\mathbf{Z}|\theta, \mathbf{x})|\theta_0, \mathbf{x}], \end{aligned} \quad (6.6.3)$$

where the expectations are taken under the conditional pdf $k(\mathbf{z}|\theta_0, \mathbf{x})$. Define the first term on the right side of (6.6.3) to be the function

$$Q(\theta|\theta_0, \mathbf{x}) = E_{\theta_0}[\log L^c(\theta|\mathbf{x}, \mathbf{Z})|\theta_0, \mathbf{x}]. \quad (6.6.4)$$

The expectation that defines the function Q is called the *E* step of the EM algorithm. Recall that we want to maximize $\log L(\theta|\mathbf{x})$. As discussed below, we need only maximize $Q(\theta|\theta_0, \mathbf{x})$. This maximization is called the *M* step of the EM algorithm.

Denote by $\widehat{\theta}^{(0)}$ an initial estimate of θ , perhaps based on the observed likelihood. Let $\widehat{\theta}^{(1)}$ be the argument that maximizes $Q(\theta|\widehat{\theta}^{(0)}, \mathbf{x})$. This is the first-step estimate of θ . Proceeding this way, we obtain a sequence of estimates $\widehat{\theta}^{(m)}$. We formally define this algorithm as follows:

Algorithm 6.6.1 (EM Algorithm). *Let $\widehat{\theta}^{(m)}$ denote the estimate on the m th step. To compute the estimate on the $(m+1)$ st step, do*

1. *Expectation Step: Compute*

$$Q(\theta|\widehat{\theta}^{(m)}, \mathbf{x}) = E_{\widehat{\theta}^{(m)}}[\log L^c(\theta|\mathbf{x}, \mathbf{Z})|\widehat{\theta}_m, \mathbf{x}], \quad (6.6.5)$$

where the expectation is taken under the conditional pdf $k(\mathbf{z}|\widehat{\theta}^{(m)}, \mathbf{x})$.

2. Maximization Step: Let

$$\widehat{\theta}^{(m+1)} = \operatorname{Argmax} Q(\theta | \widehat{\theta}^{(m)}, \mathbf{x}). \quad (6.6.6)$$

Under strong assumptions, it can be shown that $\widehat{\theta}^{(m)}$ converges in probability to the maximum likelihood estimate, as $m \rightarrow \infty$. We will not show these results, but as the next theorem shows, $\widehat{\theta}^{(m+1)}$ always increases the likelihood over $\widehat{\theta}^{(m)}$.

Theorem 6.6.1. *The sequence of estimates $\widehat{\theta}^{(m)}$, defined by Algorithm 6.6.1, satisfies*

$$L(\widehat{\theta}^{(m+1)} | \mathbf{x}) \geq L(\widehat{\theta}^{(m)} | \mathbf{x}). \quad (6.6.7)$$

Proof: Because $\widehat{\theta}^{(m+1)}$ maximizes $Q(\theta | \widehat{\theta}^{(m)}, \mathbf{x})$, we have

$$Q(\widehat{\theta}^{(m+1)} | \widehat{\theta}^{(m)}, \mathbf{x}) \geq Q(\widehat{\theta}^{(m)} | \widehat{\theta}^{(m)}, \mathbf{x});$$

that is,

$$E_{\widehat{\theta}^{(m)}} [\log L^c(\widehat{\theta}^{(m+1)} | \mathbf{x}, \mathbf{Z})] \geq E_{\widehat{\theta}^{(m)}} [\log L^c(\widehat{\theta}^{(m)} | \mathbf{x}, \mathbf{Z})], \quad (6.6.8)$$

where the expectation is taken under the pdf $k(\mathbf{z} | \widehat{\theta}^{(m)}, \mathbf{x})$. By expression (6.6.3), we can complete the proof by showing that

$$E_{\widehat{\theta}^{(m)}} [\log k(\mathbf{Z} | \widehat{\theta}^{(m+1)}, \mathbf{x})] \leq E_{\widehat{\theta}^{(m)}} [\log k(\mathbf{Z} | \widehat{\theta}^{(m)}, \mathbf{x})]. \quad (6.6.9)$$

Keep in mind that these expectations are taken under the conditional pdf of \mathbf{Z} given $\widehat{\theta}^{(m)}$ and \mathbf{x} . An application of Jensen's inequality, (1.10.5), yields

$$\begin{aligned} E_{\widehat{\theta}^{(m)}} \left\{ \log \left[\frac{k(\mathbf{Z} | \widehat{\theta}^{(m+1)}, \mathbf{x})}{k(\mathbf{Z} | \widehat{\theta}^{(m)}, \mathbf{x})} \right] \right\} &\leq \log E_{\widehat{\theta}^{(m)}} \left[\frac{k(\mathbf{Z} | \widehat{\theta}^{(m+1)}, \mathbf{x})}{k(\mathbf{Z} | \widehat{\theta}^{(m)}, \mathbf{x})} \right] \\ &= \log \int \frac{k(\mathbf{z} | \widehat{\theta}^{(m+1)}, \mathbf{x})}{k(\mathbf{z} | \widehat{\theta}^{(m)}, \mathbf{x})} k(\mathbf{z} | \widehat{\theta}^{(m)}, \mathbf{x}) d\mathbf{z} \\ &= \log(1) = 0. \end{aligned} \quad (6.6.10)$$

This last result establishes (6.6.9) and, hence, finishes the proof. ■

As an example, suppose X_1, X_2, \dots, X_{n_1} are iid with pdf $f(x - \theta)$, for $-\infty < x < \infty$, where $-\infty < \theta < \infty$. Denote the cdf of X_i by $F(x - \theta)$. Let Z_1, Z_2, \dots, Z_{n_2} denote the censored observations. For these observations, we only know that $Z_j > a$, for some a that is known, and that the Z_j s are independent of the X_i s. Then the observed and complete likelihoods are given by

$$L(\theta | \mathbf{x}) = [1 - F(a - \theta)]^{n_2} \prod_{i=1}^{n_1} f(x_i - \theta) \quad (6.6.11)$$

$$L^c(\theta | \mathbf{x}, \mathbf{z}) = \prod_{i=1}^{n_1} f(x_i - \theta) \prod_{i=1}^{n_2} f(z_i - \theta). \quad (6.6.12)$$

By expression (6.6.1), the conditional distribution \mathbf{Z} given \mathbf{X} is the ratio of (6.6.12) to (6.6.11); that is,

$$\begin{aligned} k(\mathbf{z}|\theta, \mathbf{x}) &= \frac{\prod_{i=1}^{n_1} f(x_i - \theta) \prod_{i=1}^{n_2} f(z_i - \theta)}{[1 - F(a - \theta)]^{n_2} \prod_{i=1}^{n_1} f(x_i - \theta)} \\ &= [1 - F(a - \theta)]^{-n_2} \prod_{i=1}^{n_2} f(z_i - \theta), \quad a < z_i, i = 1, \dots, n_2. \end{aligned} \quad (6.6.13)$$

Thus, \mathbf{Z} and \mathbf{X} are independent, and Z_1, \dots, Z_{n_2} are iid with the common pdf $f(z - \theta)/[1 - F(a - \theta)]$, for $z > a$. Based on these observations and expression (6.6.13), we have the following derivation:

$$\begin{aligned} Q(\theta|\theta_0, \mathbf{x}) &= E_{\theta_0}[\log L^c(\theta|\mathbf{x}, \mathbf{Z})] \\ &= E_{\theta_0} \left[\sum_{i=1}^{n_1} \log f(x_i - \theta) + \sum_{i=1}^{n_2} \log f(Z_i - \theta) \right] \\ &= \sum_{i=1}^{n_1} \log f(x_i - \theta) + n_2 E_{\theta_0}[\log f(Z - \theta)] \\ &= \sum_{i=1}^{n_1} \log f(x_i - \theta) \\ &\quad + n_2 \int_a^\infty \log f(z - \theta) \frac{f(z - \theta_0)}{1 - F(a - \theta_0)} dz. \end{aligned} \quad (6.6.14)$$

This last result is the E step of the EM algorithm. For the M step, we need the partial derivative of $Q(\theta|\theta_0, \mathbf{x})$ with respect to θ . This is easily found to be

$$\frac{\partial Q}{\partial \theta} = - \left\{ \sum_{i=1}^{n_1} \frac{f'(x_i - \theta)}{f(x_i - \theta)} + n_2 \int_a^\infty \frac{f'(z - \theta)}{f(z - \theta)} \frac{f(z - \theta_0)}{1 - F(a - \theta_0)} dz \right\}. \quad (6.6.15)$$

Assuming that $\theta_0 = \hat{\theta}_0$, the first-step EM estimate would be the value of θ , say $\hat{\theta}^{(1)}$, which solves $\frac{\partial Q}{\partial \theta} = 0$. In the next example, we obtain the solution for a normal model.

Example 6.6.1. Assume the censoring model given above, but now assume that X has a $N(\theta, 1)$ distribution. Then $f(x) = \phi(x) = (2\pi)^{-1/2} \exp\{-x^2/2\}$. It is easy to show that $f'(x)/f(x) = -x$. Letting $\Phi(z)$ denote, as usual, the cdf of a standard normal random variable, by (6.6.15) the partial derivative of $Q(\theta|\theta_0, \mathbf{x})$ with respect to θ for this model simplifies to

$$\begin{aligned} \frac{\partial Q}{\partial \theta} &= \sum_{i=1}^{n_1} (x_i - \theta) + n_2 \int_a^\infty (z - \theta) \frac{1}{\sqrt{2\pi}} \frac{\exp\{-(z - \theta_0)^2/2\}}{1 - \Phi(a - \theta_0)} dz \\ &= n_1(\bar{x} - \theta) + n_2 \int_a^\infty (z - \theta_0) \frac{1}{\sqrt{2\pi}} \frac{\exp\{-(z - \theta_0)^2/2\}}{1 - \Phi(a - \theta_0)} dz - n_2(\theta - \theta_0) \\ &= n_1(\bar{x} - \theta) + \frac{n_2}{1 - \Phi(a - \theta_0)} \phi(a - \theta_0) - n_2(\theta - \theta_0). \end{aligned}$$

Solving $\partial Q/\partial\theta = 0$ for θ determines the EM step estimates. In particular, given that $\widehat{\theta}^{(m)}$ is the EM estimate on the m th step, the $(m+1)$ st step estimate is

$$\widehat{\theta}^{(m+1)} = \frac{n_1}{n}\bar{x} + \frac{n_2}{n}\widehat{\theta}^{(m)} + \frac{n_2}{n}\frac{\phi(a - \widehat{\theta}^{(m)})}{1 - \Phi(a - \widehat{\theta}^{(m)})}, \quad (6.6.16)$$

where $n = n_1 + n_2$. ■

For our second example, consider a mixture problem involving normal distributions. Suppose Y_1 has a $N(\mu_1, \sigma_1^2)$ distribution and Y_2 has a $N(\mu_2, \sigma_2^2)$ distribution. Let W be a Bernoulli random variable independent of Y_1 and Y_2 and with probability of success $\epsilon = P(W = 1)$. Suppose the random variable we observe is $X = (1 - W)Y_1 + WY_2$. In this case, the vector of parameters is given by $\boldsymbol{\theta}' = (\mu_1, \mu_2, \sigma_1, \sigma_2, \epsilon)$. As shown in Section 3.4, the pdf of the mixture random variable X is

$$f(x) = (1 - \epsilon)f_1(x) + \epsilon f_2(x), \quad -\infty < x < \infty, \quad (6.6.17)$$

where $f_j(x) = \sigma_j^{-1}\phi[(x - \mu_j)/\sigma_j]$, $j = 1, 2$, and $\phi(z)$ is the pdf of a standard normal random variable. Suppose we observe a random sample $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ from this mixture distribution with pdf $f(x)$. Then the log of the likelihood function is

$$l(\boldsymbol{\theta}|\mathbf{x}) = \sum_{i=1}^n \log[(1 - \epsilon)f_1(x_i) + \epsilon f_2(x_i)]. \quad (6.6.18)$$

In this mixture problem, the unobserved data are the random variables that identify the distribution membership. For $i = 1, 2, \dots, n$, define the random variables

$$W_i = \begin{cases} 0 & \text{if } X_i \text{ has pdf } f_1(x) \\ 1 & \text{if } X_i \text{ has pdf } f_2(x). \end{cases}$$

These variables, of course, constitute the random sample on the Bernoulli random variable W . Accordingly, assume that W_1, W_2, \dots, W_n are iid Bernoulli random variables with probability of success ϵ . The complete likelihood function is

$$L^c(\boldsymbol{\theta}|\mathbf{x}, \mathbf{w}) = \prod_{W_i=0} f_1(x_i) \prod_{W_i=1} f_2(x_i).$$

Hence the log of the complete likelihood function is

$$\begin{aligned} l^c(\boldsymbol{\theta}|\mathbf{x}, \mathbf{w}) &= \sum_{W_i=0} \log f_1(x_i) + \sum_{W_i=1} \log f_2(x_i) \\ &= \sum_{i=1}^n [(1 - w_i) \log f_1(x_i) + w_i \log f_2(x_i)]. \end{aligned} \quad (6.6.19)$$

For the E step of the algorithm, we need the conditional expectation of W_i given \mathbf{x} under $\boldsymbol{\theta}_0$; that is,

$$E_{\boldsymbol{\theta}_0}[W_i|\boldsymbol{\theta}_0, \mathbf{x}] = P[W_i = 1|\boldsymbol{\theta}_0, \mathbf{x}].$$

An estimate of this expectation is the likelihood of x_i being drawn from distribution $f_2(x)$, which is given by

$$\gamma_i = \frac{\hat{e}f_{2,0}(x_i)}{(1 - \hat{e})f_{1,0}(x_i) + \hat{e}f_{2,0}(x_i)}, \quad (6.6.20)$$

where the subscript 0 signifies that the parameters at θ_0 are being used. Expression (6.6.20) is intuitively evident; see McLachlan and Krishnan (1997) for more discussion. Replacing w_i by γ_i in expression (6.6.19), the M step of the algorithm is to maximize

$$Q(\theta|\theta_0, \mathbf{x}) = \sum_{i=1}^n [(1 - \gamma_i) \log f_1(x_i) + \gamma_i \log f_2(x_i)]. \quad (6.6.21)$$

This maximization is easy to obtain by taking partial derivatives of $Q(\theta|\theta_0, \mathbf{x})$ with respect to the parameters. For example,

$$\frac{\partial Q}{\partial \mu_1} = \sum_{i=1}^n (1 - \gamma_i)(-1/2\sigma_1^2)(-2)(x_i - \mu_1).$$

Setting this to 0 and solving for μ_1 yields the estimate of μ_1 . The estimates of the other mean and the variances can be obtained similarly. These estimates are

$$\begin{aligned}\hat{\mu}_1 &= \frac{\sum_{i=1}^n (1 - \gamma_i)x_i}{\sum_{i=1}^n (1 - \gamma_i)} \\ \hat{\sigma}_1^2 &= \frac{\sum_{i=1}^n (1 - \gamma_i)(x_i - \hat{\mu}_1)^2}{\sum_{i=1}^n (1 - \gamma_i)} \\ \hat{\mu}_2 &= \frac{\sum_{i=1}^n \gamma_i x_i}{\sum_{i=1}^n \gamma_i} \\ \hat{\sigma}_2^2 &= \frac{\sum_{i=1}^n \gamma_i (x_i - \hat{\mu}_2)^2}{\sum_{i=1}^n \gamma_i}.\end{aligned}$$

Since γ_i is an estimate of $P[W_i = 1|\theta_0, \mathbf{x}]$, the average $n^{-1} \sum_{i=1}^n \gamma_i$ is an estimate of $e = P[W_i = 1]$. This average is our estimate of \hat{e} .

EXERCISES

6.6.1. Rao (page 368, 1973) considers a problem in the estimation of linkages in genetics. McLachlan and Krishnan (1997) also discuss this problem and we present their model. For our purposes, it can be described as a multinomial model with the four categories C_1, C_2, C_3 , and C_4 . For a sample of size n , let $\mathbf{X} = (X_1, X_2, X_3, X_4)'$ denote the observed frequencies of the four categories. Hence, $n = \sum_{i=1}^4 X_i$. The probability model is

C_1	C_2	C_3	C_4
$\frac{1}{2} + \frac{1}{4}\theta$	$\frac{1}{4} - \frac{1}{4}\theta$	$\frac{1}{4} - \frac{1}{4}\theta$	$\frac{1}{4}\theta$

where the parameter θ satisfies $0 \leq \theta \leq 1$. In this exercise, we obtain the mle of θ .

- (a) Show that likelihood function is given by

$$L(\theta|\mathbf{x}) = \frac{n!}{x_1!x_2!x_3!x_4!} \left[\frac{1}{2} + \frac{1}{4}\theta \right]^{x_1} \left[\frac{1}{4} - \frac{1}{4}\theta \right]^{x_2+x_3} \left[\frac{1}{4}\theta \right]^{x_4}. \quad (6.6.22)$$

- (b) Show that the log of the likelihood function can be expressed as a constant (not involving parameters) plus the term

$$x_1 \log[2 + \theta] + [x_2 + x_3] \log[1 - \theta] + x_4 \log \theta.$$

- (c) Obtain the partial derivative with respect to θ of the last expression, set the result to 0, and solve for the mle. (This will result in a quadratic equation that has one positive and one negative root.)

6.6.2. In this exercise, we set up an EM algorithm to determine the mle for the situation described in Exercise 6.6.1. Split category C_1 into the two subcategories C_{11} and C_{12} with probabilities $1/2$ and $\theta/4$, respectively. Let Z_{11} and Z_{12} denote the respective “frequencies.” Then $X_1 = Z_{11} + Z_{12}$. Of course, we cannot observe Z_{11} and Z_{12} . Let $\mathbf{Z} = (Z_{11}, Z_{12})'$.

- (a) Obtain the complete likelihood $L^c(\theta|\mathbf{x}, \mathbf{z})$.
- (b) Using the last result and (6.6.22), show that the conditional pmf $k(\mathbf{z}|\theta, \mathbf{x})$ is binomial with parameters x_1 and probability of success $\theta/(2 + \theta)$.
- (c) Obtain the E step of the EM algorithm given an initial estimate $\hat{\theta}^{(0)}$ of θ . That is, obtain

$$Q(\theta|\hat{\theta}^{(0)}, \mathbf{x}) = E_{\hat{\theta}^{(0)}} [\log L^c(\theta|\mathbf{x}, \mathbf{Z})|\hat{\theta}^{(0)}, \mathbf{x}].$$

Recall that this expectation is taken using the conditional pmf $k(\mathbf{z}|\hat{\theta}^{(0)}, \mathbf{x})$. Keep in mind the next step; i.e., we need only terms that involve θ .

- (d) For the M step of the EM algorithm, solve the equation $\partial Q(\theta|\hat{\theta}^{(0)}, \mathbf{x})/\partial\theta = 0$. Show that the solution is

$$\hat{\theta}^{(1)} = \frac{x_1\hat{\theta}^{(0)} + 2x_4 + x_4\hat{\theta}^{(0)}}{n\hat{\theta}^{(0)} + 2(x_2 + x_3 + x_4)}. \quad (6.6.23)$$

6.6.3. For the setup of Exercise 6.6.2, show that the following estimator of θ is unbiased:

$$\tilde{\theta} = n^{-1}(X_1 - X_2 - X_3 + X_4). \quad (6.6.24)$$

6.6.4. Rao (page 368, 1973) presents data for the situation described in Exercise 6.6.1. The observed frequencies are $\mathbf{x} = (125, 18, 20, 34)'$.

- (a) Using computational packages (for example, R), with (6.6.24) as the initial estimate, write a program that obtains the stepwise EM estimates $\hat{\theta}^{(k)}$.

- (b) Using the data from Rao, compute the EM estimate of θ with your program. List the sequence of EM estimates, $\{\hat{\theta}^k\}$, that you obtained. Did your sequence of estimates converge?
- (c) Show that the mle using the likelihood approach in Exercise 6.6.1 is the positive root of the equation $197\theta^2 - 15\theta - 68 = 0$. Compare it with your EM solution. They should be the same within roundoff error.

6.6.5. Suppose X_1, X_2, \dots, X_{n_1} is a random sample from a $N(\theta, 1)$ distribution. Besides these n_1 observable items, suppose there are n_2 missing items, which we denote by Z_1, Z_2, \dots, Z_{n_2} . Show that the first-step EM estimate is

$$\hat{\theta}^{(1)} = \frac{n_1 \bar{x} + n_2 \hat{\theta}^{(0)}}{n},$$

where $\hat{\theta}^{(0)}$ is an initial estimate of θ and $n = n_1 + n_2$. Note that if $\hat{\theta}^{(0)} = \bar{x}$, then $\hat{\theta}^{(k)} = \bar{x}$ for all k .

6.6.6. Consider the situation described in Example 6.6.1. But suppose we have left censoring. That is, if Z_1, Z_2, \dots, Z_{n_2} are the censored items, then all we know is that each $Z_j < a$. Obtain the EM algorithm estimate of θ .

6.6.7. Suppose these data follow the model of Example 6.6.1:

$$\begin{array}{cccccccc} 2.01 & 0.74 & 0.68 & 1.50^+ & 1.47 & 1.50^+ & 1.50^+ & 1.52 \\ 0.07 & -0.04 & -0.21 & 0.05 & -0.09 & 0.67 & 0.14 \end{array}$$

where the superscript $+$ denotes that the observation was censored at 1.50. Write a computer program to obtain the EM algorithm estimate of θ .

6.6.8. The following data are observations of the random variable $X = (1 - W)Y_1 + WY_2$, where W has a Bernoulli distribution with probability of success 0.70; Y_1 has a $N(100, 20^2)$ distribution; Y_2 has a $N(120, 25^2)$ distribution; W and Y_1 are independent; and W and Y_2 are independent. Data are in the file `mix668.rda`.

$$\begin{array}{cccccccc} 119.0 & 96.0 & 146.2 & 138.6 & 143.4 & 98.2 & 124.5 \\ 114.1 & 136.2 & 136.4 & 184.8 & 79.8 & 151.9 & 114.2 \\ 145.7 & 95.9 & 97.3 & 136.4 & 109.2 & 103.2 \end{array}$$

Program the EM algorithm for this mixing problem as discussed at the end of the section. Use a dotplot to obtain initial estimates of the parameters. Compute the estimates. How close are they to the true parameters? Note: assuming the R vector `x` contains the sample on X , a quick dotplot in R is computed by `plot(rep(1, 20) ~ x)`.

Chapter 7

Sufficiency

7.1 Measures of Quality of Estimators

In Chapters 4 and 6 we presented procedures for finding point estimates, interval estimates, and tests of statistical hypotheses based on likelihood theory. In this and the next chapter, we present some optimal point estimates and tests for certain situations. We first consider point estimation.

In this chapter, as in Chapters 4 and 6, we find it convenient to use the letter f to denote a pmf as well as a pdf. It is clear from the context whether we are discussing the distributions of discrete or continuous random variables.

Suppose $f(x; \theta)$ for $\theta \in \Omega$ is the pdf (pmf) of a continuous (discrete) random variable X . Consider a point estimator $Y_n = u(X_1, \dots, X_n)$ based on a sample X_1, \dots, X_n . In Chapters 4 and 5, we discussed several properties of point estimators. Recall that Y_n is a consistent estimator (Definition 5.1.2) of θ if Y_n converges to θ in probability; i.e., Y_n is close to θ for large sample sizes. This is definitely a desirable property of a point estimator. Under suitable conditions, Theorem 6.1.3 shows that the maximum likelihood estimator is consistent. Another property was unbiasedness (Definition 4.1.3), which says that Y_n is an unbiased estimator of θ if $E(Y_n) = \theta$. Recall that maximum likelihood estimators may not be unbiased, although generally they are asymptotically unbiased (see Theorem 6.2.2).

If two estimators of θ are unbiased, it would seem that we would choose the one with the smaller variance. This would be especially true if they were both approximately normal because the one with the smaller asymptotic variance (and hence asymptotic standard error) would tend to produce shorter asymptotic confidence intervals for θ . This leads to the following definition:

Definition 7.1.1. *For a given positive integer n , $Y = u(X_1, X_2, \dots, X_n)$ is called a **minimum variance unbiased estimator (MVUE)** of the parameter θ if Y is unbiased, that is, $E(Y) = \theta$, and if the variance of Y is less than or equal to the variance of every other unbiased estimator of θ .*

Example 7.1.1. As an illustration, let X_1, X_2, \dots, X_9 denote a random sample from a distribution that is $N(\theta, \sigma^2)$, where $-\infty < \theta < \infty$. Because the statistic

$\bar{X} = (X_1 + X_2 + \dots + X_9)/9$ is $N(\theta, \frac{\sigma^2}{9})$, \bar{X} is an unbiased estimator of θ . The statistic X_1 is $N(\theta, \sigma^2)$, so X_1 is also an unbiased estimator of θ . Although the variance $\frac{\sigma^2}{9}$ of \bar{X} is less than the variance σ^2 of X_1 , we cannot say, with $n = 9$, that \bar{X} is the minimum variance unbiased estimator (MVUE) of θ ; that definition requires that the comparison be made with every unbiased estimator of θ . To be sure, it is quite impossible to tabulate all other unbiased estimators of this parameter θ , so other methods must be developed for making the comparisons of the variances. A beginning on this problem is made in this chapter. ■

Let us now discuss the problem of point estimation of a parameter from a slightly different standpoint. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution that has the pdf $f(x; \theta)$, $\theta \in \Omega$. The distribution may be of either the continuous or the discrete type. Let $Y = u(X_1, X_2, \dots, X_n)$ be a statistic on which we wish to base a point estimate of the parameter θ . Let $\delta(y)$ be that function of the observed value of the statistic Y which is the point estimate of θ . Thus the function δ decides the value of our point estimate of θ and δ is called a **decision function** or a **decision rule**. One value of the decision function, say $\delta(y)$, is called a *decision*. Thus a numerically determined point estimate of a parameter θ is a decision. Now a decision may be correct or it may be wrong. It would be useful to have a measure of the seriousness of the difference, if any, between the true value of θ and the point estimate $\delta(y)$. Accordingly, with each pair, $[\theta, \delta(y)]$, $\theta \in \Omega$, we associate a nonnegative number $\mathcal{L}[\theta, \delta(y)]$ that reflects this seriousness. We call the function \mathcal{L} the **loss function**. The expected (mean) value of the loss function is called the **risk function**. If $f_Y(y; \theta)$, $\theta \in \Omega$, is the pdf of Y , the risk function $R(\theta, \delta)$ is given by

$$R(\theta, \delta) = E\{\mathcal{L}[\theta, \delta(y)]\} = \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(y)] f_Y(y; \theta) dy$$

if Y is a random variable of the continuous type. It would be desirable to select a decision function that minimizes the risk $R(\theta, \delta)$ for all values of θ , $\theta \in \Omega$. But this is usually impossible because the decision function δ that minimizes $R(\theta, \delta)$ for one value of θ may not minimize $R(\theta, \delta)$ for another value of θ . Accordingly, we need either to restrict our decision function to a certain class or to consider methods of ordering the risk functions. The following example, while very simple, dramatizes these difficulties.

Example 7.1.2. Let X_1, X_2, \dots, X_{25} be a random sample from a distribution that is $N(\theta, 1)$, for $-\infty < \theta < \infty$. Let $Y = \bar{X}$, the mean of the random sample, and let $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. We shall compare the two decision functions given by $\delta_1(y) = y$ and $\delta_2(y) = 0$ for $-\infty < y < \infty$. The corresponding risk functions are

$$R(\theta, \delta_1) = E[(\theta - Y)^2] = \frac{1}{25}$$

and

$$R(\theta, \delta_2) = E[(\theta - 0)^2] = \theta^2.$$

If, in fact, $\theta = 0$, then $\delta_2(y) = 0$ is an excellent decision and we have $R(0, \delta_2) = 0$. However, if θ differs from zero by very much, it is equally clear that $\delta_2 = 0$ is a poor decision. For example, if, in fact, $\theta = 2$, $R(2, \delta_2) = 4 > R(2, \delta_1) = \frac{1}{25}$. In general, we see that $R(\theta, \delta_2) < R(\theta, \delta_1)$, provided that $-\frac{1}{5} < \theta < \frac{1}{5}$, and that otherwise $R(\theta, \delta_2) \geq R(\theta, \delta_1)$. That is, one of these decision functions is better than the other for some values of θ , while the other decision function is better for other values of θ . If, however, we had restricted our consideration to decision functions δ such that $E[\delta(Y)] = \theta$ for all values of θ , $\theta \in \Omega$, then the decision function $\delta_2(y) = 0$ is not allowed. Under this restriction and with the given $\mathcal{L}[\theta, \delta(y)]$, the risk function is the variance of the unbiased estimator $\delta(Y)$, and we are confronted with the problem of finding the MVUE. Later in this chapter we show that the solution is $\delta(y) = y = \bar{x}$.

Suppose, however, that we do not want to restrict ourselves to decision functions δ , such that $E[\delta(Y)] = \theta$ for all values of θ , $\theta \in \Omega$. Instead, let us say that the decision function that minimizes the maximum of the risk function is the best decision function. Because, in this example, $R(\theta, \delta_2) = \theta^2$ is unbounded, $\delta_2(y) = 0$ is not, in accordance with this criterion, a good decision function. On the other hand, with $-\infty < \theta < \infty$, we have

$$\max_{\theta} R(\theta, \delta_1) = \max_{\theta} \left(\frac{1}{25} \right) = \frac{1}{25}.$$

Accordingly, $\delta_1(y) = y = \bar{x}$ seems to be a very good decision in accordance with this criterion because $\frac{1}{25}$ is small. As a matter of fact, it can be proved that δ_1 is the best decision function, as measured by the **minimax criterion**, when the loss function is $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. ■

In this example we illustrated the following:

1. Without some restriction on the decision function, it is difficult to find a decision function that has a risk function which is uniformly less than the risk function of another decision.
2. One principle of selecting a best decision function is called the **minimax principle**. This principle may be stated as follows: If the decision function given by $\delta_0(y)$ is such that, for all $\theta \in \Omega$,

$$\max_{\theta} R[\theta, \delta_0(y)] \leq \max_{\theta} R[\theta, \delta(y)]$$

for every other decision function $\delta(y)$, then $\delta_0(y)$ is called a **minimax decision function**.

With the restriction $E[\delta(Y)] = \theta$ and the loss function $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$, the decision function that minimizes the risk function yields an unbiased estimator with minimum variance. If, however, the restriction $E[\delta(Y)] = \theta$ is replaced by some other condition, the decision function $\delta(Y)$, if it exists, which minimizes $E\{[\theta - \delta(Y)]^2\}$ uniformly in θ is sometimes called the **minimum mean-squared-error estimator**. Exercises 7.1.6–7.1.8 provide examples of this type of estimator.

There are two additional observations about decision rules and loss functions that should be made at this point. First, since Y is a statistic, the decision rule

$\delta(Y)$ is also a statistic, and we could have started directly with a decision rule based on the observations in a random sample, say, $\delta_1(X_1, X_2, \dots, X_n)$. The risk function is then given by

$$\begin{aligned} R(\theta, \delta_1) &= E\{\mathcal{L}[\theta, \delta_1(X_1, \dots, X_n)]\} \\ &= \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta_1(x_1, \dots, x_n)] f(x_1; \theta) \cdots f(x_n; \theta) dx_1 \cdots dx_n \end{aligned}$$

if the random sample arises from a continuous-type distribution. We do not do this, because, as we show in this chapter, it is rather easy to find a good statistic, say Y , upon which to base all of the statistical inferences associated with a particular model. Thus we thought it more appropriate to start with a statistic that would be familiar, like the mle $Y = \bar{X}$ in Example 7.1.2. The second decision rule of that example could be written $\delta_2(X_1, X_2, \dots, X_n) = 0$, a constant no matter what values of X_1, X_2, \dots, X_n are observed.

The second observation is that we have only used one loss function, namely, the **squared-error loss function** $\mathcal{L}(\theta, \delta) = (\theta - \delta)^2$. The **absolute-error loss function** $\mathcal{L}(\theta, \delta) = |\theta - \delta|$ is another popular one. The loss function defined by

$$\begin{aligned} \mathcal{L}(\theta, \delta) &= 0, \quad |\theta - \delta| \leq a, \\ &= b, \quad |\theta - \delta| > a, \end{aligned}$$

where a and b are positive constants, is sometimes referred to as the *goalpost loss function*. The reason for this terminology is that football fans recognize that it is similar to kicking a field goal: There is no loss (actually a three-point gain) if within a units of the middle but b units of loss (zero points awarded) if outside that restriction. In addition, loss functions can be asymmetric as well as symmetric, as the three previous ones have been. That is, for example, it might be more costly to underestimate the value of θ than to overestimate it. (Many of us think about this type of loss function when estimating the time it takes us to reach an airport to catch a plane.) Some of these loss functions are considered when studying Bayesian estimates in Chapter 11.

Let us close this section with an interesting illustration that raises a question leading to the likelihood principle, which many statisticians believe is a quality characteristic that estimators should enjoy. Suppose that two statisticians, A and B , observe 10 independent trials of a random experiment ending in success or failure. Let the probability of success on each trial be θ , where $0 < \theta < 1$. Let us say that each statistician observes one success in these 10 trials. Suppose, however, that A had decided to take $n = 10$ such observations in advance and found only one success, while B had decided to take as many observations as needed to get the first success, which happened on the 10th trial. The model of A is that Y is $b(n = 10, \theta)$ and $y = 1$ is observed. On the other hand, B is considering the random variable Z that has a geometric pmf $g(z) = (1 - \theta)^{z-1} \theta$, $z = 1, 2, 3, \dots$, and $z = 10$ is observed. In either case, an estimate of θ could be the relative frequency of success given by

$$\frac{y}{n} = \frac{1}{z} = \frac{1}{10}.$$

Let us observe, however, that one of the corresponding estimators, Y/n and $1/Z$, is biased. We have

$$E\left(\frac{Y}{10}\right) = \frac{1}{10}E(Y) = \frac{1}{10}(10\theta) = \theta,$$

while

$$\begin{aligned} E\left(\frac{1}{Z}\right) &= \sum_{z=1}^{\infty} \frac{1}{z}(1-\theta)^{z-1}\theta \\ &= \theta + \frac{1}{2}(1-\theta)\theta + \frac{1}{3}(1-\theta)^2\theta + \dots > \theta. \end{aligned}$$

That is, $1/Z$ is a biased estimator while $Y/10$ is unbiased. Thus A is using an unbiased estimator while B is not. Should we adjust B 's estimator so that it, too, is unbiased?

It is interesting to note that if we maximize the two respective likelihood functions, namely,

$$L_1(\theta) = \binom{10}{y} \theta^y (1-\theta)^{10-y}$$

and

$$L_2(\theta) = (1-\theta)^{z-1}\theta,$$

with $n = 10$, $y = 1$, and $z = 10$, we get exactly the same answer, $\hat{\theta} = \frac{1}{10}$. This must be the case, because in each situation we are maximizing $(1-\theta)^9\theta$. Many statisticians believe that this is the way it should be and accordingly adopt the *likelihood principle*:

Suppose two different sets of data from possibly two different random experiments lead to respective likelihood ratios, $L_1(\theta)$ and $L_2(\theta)$, that are proportional to each other. These two data sets provide the same information about the parameter θ and a statistician should obtain the same estimate of θ from either.

In our special illustration, we note that $L_1(\theta) \propto L_2(\theta)$, and the likelihood principle states that statisticians A and B should make the same inference. Thus believers in the likelihood principle would not adjust the second estimator to make it unbiased.

EXERCISES

7.1.1. Show that the mean \bar{X} of a random sample of size n from a distribution having pdf $f(x;\theta) = (1/\theta)e^{-(x/\theta)}$, $0 < x < \infty$, $0 < \theta < \infty$, zero elsewhere, is an unbiased estimator of θ and has variance θ^2/n .

7.1.2. Let X_1, X_2, \dots, X_n denote a random sample from a normal distribution with mean zero and variance θ , $0 < \theta < \infty$. Show that $\sum_1^n X_i^2/n$ is an unbiased estimator of θ and has variance $2\theta^2/n$.

7.1.3. Let $Y_1 < Y_2 < Y_3$ be the order statistics of a random sample of size 3 from the uniform distribution having pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, $0 < \theta < \infty$, zero elsewhere. Show that $4Y_1$, $2Y_2$, and $\frac{4}{3}Y_3$ are all unbiased estimators of θ . Find the variance of each of these unbiased estimators.

7.1.4. Let Y_1 and Y_2 be two independent unbiased estimators of θ . Assume that the variance of Y_1 is twice the variance of Y_2 . Find the constants k_1 and k_2 so that $k_1Y_1 + k_2Y_2$ is an unbiased estimator with the smallest possible variance for such a linear combination.

7.1.5. In Example 7.1.2 of this section, take $\mathcal{L}[\theta, \delta(y)] = |\theta - \delta(y)|$. Show that $R(\theta, \delta_1) = \frac{1}{5}\sqrt{2/\pi}$ and $R(\theta, \delta_2) = |\theta|$. Of these two decision functions δ_1 and δ_2 , which yields the smaller maximum risk?

7.1.6. Let X_1, X_2, \dots, X_n denote a random sample from a Poisson distribution with parameter θ , $0 < \theta < \infty$. Let $Y = \sum_1^n X_i$ and let $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. If we restrict our considerations to decision functions of the form $\delta(y) = b + y/n$, where b does not depend on y , show that $R(\theta, \delta) = b^2 + \theta/n$. What decision function of this form yields a uniformly smaller risk than every other decision function of this form? With this solution, say δ , and $0 < \theta < \infty$, determine $\max_{\theta} R(\theta, \delta)$ if it exists.

7.1.7. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\mu, \theta)$, $0 < \theta < \infty$, where μ is unknown. Let $Y = \sum_1^n (X_i - \bar{X})^2/n$ and let $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. If we consider decision functions of the form $\delta(y) = by$, where b does not depend upon y , show that $R(\theta, \delta) = (\theta^2/n^2)[(n^2 - 1)b^2 - 2n(n - 1)b + n^2]$. Show that $b = n/(n + 1)$ yields a minimum risk decision function of this form. Note that $nY/(n + 1)$ is not an unbiased estimator of θ . With $\delta(y) = ny/(n + 1)$ and $0 < \theta < \infty$, determine $\max_{\theta} R(\theta, \delta)$ if it exists.

7.1.8. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $b(1, \theta)$, $0 \leq \theta \leq 1$. Let $Y = \sum_1^n X_i$ and let $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. Consider decision functions of the form $\delta(y) = by$, where b does not depend upon y . Prove that $R(\theta, \delta) = b^2 n \theta (1 - \theta) + (bn - 1)^2 \theta^2$. Show that

$$\max_{\theta} R(\theta, \delta) = \frac{b^4 n^2}{4[b^2 n - (bn - 1)^2]},$$

provided that the value b is such that $b^2 n > (bn - 1)^2$. Prove that $b = 1/n$ does not minimize $\max_{\theta} R(\theta, \delta)$.

7.1.9. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with mean $\theta > 0$.

- (a) Statistician A observes the sample to be the values x_1, x_2, \dots, x_n with sum $y = \sum x_i$. Find the mle of θ .
- (b) Statistician B loses the sample values x_1, x_2, \dots, x_n but remembers the sum y_1 and the fact that the sample arose from a Poisson distribution. Thus B decides to create some fake observations, which he calls z_1, z_2, \dots, z_n (as

he knows they will probably not equal the original x -values) as follows. He notes that the conditional probability of independent Poisson random variables Z_1, Z_2, \dots, Z_n being equal to z_1, z_2, \dots, z_n , given $\sum z_i = y_1$, is

$$\frac{\frac{\theta^{z_1} e^{-\theta}}{z_1!} \frac{\theta^{z_2} e^{-\theta}}{z_2!} \cdots \frac{\theta^{z_n} e^{-\theta}}{z_n!}}{\frac{(n\theta)^{y_1} e^{-n\theta}}{y_1!}} = \frac{y_1!}{z_1! z_2! \cdots z_n!} \left(\frac{1}{n}\right)^{z_1} \left(\frac{1}{n}\right)^{z_2} \cdots \left(\frac{1}{n}\right)^{z_n}$$

since $Y_1 = \sum Z_i$ has a Poisson distribution with mean $n\theta$. The latter distribution is multinomial with y_1 independent trials, each terminating in one of n mutually exclusive and exhaustive ways, each of which has the same probability $1/n$. Accordingly, B runs such a multinomial experiment y_1 independent trials and obtains z_1, z_2, \dots, z_n . Find the likelihood function using these z -values. Is it proportional to that of statistician A ?

Hint: Here the likelihood function is the product of this conditional pdf and the pdf of $Y_1 = \sum Z_i$.

7.2 A Sufficient Statistic for a Parameter

Suppose that X_1, X_2, \dots, X_n is a random sample from a distribution that has pdf $f(x; \theta)$, $\theta \in \Omega$. In Chapters 4 and 6, we constructed statistics to make statistical inferences as illustrated by point and interval estimation and tests of statistical hypotheses. We note that a statistic, for example, $Y = u(X_1, X_2, \dots, X_n)$, is a form of data reduction. To illustrate, instead of listing all of the individual observations X_1, X_2, \dots, X_n , we might prefer to give only the sample mean \bar{X} or the sample variance S^2 . Thus statisticians look for ways of reducing a set of data so that these data can be more easily understood without losing the meaning associated with the entire set of observations.

It is interesting to note that a statistic $Y = u(X_1, X_2, \dots, X_n)$ really partitions the sample space of X_1, X_2, \dots, X_n . For illustration, suppose we say that the sample was observed and $\bar{x} = 8.32$. There are many points in the sample space which have that same mean of 8.32, and we can consider them as belonging to the set $\{(x_1, x_2, \dots, x_n) : \bar{x} = 8.32\}$. As a matter of fact, all points on the hyperplane

$$x_1 + x_2 + \cdots + x_n = (8.32)n$$

yield the mean of $\bar{x} = 8.32$, so this hyperplane is the set. However, there are many values that \bar{X} can take, and thus there are many such sets. So, in this sense, the sample mean \bar{X} , or any statistic $Y = u(X_1, X_2, \dots, X_n)$, partitions the sample space into a collection of sets.

Often in the study of statistics the parameter θ of the model is unknown; thus, we need to make some statistical inference about it. In this section we consider a statistic denoted by $Y_1 = u_1(X_1, X_2, \dots, X_n)$, which we call a **sufficient statistic** and which we find is good for making those inferences. This sufficient statistic partitions the sample space in such a way that, given

$$(X_1, X_2, \dots, X_n) \in \{(x_1, x_2, \dots, x_n) : u_1(x_1, x_2, \dots, x_n) = y_1\},$$

the conditional probability of X_1, X_2, \dots, X_n does not depend upon θ . Intuitively, this means that once the set determined by $Y_1 = y_1$ is fixed, the distribution of another statistic, say $Y_2 = u_2(X_1, X_2, \dots, X_n)$, does not depend upon the parameter θ because the conditional distribution of X_1, X_2, \dots, X_n does not depend upon θ . Hence it is impossible to use Y_2 , given $Y_1 = y_1$, to make a statistical inference about θ . So, in a sense, Y_1 *exhausts* all the information about θ that is contained in the sample. This is why we call $Y_1 = u_1(X_1, X_2, \dots, X_n)$ a sufficient statistic.

To understand clearly the definition of a sufficient statistic for a parameter θ , we start with an illustration.

Example 7.2.1. Let X_1, X_2, \dots, X_n denote a random sample from the distribution that has pmf

$$f(x; \theta) = \begin{cases} \theta^x (1-\theta)^{1-x} & x = 0, 1; \quad 0 < \theta < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

The statistic $Y_1 = X_1 + X_2 + \dots + X_n$ has the pmf

$$f_{Y_1}(y_1; \theta) = \begin{cases} \binom{n}{y_1} \theta^{y_1} (1-\theta)^{n-y_1} & y_1 = 0, 1, \dots, n \\ 0 & \text{elsewhere.} \end{cases}$$

What is the conditional probability

$$P(X_1 = x_1, X_2 = x_2, \dots, X_n = x_n | Y_1 = y_1) = P(A|B),$$

say, where $y_1 = 0, 1, 2, \dots, n$? Unless the sum of the integers x_1, x_2, \dots, x_n (each of which equals zero or 1) is equal to y_1 , the conditional probability obviously equals zero because $A \cap B = \emptyset$. But in the case $y_1 = \sum x_i$, we have that $A \subset B$, so that $A \cap B = A$ and $P(A|B) = P(A)/P(B)$; thus, the conditional probability equals

$$\begin{aligned} \frac{\theta^{x_1} (1-\theta)^{1-x_1} \theta^{x_2} (1-\theta)^{1-x_2} \dots \theta^{x_n} (1-\theta)^{1-x_n}}{\binom{n}{y_1} \theta^{y_1} (1-\theta)^{n-y_1}} &= \frac{\theta^{\sum x_i} (1-\theta)^{n-\sum x_i}}{\binom{n}{\sum x_i} \theta^{\sum x_i} (1-\theta)^{n-\sum x_i}} \\ &= \frac{1}{\binom{n}{\sum x_i}}. \end{aligned}$$

Since $y_1 = x_1 + x_2 + \dots + x_n$ equals the number of ones in the n independent trials, this is the conditional probability of selecting a particular arrangement of y_1 ones and $(n - y_1)$ zeros. Note that this conditional probability does *not* depend upon the value of the parameter θ . ■

In general, let $f_{Y_1}(y_1; \theta)$ be the pmf of the statistic $Y_1 = u_1(X_1, X_2, \dots, X_n)$, where X_1, X_2, \dots, X_n is a random sample arising from a distribution of the discrete type having pmf $f(x; \theta)$, $\theta \in \Omega$. The conditional probability of $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$, given $Y_1 = y_1$, equals

$$\frac{f(x_1; \theta) f(x_2; \theta) \dots f(x_n; \theta)}{f_{Y_1}[u_1(x_1, x_2, \dots, x_n); \theta]},$$

provided that x_1, x_2, \dots, x_n are such that the fixed $y_1 = u_1(x_1, x_2, \dots, x_n)$, and equals zero otherwise. We say that $Y_1 = u_1(X_1, X_2, \dots, X_n)$ is a *sufficient statistic* for θ if and only if this ratio does not depend upon θ . While, with distributions of the continuous type, we cannot use the same argument, we do, in this case, accept the fact that if this ratio does not depend upon θ , then the conditional distribution of X_1, X_2, \dots, X_n , given $Y_1 = y_1$, does not depend upon θ . Thus, in both cases, we use the same definition of a sufficient statistic for θ .

Definition 7.2.1. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution that has pdf or pmf $f(x; \theta)$, $\theta \in \Omega$. Let $Y_1 = u_1(X_1, X_2, \dots, X_n)$ be a statistic whose pdf or pmf is $f_{Y_1}(y_1; \theta)$. Then Y_1 is a **sufficient statistic** for θ if and only if

$$\frac{f(x_1; \theta) f(x_2; \theta) \cdots f(x_n; \theta)}{f_{Y_1}[u_1(x_1, x_2, \dots, x_n); \theta]} = H(x_1, x_2, \dots, x_n),$$

where $H(x_1, x_2, \dots, x_n)$ does not depend upon $\theta \in \Omega$.

Remark 7.2.1. In most cases in this book, X_1, X_2, \dots, X_n represent the observations of a random sample; that is, they are iid. It is not necessary, however, in more general situations, that these random variables be independent; as a matter of fact, they do not need to be identically distributed. Thus, more generally, the definition of sufficiency of a statistic $Y_1 = u_1(X_1, X_2, \dots, X_n)$ would be extended to read that

$$\frac{f(x_1, x_2, \dots, x_n; \theta)}{f_{Y_1}[u_1(x_1, x_2, \dots, x_n); \theta]} = H(x_1, x_2, \dots, x_n)$$

does not depend upon $\theta \in \Omega$, where $f(x_1, x_2, \dots, x_n; \theta)$ is the joint pdf or pmf of X_1, X_2, \dots, X_n . There are even a few situations in which we need an extension like this one in this book. ■

We now give two examples that are illustrative of the definition.

Example 7.2.2. Let X_1, X_2, \dots, X_n be a random sample from a gamma distribution with $\alpha = 2$ and $\beta = \theta > 0$. Because the mgf associated with this distribution is given by $M(t) = (1 - \theta t)^{-2}$, $t < 1/\theta$, the mgf of $Y_1 = \sum_{i=1}^n X_i$ is

$$\begin{aligned} E[e^{t(X_1 + X_2 + \dots + X_n)}] &= E(e^{tX_1})E(e^{tX_2})\cdots E(e^{tX_n}) \\ &= [(1 - \theta t)^{-2}]^n = (1 - \theta t)^{-2n}. \end{aligned}$$

Thus Y_1 has a gamma distribution with $\alpha = 2n$ and $\beta = \theta$, so that its pdf is

$$f_{Y_1}(y_1; \theta) = \begin{cases} \frac{1}{\Gamma(2n)\theta^{2n}} y_1^{2n-1} e^{-y_1/\theta} & 0 < y_1 < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Thus we have

$$\frac{\left[\frac{x_1^{2-1} e^{-x_1/\theta}}{\Gamma(2)\theta^2} \right] \left[\frac{x_2^{2-1} e^{-x_2/\theta}}{\Gamma(2)\theta^2} \right] \cdots \left[\frac{x_n^{2-1} e^{-x_n/\theta}}{\Gamma(2)\theta^2} \right]}{(x_1 + x_2 + \dots + x_n)^{2n-1} e^{-(x_1+x_2+\dots+x_n)/\theta}} = \frac{\Gamma(2n)}{[\Gamma(2)]^n} \frac{x_1 x_2 \cdots x_n}{(x_1 + x_2 + \dots + x_n)^{2n-1}},$$

$$\Gamma(2n)\theta^{2n}$$

where $0 < x_i < \infty$, $i = 1, 2, \dots, n$. Since this ratio does not depend upon θ , the sum Y_1 is a sufficient statistic for θ . ■

Example 7.2.3. Let $Y_1 < Y_2 < \dots < Y_n$ denote the order statistics of a random sample of size n from the distribution with pdf

$$f(x; \theta) = e^{-(x-\theta)} I_{(\theta, \infty)}(x).$$

Here we use the indicator function of a set A defined by

$$I_A(x) = \begin{cases} 1 & x \in A \\ 0 & x \notin A. \end{cases}$$

This means, of course, that $f(x; \theta) = e^{-(x-\theta)}$, $\theta < x < \infty$, zero elsewhere. The pdf of $Y_1 = \min(X_i)$ is

$$f_{Y_1}(y_1; \theta) = ne^{-n(y_1-\theta)} I_{(\theta, \infty)}(y_1).$$

Note that $\theta < \min\{x_i\}$ if and only if $\theta < x_i$, for all $i = 1, \dots, n$. Notationally this can be expressed as $I_{(\theta, \infty)}(\min x_i) = \prod_{i=1}^n I_{(\theta, \infty)}(x_i)$. Thus we have that

$$\frac{\prod_{i=1}^n e^{-(x_i-\theta)} I_{(\theta, \infty)}(x_i)}{ne^{-n(\min x_i-\theta)} I_{(\theta, \infty)}(\min x_i)} = \frac{e^{-x_1-x_2-\dots-x_n}}{ne^{-n \min x_i}}.$$

Since this ratio does not depend upon θ , the first order statistic Y_1 is a sufficient statistic for θ . ■

If we are to show by means of the definition that a certain statistic Y_1 is or is not a sufficient statistic for a parameter θ , we must first of all know the pdf of Y_1 , say $f_{Y_1}(y_1; \theta)$. In many instances it may be quite difficult to find this pdf. Fortunately, this problem can be avoided if we prove the following **factorization theorem** of Neyman.

Theorem 7.2.1 (Neyman). *Let X_1, X_2, \dots, X_n denote a random sample from a distribution that has pdf or pmf $f(x; \theta)$, $\theta \in \Omega$. The statistic $Y_1 = u_1(X_1, \dots, X_n)$ is a sufficient statistic for θ if and only if we can find two nonnegative functions, k_1 and k_2 , such that*

$$f(x_1; \theta)f(x_2; \theta)\cdots f(x_n; \theta) = k_1[u_1(x_1, x_2, \dots, x_n); \theta]k_2(x_1, x_2, \dots, x_n), \quad (7.2.1)$$

where $k_2(x_1, x_2, \dots, x_n)$ does not depend upon θ .

Proof. We shall prove the theorem when the random variables are of the continuous type. Assume that the factorization is as stated in the theorem. In our proof we shall make the one-to-one transformation $y_1 = u_1(x_1, x_2, \dots, x_n)$, $y_2 = u_2(x_1, x_2, \dots, x_n), \dots, y_n = u_n(x_1, x_2, \dots, x_n)$ having the inverse functions $x_1 = w_1(y_1, y_2, \dots, y_n)$, $x_2 = w_2(y_1, y_2, \dots, y_n)$, $\dots, x_n = w_n(y_1, y_2, \dots, y_n)$ and Jacobian J ; see the note after the proof. The pdf of the statistic Y_1, Y_2, \dots, Y_n is then given by

$$g(y_1, y_2, \dots, y_n; \theta) = k_1(y_1; \theta)k_2(w_1, w_2, \dots, w_n)|J|,$$

where $w_i = w_i(y_1, y_2, \dots, y_n)$, $i = 1, 2, \dots, n$. The pdf of Y_1 , say $f_{Y_1}(y_1; \theta)$, is given by

$$\begin{aligned} f_{Y_1}(y_1; \theta) &= \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} g(y_1, y_2, \dots, y_n; \theta) dy_2 \cdots dy_n \\ &= k_1(y_1; \theta) \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} |J| k_2(w_1, w_2, \dots, w_n) dy_2 \cdots dy_n. \end{aligned}$$

Now the function k_2 does not depend upon θ , nor is θ involved in either the Jacobian J or the limits of integration. Hence the $(n - 1)$ -fold integral in the right-hand member of the preceding equation is a function of y_1 alone, for example, $m(y_1)$. Thus

$$f_{Y_1}(y_1; \theta) = k_1(y_1; \theta)m(y_1).$$

If $m(y_1) = 0$, then $f_{Y_1}(y_1; \theta) = 0$. If $m(y_1) > 0$, we can write

$$k_1[u_1(x_1, x_2, \dots, x_n); \theta] = \frac{f_{Y_1}[u_1(x_1, \dots, x_n); \theta]}{m[u_1(x_1, \dots, x_n)]},$$

and the assumed factorization becomes

$$f(x_1; \theta) \cdots f(x_n; \theta) = f_{Y_1}[u_1(x_1, \dots, x_n); \theta] \frac{k_2(x_1, \dots, x_n)}{m[u_1(x_1, \dots, x_n)]}.$$

Since neither the function k_2 nor the function m depends upon θ , then in accordance with the definition, Y_1 is a sufficient statistic for the parameter θ .

Conversely, if Y_1 is a sufficient statistic for θ , the factorization can be realized by taking the function k_1 to be the pdf of Y_1 , namely, the function f_{Y_1} . This completes the proof of the theorem. ■

Note that the assumption of a one-to-one transformation made in the proof is not needed; see Lehmann (1986) for a more rigorous proof. This theorem characterizes sufficiency and, as the following examples show, is usually much easier to work with than the definition of sufficiency.

Example 7.2.4. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta, \sigma^2)$, $-\infty < \theta < \infty$, where the variance $\sigma^2 > 0$ is known. If $\bar{x} = \sum_{i=1}^n x_i/n$, then

$$\sum_{i=1}^n (x_i - \theta)^2 = \sum_{i=1}^n [(x_i - \bar{x}) + (\bar{x} - \theta)]^2 = \sum_{i=1}^n (x_i - \bar{x})^2 + n(\bar{x} - \theta)^2$$

because

$$2 \sum_{i=1}^n (x_i - \bar{x})(\bar{x} - \theta) = 2(\bar{x} - \theta) \sum_{i=1}^n (x_i - \bar{x}) = 0.$$

Thus the joint pdf of X_1, X_2, \dots, X_n may be written

$$\begin{aligned} & \left(\frac{1}{\sigma\sqrt{2\pi}} \right)^n \exp \left[- \sum_{i=1}^n (x_i - \theta)^2 / 2\sigma^2 \right] \\ & = \{ \exp[-n(\bar{x} - \theta)^2 / 2\sigma^2] \} \left\{ \frac{\exp \left[- \sum_{i=1}^n (x_i - \bar{x})^2 / 2\sigma^2 \right]}{(\sigma\sqrt{2\pi})^n} \right\}. \end{aligned}$$

Because the first factor of the right-hand member of this equation depends upon x_1, x_2, \dots, x_n only through \bar{x} , and the second factor does not depend upon θ , the factorization theorem implies that the mean \bar{X} of the sample is, for any particular value of σ^2 , a sufficient statistic for θ , the mean of the normal distribution. ■

We could have used the definition in the preceding example because we know that \bar{X} is $N(\theta, \sigma^2/n)$. Let us now consider an example in which the use of the definition is inappropriate.

Example 7.2.5. Let X_1, X_2, \dots, X_n denote a random sample from a distribution with pdf

$$f(x; \theta) = \begin{cases} \theta x^{\theta-1} & 0 < x < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

where $0 < \theta$. The joint pdf of X_1, X_2, \dots, X_n is

$$\theta^n \left(\prod_{i=1}^n x_i \right)^{\theta-1} = \left[\theta^n \left(\prod_{i=1}^n x_i \right)^\theta \right] \left(\frac{1}{\prod_{i=1}^n x_i} \right),$$

where $0 < x_i < 1$, $i = 1, 2, \dots, n$. In the factorization theorem, let

$$k_1[u_1(x_1, x_2, \dots, x_n); \theta] = \theta^n \left(\prod_{i=1}^n x_i \right)^\theta$$

and

$$k_2(x_1, x_2, \dots, x_n) = \frac{1}{\prod_{i=1}^n x_i}.$$

Since $k_2(x_1, x_2, \dots, x_n)$ does not depend upon θ , the product $\prod_{i=1}^n X_i$ is a sufficient statistic for θ . ■

There is a tendency for some readers to apply incorrectly the factorization theorem in those instances in which the domain of positive probability density depends upon the parameter θ . This is due to the fact that they do not give proper consideration to the domain of the function $k_2(x_1, x_2, \dots, x_n)$. This is illustrated in the next example.

Example 7.2.6. In Example 7.2.3 with $f(x; \theta) = e^{-(x-\theta)}I_{(\theta, \infty)}(x)$, it was found that the first order statistic Y_1 is a sufficient statistic for θ . To illustrate our point about not considering the domain of the function, take $n = 3$ and note that

$$e^{-(x_1-\theta)}e^{-(x_2-\theta)}e^{-(x_3-\theta)} = [e^{-3 \max x_i + 3\theta}][e^{-x_1-x_2-x_3+3 \max x_i}]$$

or a similar expression. Certainly, in the latter formula, there is no θ in the second factor and it might be assumed that $Y_3 = \max X_i$ is a sufficient statistic for θ . Of course, this is incorrect because we should have written the joint pdf of X_1, X_2, X_3 as

$$\prod_{i=1}^3 [e^{-(x_i-\theta)}I_{(\theta, \infty)}(x_i)] = [e^{3\theta}I_{(\theta, \infty)}(\min x_i)] \left[\exp \left\{ - \sum_{i=1}^3 x_i \right\} \right]$$

because $I_{(\theta, \infty)}(\min x_i) = I_{(\theta, \infty)}(x_1)I_{(\theta, \infty)}(x_2)I_{(\theta, \infty)}(x_3)$. A similar statement cannot be made with $\max x_i$. Thus $Y_1 = \min X_i$ is the sufficient statistic for θ , not $Y_3 = \max X_i$. ■

EXERCISES

7.2.1. Let X_1, X_2, \dots, X_n be iid $N(0, \theta)$, $0 < \theta < \infty$. Show that $\sum_1^n X_i^2$ is a sufficient statistic for θ .

7.2.2. Prove that the sum of the observations of a random sample of size n from a Poisson distribution having parameter θ , $0 < \theta < \infty$, is a sufficient statistic for θ .

7.2.3. Show that the n th order statistic of a random sample of size n from the uniform distribution having pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, $0 < \theta < \infty$, zero elsewhere, is a sufficient statistic for θ . Generalize this result by considering the pdf $f(x; \theta) = Q(\theta)M(x)$, $0 < x < \theta$, $0 < \theta < \infty$, zero elsewhere. Here, of course,

$$\int_0^\theta M(x) dx = \frac{1}{Q(\theta)}.$$

7.2.4. Let X_1, X_2, \dots, X_n be a random sample of size n from a geometric distribution that has pmf $f(x; \theta) = (1 - \theta)^x \theta$, $x = 0, 1, 2, \dots$, $0 < \theta < 1$, zero elsewhere. Show that $\sum_1^n X_i$ is a sufficient statistic for θ .

7.2.5. Show that the sum of the observations of a random sample of size n from a gamma distribution that has pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, $0 < \theta < \infty$, zero elsewhere, is a sufficient statistic for θ .

7.2.6. Let X_1, X_2, \dots, X_n be a random sample of size n from a beta distribution with parameters $\alpha = \theta$ and $\beta = 5$. Show that the product $X_1 X_2 \cdots X_n$ is a sufficient statistic for θ .

7.2.7. Show that the product of the sample observations is a sufficient statistic for $\theta > 0$ if the random sample is taken from a gamma distribution with parameters $\alpha = \theta$ and $\beta = 6$.

7.2.8. What is the sufficient statistic for θ if the sample arises from a beta distribution in which $\alpha = \beta = \theta > 0$?

7.2.9. We consider a random sample X_1, X_2, \dots, X_n from a distribution with pdf $f(x; \theta) = (1/\theta) \exp(-x/\theta)$, $0 < x < \infty$, zero elsewhere, where $0 < \theta$. Possibly, in a life-testing situation, however, we only observe the first r order statistics $Y_1 < Y_2 < \dots < Y_r$.

- (a) Record the joint pdf of these order statistics and denote it by $L(\theta)$.
- (b) Under these conditions, find the mle, $\hat{\theta}$, by maximizing $L(\theta)$.
- (c) Find the mgf and pdf of $\hat{\theta}$.
- (d) With a slight extension of the definition of sufficiency, is $\hat{\theta}$ a sufficient statistic?

7.3 Properties of a Sufficient Statistic

Suppose X_1, X_2, \dots, X_n is a random sample on a random variable with pdf or pmf $f(x; \theta)$, where $\theta \in \Omega$. In this section we discuss how sufficiency is used to determine MVUEs. First note that a sufficient estimate is not unique in any sense. For if $Y_1 = u_1(X_1, X_2, \dots, X_n)$ is a sufficient statistic and $Y_2 = g(Y_1)$ is a statistic, where $g(x)$ is a one-to-one function, then

$$\begin{aligned} f(x_1; \theta)f(x_2; \theta)\cdots f(x_n; \theta) &= k_1[u_1(y_1); \theta]k_2(x_1, x_2, \dots, x_n) \\ &= k_1[u_1(g^{-1}(y_2)); \theta]k_2(x_1, x_2, \dots, x_n); \end{aligned}$$

hence, by the factorization theorem, Y_2 is also sufficient. However, as the theorem below shows, sufficiency can lead to a best point estimate.

We first refer back to Theorem 2.3.1 of Section 2.3: If X_1 and X_2 are random variables such that the variance of X_2 exists, then

$$E[X_2] = E[E(X_2|X_1)]$$

and

$$\text{Var}(X_2) \geq \text{Var}[E(X_2|X_1)].$$

For the adaptation in the context of sufficient statistics, we let the sufficient statistic Y_1 be X_1 and Y_2 , an unbiased statistic of θ , be X_2 . Thus, with $E(Y_2|y_1) = \varphi(y_1)$, we have

$$\theta = E(Y_2) = E[\varphi(Y_1)]$$

and

$$\text{Var}(Y_2) \geq \text{Var}[\varphi(Y_1)].$$

That is, through this conditioning, the function $\varphi(Y_1)$ of the sufficient statistic Y_1 is an unbiased estimator of θ having a smaller variance than that of the unbiased estimator Y_2 . We summarize this discussion more formally in the following theorem, which can be attributed to Rao and Blackwell.

Theorem 7.3.1 (Rao–Blackwell). *Let X_1, X_2, \dots, X_n , n a fixed positive integer, denote a random sample from a distribution (continuous or discrete) that has pdf or pmf $f(x; \theta)$, $\theta \in \Omega$. Let $Y_1 = u_1(X_1, X_2, \dots, X_n)$ be a sufficient statistic for θ , and let $Y_2 = u_2(X_1, X_2, \dots, X_n)$, not a function of Y_1 alone, be an unbiased estimator of θ . Then $E(Y_2|y_1) = \varphi(y_1)$ defines a statistic $\varphi(Y_1)$. This statistic $\varphi(Y_1)$ is a function of the sufficient statistic for θ ; it is an unbiased estimator of θ ; and its variance is less than or equal to that of Y_2 .*

This theorem tells us that in our search for an MVUE of a parameter, we may, if a sufficient statistic for the parameter exists, restrict that search to functions of the sufficient statistic. For if we begin with an unbiased estimator Y_2 alone, then we can always improve on this by computing $E(Y_2|y_1) = \varphi(y_1)$ so that $\varphi(Y_1)$ is an unbiased estimator with a smaller variance than that of Y_2 .

After Theorem 7.3.1, many students believe that it is necessary to find first some unbiased estimator Y_2 in their search for $\varphi(Y_1)$, an unbiased estimator of θ based upon the sufficient statistic Y_1 . This is not the case at all, and Theorem 7.3.1 simply convinces us that we can restrict our search for a best estimator to functions of Y_1 . Furthermore, there is a connection between sufficient statistics and maximum likelihood estimates, as shown in the following theorem:

Theorem 7.3.2. *Let X_1, X_2, \dots, X_n denote a random sample from a distribution that has pdf or pmf $f(x; \theta)$, $\theta \in \Omega$. If a sufficient statistic $Y_1 = u_1(X_1, X_2, \dots, X_n)$ for θ exists and if a maximum likelihood estimator $\hat{\theta}$ of θ also exists uniquely, then $\hat{\theta}$ is a function of $Y_1 = u_1(X_1, X_2, \dots, X_n)$.*

Proof. Let $f_{Y_1}(y_1; \theta)$ be the pdf or pmf of Y_1 . Then by the definition of sufficiency, the likelihood function

$$\begin{aligned} L(\theta; x_1, x_2, \dots, x_n) &= f(x_1; \theta)f(x_2; \theta) \cdots f(x_n; \theta) \\ &= f_{Y_1}[u_1(x_1, x_2, \dots, x_n); \theta]H(x_1, x_2, \dots, x_n), \end{aligned}$$

where $H(x_1, x_2, \dots, x_n)$ does not depend upon θ . Thus L and f_{Y_1} , as functions of θ , are maximized simultaneously. Since there is one and only one value of θ that maximizes L and hence $f_{Y_1}[u_1(x_1, x_2, \dots, x_n); \theta]$, that value of θ must be a function of $u_1(x_1, x_2, \dots, x_n)$. Thus the mle $\hat{\theta}$ is a function of the sufficient statistic $Y_1 = u_1(X_1, X_2, \dots, X_n)$. ■

We know from Chapters 4 and 6 that, generally, mles are asymptotically unbiased estimators of θ . Hence, one way to proceed is to find a sufficient statistic and then find the mle. Based on this, we can often obtain an unbiased estimator that is a function of the sufficient statistic. This process is illustrated in the following example.

Example 7.3.1. Let X_1, \dots, X_n be iid with pdf

$$f(x; \theta) = \begin{cases} \theta e^{-\theta x} & 0 < x < \infty, \theta > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

Suppose we want an MVUE of θ . The joint pdf (likelihood function) is

$$L(\theta; x_1, \dots, x_n) = \theta^n e^{-\theta \sum_{i=1}^n x_i}, \quad \text{for } x_i > 0, i = 1, \dots, n.$$

Hence, by the factorization theorem, the statistic $Y_1 = \sum_{i=1}^n X_i$ is sufficient. The log of the likelihood function is

$$l(\theta) = n \log \theta - \theta \sum_{i=1}^n x_i.$$

Taking the partial with respect to θ of $l(\theta)$ and setting it to 0 results in the mle of θ , which is given by

$$Y_2 = \frac{1}{\bar{X}}.$$

Note that $Y_2 = n/Y_1$ is a function of the sufficient statistic Y_1 . Also, since Y_2 is the mle of θ , it is asymptotically unbiased. Hence, as a first step, we shall determine its expectation. In this problem, X_i are iid $\Gamma(1, 1/\theta)$ random variables; hence, $Y_1 = \sum_{i=1}^n X_i$ is $\Gamma(n, 1/\theta)$. Therefore,

$$E(Y_2) = E\left[\frac{1}{\bar{X}}\right] = nE\left[\frac{1}{\sum_{i=1}^n X_i}\right] = n \int_0^\infty \frac{\theta^n}{\Gamma(n)} t^{-1} t^{n-1} e^{-\theta t} dt;$$

making the change of variable $z = \theta t$ and simplifying results in

$$E(Y_2) = E\left[\frac{1}{\bar{X}}\right] = \theta \frac{n}{(n-1)!} \Gamma(n-1) = \theta \frac{n}{n-1}.$$

Thus the statistic $[(n-1)Y_2]/n = (n-1)/\sum_{i=1}^n X_i$ is an MVUE of θ . ■

In the next two sections, we discover that, in most instances, if there is one function $\varphi(Y_1)$ that is unbiased, $\varphi(Y_1)$ is the only unbiased estimator based on the sufficient statistic Y_1 .

Remark 7.3.1. Since the unbiased estimator $\varphi(Y_1)$, where $\varphi(Y_1) = E(Y_2|y_1)$, has a variance smaller than that of the unbiased estimator Y_2 of θ , students sometimes reason as follows. Let the function $\Upsilon(y_3) = E[\varphi(Y_1)|Y_3 = y_3]$, where Y_3 is another statistic, which is not sufficient for θ . By the Rao–Blackwell theorem, we have $E[\Upsilon(Y_3)] = \theta$ and $\Upsilon(Y_3)$ has a smaller variance than does $\varphi(Y_1)$. Accordingly, $\Upsilon(Y_3)$ must be better than $\varphi(Y_1)$ as an unbiased estimator of θ . But this is *not* true, because Y_3 is not sufficient; thus, θ is present in the conditional distribution of Y_1 , given $Y_3 = y_3$, and the conditional mean $\Upsilon(y_3)$. So although indeed $E[\Upsilon(Y_3)] = \theta$, $\Upsilon(Y_3)$ is not even a statistic because it involves the unknown parameter θ and hence cannot be used as an estimate. ■

We illustrate this remark in the following example.

Example 7.3.2. Let X_1, X_2, X_3 be a random sample from an exponential distribution with mean $\theta > 0$, so that the joint pdf is

$$\left(\frac{1}{\theta}\right)^3 e^{-(x_1+x_2+x_3)/\theta}, \quad 0 < x_i < \infty,$$

$i = 1, 2, 3$, zero elsewhere. From the factorization theorem, we see that $Y_1 = X_1 + X_2 + X_3$ is a sufficient statistic for θ . Of course,

$$E(Y_1) = E(X_1 + X_2 + X_3) = 3\theta,$$

and thus $Y_1/3 = \bar{X}$ is a function of the sufficient statistic that is an unbiased estimator of θ .

In addition, let $Y_2 = X_2 + X_3$ and $Y_3 = X_3$. The one-to-one transformation defined by

$$x_1 = y_1 - y_2, \quad x_2 = y_2 - y_3, \quad x_3 = y_3$$

has Jacobian equal to 1 and the joint pdf of Y_1, Y_2, Y_3 is

$$g(y_1, y_2, y_3; \theta) = \left(\frac{1}{\theta}\right)^3 e^{-y_1/\theta}, \quad 0 < y_3 < y_2 < y_1 < \infty,$$

zero elsewhere. The marginal pdf of Y_1 and Y_3 is found by integrating out y_2 to obtain

$$g_{13}(y_1, y_3; \theta) = \left(\frac{1}{\theta}\right)^3 (y_1 - y_3) e^{-y_1/\theta}, \quad 0 < y_3 < y_1 < \infty,$$

zero elsewhere. The pdf of Y_3 alone is

$$g_3(y_3; \theta) = \frac{1}{\theta} e^{-y_3/\theta}, \quad 0 < y_3 < \infty,$$

zero elsewhere, since $Y_3 = X_3$ is an observation of a random sample from this exponential distribution.

Accordingly, the conditional pdf of Y_1 , given $Y_3 = y_3$, is

$$\begin{aligned} g_{1|3}(y_1|y_3) &= \frac{g_{13}(y_1, y_3; \theta)}{g_3(y_3; \theta)} \\ &= \left(\frac{1}{\theta}\right)^2 (y_1 - y_3) e^{-(y_1-y_3)/\theta}, \quad 0 < y_3 < y_1 < \infty, \end{aligned}$$

zero elsewhere. Thus

$$\begin{aligned} E\left(\frac{Y_1}{3} \middle| y_3\right) &= E\left(\frac{Y_1 - Y_3}{3} \middle| y_3\right) + E\left(\frac{Y_3}{3} \middle| y_3\right) \\ &= \left(\frac{1}{3}\right) \int_{y_3}^{\infty} \left(\frac{1}{\theta}\right)^2 (y_1 - y_3)^2 e^{-(y_1-y_3)/\theta} dy_1 + \frac{y_3}{3} \\ &= \left(\frac{1}{3}\right) \frac{\Gamma(3)\theta^3}{\theta^2} + \frac{y_3}{3} = \frac{2\theta}{3} + \frac{y_3}{3} = \Upsilon(y_3). \end{aligned}$$

Of course, $E[\Upsilon(Y_3)] = \theta$ and $\text{var}[\Upsilon(Y_3)] \leq \text{var}(Y_1/3)$, but $\Upsilon(Y_3)$ is not a statistic, as it involves θ and cannot be used as an estimator of θ . This illustrates the preceding remark. ■

EXERCISES

7.3.1. In each of Exercises 7.2.1–7.2.4, show that the mle of θ is a function of the sufficient statistic for θ .

7.3.2. Let $Y_1 < Y_2 < Y_3 < Y_4 < Y_5$ be the order statistics of a random sample of size 5 from the uniform distribution having pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, $0 < \theta < \infty$, zero elsewhere. Show that $2Y_3$ is an unbiased estimator of θ . Determine the joint pdf of Y_3 and the sufficient statistic Y_5 for θ . Find the conditional expectation $E(2Y_3|y_5) = \varphi(y_5)$. Compare the variances of $2Y_3$ and $\varphi(Y_5)$.

7.3.3. If X_1, X_2 is a random sample of size 2 from a distribution having pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, $0 < \theta < \infty$, zero elsewhere, find the joint pdf of the sufficient statistic $Y_1 = X_1 + X_2$ for θ and $Y_2 = X_2$. Show that Y_2 is an unbiased estimator of θ with variance θ^2 . Find $E(Y_2|y_1) = \varphi(y_1)$ and the variance of $\varphi(Y_1)$.

7.3.4. Let $f(x, y) = (2/\theta^2)e^{-(x+y)/\theta}$, $0 < x < y < \infty$, zero elsewhere, be the joint pdf of the random variables X and Y .

- (a) Show that the mean and the variance of Y are, respectively, $3\theta/2$ and $5\theta^2/4$.
- (b) Show that $E(Y|x) = x + \theta$. In accordance with the theory, the expected value of $X + \theta$ is that of Y , namely, $3\theta/2$, and the variance of $X + \theta$ is less than that of Y . Show that the variance of $X + \theta$ is in fact $\theta^2/4$.

7.3.5. In each of Exercises 7.2.1–7.2.3, compute the expected value of the given sufficient statistic and, in each case, determine an unbiased estimator of θ that is a function of that sufficient statistic alone.

7.3.6. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with mean θ . Find the conditional expectation $E(X_1 + 2X_2 + 3X_3 | \sum_1^n X_i)$.

7.4 Completeness and Uniqueness

Let X_1, X_2, \dots, X_n be a random sample from the Poisson distribution that has pmf

$$f(x; \theta) = \begin{cases} \frac{\theta^x e^{-\theta}}{x!} & x = 0, 1, 2, \dots; \quad \theta > 0 \\ 0 & \text{elsewhere.} \end{cases}$$

From Exercise 7.2.2, we know that $Y_1 = \sum_{i=1}^n X_i$ is a sufficient statistic for θ and its pmf is

$$g_1(y_1; \theta) = \begin{cases} \frac{(n\theta)^{y_1} e^{-n\theta}}{y_1!} & y_1 = 0, 1, 2, \dots \\ 0 & \text{elsewhere.} \end{cases}$$

Let us consider the family $\{g_1(y_1; \theta) : \theta > 0\}$ of probability mass functions. Suppose that the function $u(Y_1)$ of Y_1 is such that $E[u(Y_1)] = 0$ for every $\theta > 0$. We shall show that this requires $u(y_1)$ to be zero at every point $y_1 = 0, 1, 2, \dots$. That is, $E[u(Y_1)] = 0$ for $\theta > 0$ requires

$$0 = u(0) = u(1) = u(2) = u(3) = \dots .$$

We have for all $\theta > 0$ that

$$\begin{aligned} 0 = E[u(Y_1)] &= \sum_{y_1=0}^{\infty} u(y_1) \frac{(n\theta)^{y_1} e^{-n\theta}}{y_1!} \\ &= e^{-n\theta} \left[u(0) + u(1) \frac{n\theta}{1!} + u(2) \frac{(n\theta)^2}{2!} + \dots \right]. \end{aligned}$$

Since $e^{-n\theta}$ does not equal zero, we have shown that

$$0 = u(0) + [nu(1)]\theta + \left[\frac{n^2 u(2)}{2} \right] \theta^2 + \dots .$$

However, if such an infinite (power) series converges to zero for all $\theta > 0$, then each of the coefficients must equal zero. That is,

$$u(0) = 0, \quad nu(1) = 0, \quad \frac{n^2 u(2)}{2} = 0, \dots ,$$

and thus $0 = u(0) = u(1) = u(2) = \dots$, as we wanted to show. Of course, the condition $E[u(Y_1)] = 0$ for all $\theta > 0$ does not place any restriction on $u(y_1)$ when y_1 is not a nonnegative integer. So we see that, in this illustration, $E[u(Y_1)] = 0$ for all $\theta > 0$ requires that $u(y_1)$ equals zero except on a set of points that has probability zero for each pmf $g_1(y_1; \theta)$, $0 < \theta$. From the following definition we observe that the family $\{g_1(y_1; \theta) : 0 < \theta\}$ is complete.

Definition 7.4.1. Let the random variable Z of either the continuous type or the discrete type have a pdf or pmf that is one member of the family $\{h(z; \theta) : \theta \in \Omega\}$. If the condition $E[u(Z)] = 0$, for every $\theta \in \Omega$, requires that $u(z)$ be zero except on a set of points that has probability zero for each $h(z; \theta)$, $\theta \in \Omega$, then the family $\{h(z; \theta) : \theta \in \Omega\}$ is called a **complete family** of probability density or mass functions.

Remark 7.4.1. In Section 1.8, it was noted that the existence of $E[u(X)]$ implies that the integral (or sum) converges absolutely. This absolute convergence was tacitly assumed in our definition of completeness and it is needed to prove that certain families of probability density functions are complete. ■

In order to show that certain families of probability density functions of the continuous type are complete, we must appeal to the same type of theorem in analysis that we used when we claimed that the moment generating function uniquely determines a distribution. This is illustrated in the next example.

Example 7.4.1. Consider the family of pdfs $\{h(z; \theta) : 0 < \theta < \infty\}$. Suppose Z has a pdf in this family given by

$$h(z; \theta) = \begin{cases} \frac{1}{\theta} e^{-z/\theta} & 0 < z < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Let us say that $E[u(Z)] = 0$ for every $\theta > 0$. That is,

$$\frac{1}{\theta} \int_0^\infty u(z) e^{-z/\theta} dz = 0, \quad \theta > 0.$$

Readers acquainted with the theory of transformations recognize the integral in the left-hand member as being essentially the Laplace transform of $u(z)$. In that theory we learn that the only function $u(z)$ transforming to a function of θ that is identically equal to zero is $u(z) = 0$, except (in our terminology) on a set of points that has probability zero for each $h(z; \theta)$, $\theta > 0$. That is, the family $\{h(z; \theta) : 0 < \theta < \infty\}$ is complete. ■

Let the parameter θ in the pdf or pmf $f(x; \theta)$, $\theta \in \Omega$, have a sufficient statistic $Y_1 = u_1(X_1, X_2, \dots, X_n)$, where X_1, X_2, \dots, X_n is a random sample from this distribution. Let the pdf or pmf of Y_1 be $f_{Y_1}(y_1; \theta)$, $\theta \in \Omega$. It has been seen that if there is any unbiased estimator Y_2 (not a function of Y_1 alone) of θ , then there is at least one function of Y_1 that is an unbiased estimator of θ , and our search for a best estimator of θ may be restricted to functions of Y_1 . Suppose it has been verified that a certain function $\varphi(Y_1)$, not a function of θ , is such that $E[\varphi(Y_1)] = \theta$ for all values of θ , $\theta \in \Omega$. Let $\psi(Y_1)$ be another function of the sufficient statistic Y_1 alone, so that we also have $E[\psi(Y_1)] = \theta$ for all values of θ , $\theta \in \Omega$. Hence

$$E[\varphi(Y_1) - \psi(Y_1)] = 0, \quad \theta \in \Omega.$$

If the family $\{f_{Y_1}(y_1; \theta) : \theta \in \Omega\}$ is complete, the function of $\varphi(y_1) - \psi(y_1) = 0$, except on a set of points that has probability zero. That is, for every other unbiased estimator $\psi(Y_1)$ of θ , we have

$$\varphi(y_1) = \psi(y_1)$$

except possibly at certain special points. Thus, in this sense [namely $\varphi(y_1) = \psi(y_1)$, except on a set of points with probability zero], $\varphi(Y_1)$ is the unique function of Y_1 , which is an unbiased estimator of θ . In accordance with the Rao–Blackwell theorem, $\varphi(Y_1)$ has a smaller variance than every other unbiased estimator of θ . That is, the statistic $\varphi(Y_1)$ is the MVUE of θ . This fact is stated in the following theorem of Lehmann and Scheffé.

Theorem 7.4.1 (Lehmann and Scheffé). *Let X_1, X_2, \dots, X_n , n a fixed positive integer, denote a random sample from a distribution that has pdf or pmf $f(x; \theta)$, $\theta \in \Omega$, let $Y_1 = u_1(X_1, X_2, \dots, X_n)$ be a sufficient statistic for θ , and let the family $\{f_{Y_1}(y_1; \theta) : \theta \in \Omega\}$ be complete. If there is a function of Y_1 that is an unbiased estimator of θ , then this function of Y_1 is the unique MVUE of θ . Here “unique” is used in the sense described in the preceding paragraph.*

The statement that Y_1 is a sufficient statistic for a parameter θ , $\theta \in \Omega$, and that the family $\{f_{Y_1}(y_1; \theta) : \theta \in \Omega\}$ of probability density functions is complete is lengthy and somewhat awkward. We shall adopt the less descriptive, but more convenient, terminology that Y_1 is a **complete sufficient statistic** for θ . In the next section, we study a fairly large class of probability density functions for which a complete sufficient statistic Y_1 for θ can be determined by inspection.

Example 7.4.2 (Uniform Distribution). Let X_1, X_2, \dots, X_n be a random sample from the uniform distribution with pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, $\theta > 0$, and zero elsewhere. As Exercise 7.2.3 shows, $Y_n = \max\{X_1, X_2, \dots, X_n\}$ is a sufficient statistic for θ . It is easy to show that the pdf of Y_n is

$$g(y_n; \theta) = \begin{cases} \frac{ny_n^{n-1}}{\theta^n} & 0 < y_n < \theta \\ 0 & \text{elsewhere.} \end{cases} \quad (7.4.1)$$

To show that Y_n is complete, suppose for any function $u(t)$ and any θ that $E[u(Y_n)] = 0$; i.e.,

$$0 = \int_0^\theta u(t) \frac{nt^{n-1}}{\theta^n} dt.$$

Since $\theta > 0$, this equation is equivalent to

$$0 = \int_0^\theta u(t) t^{n-1} dt.$$

Taking partial derivatives of both sides with respect to θ and using the Fundamental Theorem of Calculus, we have

$$0 = u(\theta) \theta^{n-1}.$$

Since $\theta > 0$, $u(\theta) = 0$, for all $\theta > 0$. Thus Y_n is a complete and sufficient statistic for θ . It is easy to show that

$$E(Y_n) = \int_0^\theta y \frac{ny^{n-1}}{\theta^n} dy = \frac{n}{n+1} \theta.$$

Therefore, the MVUE of θ is $((n+1)/n)Y_n$. ■

EXERCISES

7.4.1. If $az^2 + bz + c = 0$ for more than two values of z , then $a = b = c = 0$. Use this result to show that the family $\{b(2, \theta) : 0 < \theta < 1\}$ is complete.

7.4.2. Show that each of the following families is not complete by finding at least one nonzero function $u(x)$ such that $E[u(X)] = 0$, for all $\theta > 0$.

(a)

$$f(x; \theta) = \begin{cases} \frac{1}{2\theta} & -\theta < x < \theta, \quad \text{where } 0 < \theta < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

(b) $N(0, \theta)$, where $0 < \theta < \infty$.

7.4.3. Let X_1, X_2, \dots, X_n represent a random sample from the discrete distribution having the pmf

$$f(x; \theta) = \begin{cases} \theta^x (1 - \theta)^{1-x} & x = 0, 1, \quad 0 < \theta < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

Show that $Y_1 = \sum_1^n X_i$ is a complete sufficient statistic for θ . Find the unique function of Y_1 that is the MVUE of θ .

Hint: Display $E[u(Y_1)] = 0$, show that the constant term $u(0)$ is equal to zero, divide both members of the equation by $\theta \neq 0$, and repeat the argument.

7.4.4. Consider the family of probability density functions $\{h(z; \theta) : \theta \in \Omega\}$, where $h(z; \theta) = 1/\theta$, $0 < z < \theta$, zero elsewhere.

(a) Show that the family is complete provided that $\Omega = \{\theta : 0 < \theta < \infty\}$.

Hint: For convenience, assume that $u(z)$ is continuous and note that the derivative of $E[u(Z)]$ with respect to θ is equal to zero also.

(b) Show that this family is not complete if $\Omega = \{\theta : 1 < \theta < \infty\}$.

Hint: Concentrate on the interval $0 < z < 1$ and find a nonzero function $u(z)$ on that interval such that $E[u(Z)] = 0$ for all $\theta > 1$.

7.4.5. Show that the first order statistic Y_1 of a random sample of size n from the distribution having pdf $f(x; \theta) = e^{-(x-\theta)}$, $\theta < x < \infty$, $-\infty < \theta < \infty$, zero elsewhere, is a complete sufficient statistic for θ . Find the unique function of this statistic which is the MVUE of θ .

7.4.6. Let a random sample of size n be taken from a distribution of the discrete type with pmf $f(x; \theta) = 1/\theta$, $x = 1, 2, \dots, \theta$, zero elsewhere, where θ is an unknown positive integer.

(a) Show that the largest observation, say Y , of the sample is a complete sufficient statistic for θ .

(b) Prove that

$$[Y^{n+1} - (Y - 1)^{n+1}] / [Y^n - (Y - 1)^n]$$

is the unique MVUE of θ .

7.4.7. Let X have the pdf $f_X(x; \theta) = 1/(2\theta)$, for $-\theta < x < \theta$, zero elsewhere, where $\theta > 0$.

(a) Is the statistic $Y = |X|$ a sufficient statistic for θ ? Why?

(b) Let $f_Y(y; \theta)$ be the pdf of Y . Is the family $\{f_Y(y; \theta) : \theta > 0\}$ complete? Why?

7.4.8. Let X have the pmf $p(x; \theta) = \frac{1}{2} \binom{n}{|x|} \theta^{|x|} (1 - \theta)^{n-|x|}$, for $x = \pm 1, \pm 2, \dots, \pm n$, $p(0, \theta) = (1 - \theta)^n$, and zero elsewhere, where $0 < \theta < 1$.

(a) Show that this family $\{p(x; \theta) : 0 < \theta < 1\}$ is not complete.

(b) Let $Y = |X|$. Show that Y is a complete and sufficient statistic for θ .

7.4.9. Let X_1, \dots, X_n be iid with pdf $f(x; \theta) = 1/(3\theta)$, $-\theta < x < 2\theta$, zero elsewhere, where $\theta > 0$.

(a) Find the mle $\hat{\theta}$ of θ .

(b) Is $\hat{\theta}$ a sufficient statistic for θ ? Why?

(c) Is $(n+1)\hat{\theta}/n$ the unique MVUE of θ ? Why?

7.4.10. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from a distribution with pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere. By Example 7.4.2, the statistic Y_n is a complete sufficient statistic for θ and it has pdf

$$g(y_n; \theta) = \frac{ny_n^{n-1}}{\theta^n}, \quad 0 < y_n < \theta,$$

and zero elsewhere.

(a) Find the distribution function $H_n(z; \theta)$ of $Z = n(\theta - Y_n)$.

(b) Find the $\lim_{n \rightarrow \infty} H_n(z; \theta)$ and thus the limiting distribution of Z .

7.5 The Exponential Class of Distributions

In this section we discuss an important class of distributions, called the *exponential class*. As we show, this class possesses complete and sufficient statistics which are readily determined from the distribution.

Consider a family $\{f(x; \theta) : \theta \in \Omega\}$ of probability density or mass functions, where Ω is the interval set $\Omega = \{\theta : \gamma < \theta < \delta\}$, where γ and δ are known constants (they may be $\pm\infty$), and where

$$f(x; \theta) = \begin{cases} \exp[p(\theta)K(x) + H(x) + q(\theta)] & x \in \mathcal{S} \\ 0 & \text{elsewhere,} \end{cases} \quad (7.5.1)$$

where \mathcal{S} is the support of X . In this section we are concerned with a particular class of the family called the regular exponential class.

Definition 7.5.1 (Regular Exponential Class). A pdf of the form (7.5.1) is said to be a member of the **regular exponential class** of probability density or mass functions if

1. \mathcal{S} , the support of X , does not depend upon θ
2. $p(\theta)$ is a nontrivial continuous function of $\theta \in \Omega$
3. Finally,
 - (a) if X is a continuous random variable, then each of $K'(x) \not\equiv 0$ and $H(x)$ is a continuous function of $x \in \mathcal{S}$,

(b) if X is a discrete random variable, then $K(x)$ is a nontrivial function of $x \in \mathcal{S}$.

For example, each member of the family $\{f(x; \theta) : 0 < \theta < \infty\}$, where $f(x; \theta)$ is $N(0, \theta)$, represents a regular case of the exponential class of the continuous type because

$$\begin{aligned} f(x; \theta) &= \frac{1}{\sqrt{2\pi\theta}} e^{-x^2/2\theta} \\ &= \exp\left(-\frac{1}{2\theta}x^2 - \log\sqrt{2\pi\theta}\right), \quad -\infty < x < \infty. \end{aligned}$$

On the other hand, consider the uniform density function given by

$$f(x; \theta) = \begin{cases} \exp\{-\log\theta\} & x \in (0, \theta) \\ 0 & \text{elsewhere.} \end{cases}$$

This can be written in the form (7.5.1), but the support is the interval $(0, \theta)$, which depends on θ . Hence the uniform family is not a regular exponential family.

Let X_1, X_2, \dots, X_n denote a random sample from a distribution that represents a regular case of the exponential class. The joint pdf or pmf of X_1, X_2, \dots, X_n is

$$\exp\left[p(\theta) \sum_1^n K(x_i) + \sum_1^n H(x_i) + nq(\theta)\right]$$

for $x_i \in \mathcal{S}$, $i = 1, 2, \dots, n$ and zero elsewhere. At points in the \mathcal{S} of X , this joint pdf or pmf may be written as the product of the two nonnegative functions

$$\exp\left[p(\theta) \sum_1^n K(x_i) + nq(\theta)\right] \exp\left[\sum_1^n H(x_i)\right].$$

In accordance with the factorization theorem, Theorem 7.2.1, $Y_1 = \sum_1^n K(X_i)$ is a sufficient statistic for the parameter θ .

Besides the fact that Y_1 is a sufficient statistic, we can obtain the general form of the distribution of Y_1 and its mean and variance. We summarize these results in a theorem. The details of the proof are given in Exercises 7.5.5 and 7.5.8. Exercise 7.5.6 obtains the mgf of Y_1 in the case that $p(\theta) = \theta$.

Theorem 7.5.1. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that represents a regular case of the exponential class, with pdf or pmf given by (7.5.1). Consider the statistic $Y_1 = \sum_{i=1}^n K(X_i)$. Then

1. The pdf or pmf of Y_1 has the form

$$f_{Y_1}(y_1; \theta) = R(y_1) \exp[p(\theta)y_1 + nq(\theta)], \quad (7.5.2)$$

for $y_1 \in \mathcal{S}_{Y_1}$ and some function $R(y_1)$. Neither \mathcal{S}_{Y_1} nor $R(y_1)$ depends on θ .

2. $E(Y_1) = -n \frac{q'(\theta)}{p'(\theta)}$.

$$3. \text{Var}(Y_1) = n \frac{1}{p'(\theta)^3} \{p''(\theta)q'(\theta) - q''(\theta)p'(\theta)\}.$$

Example 7.5.1. Let X have a Poisson distribution with parameter $\theta \in (0, \infty)$. Then the support of X is the set $\mathcal{S} = \{0, 1, 2, \dots\}$, which does not depend on θ . Further, the pmf of X on its support is

$$f(x, \theta) = e^{-\theta} \frac{\theta^x}{x!} = \exp\{(\log \theta)x + \log(1/x!) + (-\theta)\}.$$

Hence the Poisson distribution is a member of the regular exponential class, with $p(\theta) = \log(\theta)$, $q(\theta) = -\theta$, and $K(x) = x$. Therefore, if X_1, X_2, \dots, X_n denotes a random sample on X , then the statistic $Y_1 = \sum_{i=1}^n X_i$ is sufficient. But since $p'(\theta) = 1/\theta$ and $q'(\theta) = -1$, Theorem 7.5.1 verifies that the mean of Y_1 is $n\theta$. It is easy to verify that the variance of Y_1 is $n\theta$ also. Finally, we can show that the function $R(y_1)$ in Theorem 7.5.1 is given by $R(y_1) = n^{y_1} (1/y_1!)$. ■

For the regular case of the exponential class, we have shown that the statistic $Y_1 = \sum_1^n K(X_i)$ is sufficient for θ . We now use the form of the pdf of Y_1 given in Theorem 7.5.1 to establish the completeness of Y_1 .

Theorem 7.5.2. *Let $f(x; \theta)$, $\gamma < \theta < \delta$, be a pdf or pmf of a random variable X whose distribution is a regular case of the exponential class. Then if X_1, X_2, \dots, X_n (where n is a fixed positive integer) is a random sample from the distribution of X , the statistic $Y_1 = \sum_1^n K(X_i)$ is a sufficient statistic for θ and the family $\{f_{Y_1}(y_1; \theta) : \gamma < \theta < \delta\}$ of probability density functions of Y_1 is complete. That is, Y_1 is a complete sufficient statistic for θ .*

Proof: We have shown above that Y_1 is sufficient. For completeness, suppose that $E[u(Y_1)] = 0$. Expression (7.5.2) of Theorem 7.5.1 gives the pdf of Y_1 . Hence we have the equation

$$\int_{\mathcal{S}_{Y_1}} u(y_1) R(y_1) \exp\{p(\theta)y_1 + nq(\theta)\} dy_1 = 0$$

or equivalently since $\exp\{nq(\theta)\} \neq 0$,

$$\int_{\mathcal{S}_{Y_1}} u(y_1) R(y_1) \exp\{p(\theta)y_1\} dy_1 = 0$$

for all θ . However, $p(\theta)$ is a nontrivial continuous function of θ , and thus this integral is essentially a type of Laplace transform of $u(y_1)R(y_1)$. The only function of y_1 transforming to the 0 function is the zero function (except for a set of points with probability zero in our context). That is,

$$u(y_1)R(y_1) \equiv 0.$$

However, $R(y_1) \neq 0$ for all $y_1 \in \mathcal{S}_{Y_1}$ because it is a factor in the pdf of Y_1 . Hence $u(y_1) \equiv 0$ (except for a set of points with probability zero). Therefore, Y_1 is a complete sufficient statistic for θ . ■

This theorem has useful implications. In a regular case of form (7.5.1), we can see by inspection that the sufficient statistic is $Y_1 = \sum_1^n K(X_i)$. If we can see how to form a function of Y_1 , say $\varphi(Y_1)$, so that $E[\varphi(Y_1)] = \theta$, then the statistic $\varphi(Y_1)$ is unique and is the MVUE of θ .

Example 7.5.2. Let X_1, X_2, \dots, X_n denote a random sample from a normal distribution that has pdf

$$f(x; \theta) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{(x-\theta)^2}{2\sigma^2}\right], \quad -\infty < x < \infty, \quad -\infty < \theta < \infty,$$

or

$$f(x; \theta) = \exp\left(\frac{\theta}{\sigma^2}x - \frac{x^2}{2\sigma^2} - \log\sqrt{2\pi\sigma^2} - \frac{\theta^2}{2\sigma^2}\right).$$

Here σ^2 is any fixed positive number. This is a regular case of the exponential class with

$$\begin{aligned} p(\theta) &= \frac{\theta}{\sigma^2}, \quad K(x) = x, \\ H(x) &= -\frac{x^2}{2\sigma^2} - \log\sqrt{2\pi\sigma^2}, \quad q(\theta) = -\frac{\theta^2}{2\sigma^2}. \end{aligned}$$

Accordingly, $Y_1 = X_1 + X_2 + \dots + X_n = n\bar{X}$ is a complete sufficient statistic for the mean θ of a normal distribution for every fixed value of the variance σ^2 . Since $E(Y_1) = n\theta$, then $\varphi(Y_1) = Y_1/n = \bar{X}$ is the only function of Y_1 that is an unbiased estimator of θ ; and being a function of the sufficient statistic Y_1 , it has a minimum variance. That is, \bar{X} is the unique MVUE of θ . Incidentally, since Y_1 is a one-to-one function of \bar{X} , \bar{X} itself is also a complete sufficient statistic for θ . ■

Example 7.5.3 (Example 7.5.1, Continued). Reconsider the discussion concerning the Poisson distribution with parameter θ found in Example 7.5.1. Based on this discussion, the statistic $Y_1 = \sum_{i=1}^n X_i$ was sufficient. It follows from Theorem 7.5.2 that its family of distributions is complete. Since $E(Y_1) = n\theta$, it follows that $\bar{X} = n^{-1}Y_1$ is the unique MVUE of θ . ■

EXERCISES

7.5.1. Write the pdf

$$f(x; \theta) = \frac{1}{6\theta^4} x^3 e^{-x/\theta}, \quad 0 < x < \infty, \quad 0 < \theta < \infty,$$

zero elsewhere, in the exponential form. If X_1, X_2, \dots, X_n is a random sample from this distribution, find a complete sufficient statistic Y_1 for θ and the unique function $\varphi(Y_1)$ of this statistic that is the MVUE of θ . Is $\varphi(Y_1)$ itself a complete sufficient statistic?

7.5.2. Let X_1, X_2, \dots, X_n denote a random sample of size $n > 1$ from a distribution with pdf $f(x; \theta) = \theta e^{-\theta x}$, $0 < x < \infty$, zero elsewhere, and $\theta > 0$. Then $Y = \sum_1^n X_i$ is a sufficient statistic for θ . Prove that $(n-1)/Y$ is the MVUE of θ .

7.5.3. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution with pdf $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, zero elsewhere, and $\theta > 0$.

- (a) Show that the *geometric mean* $(X_1 X_2 \cdots X_n)^{1/n}$ of the sample is a complete sufficient statistic for θ .
- (b) Find the maximum likelihood estimator of θ , and observe that it is a function of this geometric mean.

7.5.4. Let \bar{X} denote the mean of the random sample X_1, X_2, \dots, X_n from a gamma-type distribution with parameters $\alpha > 0$ and $\beta = \theta > 0$. Compute $E[X_1|\bar{x}]$.

Hint: Can you find directly a function $\psi(\bar{X})$ of \bar{X} such that $E[\psi(\bar{X})] = \theta$? Is $E(X_1|\bar{x}) = \psi(\bar{x})$? Why?

7.5.5. Let X be a random variable with the pdf of a regular case of the exponential class, given by $f(x; \theta) = \exp[\theta K(x) + H(x) + q(\theta)]$, $a < x < b$, $\gamma < \theta < \delta$. Show that $E[K(X)] = -q'(\theta)/p'(\theta)$, provided these derivatives exist, by differentiating both members of the equality

$$\int_a^b \exp[p(\theta)K(x) + H(x) + q(\theta)] dx = 1$$

with respect to θ . By a second differentiation, find the variance of $K(X)$.

7.5.6. Given that $f(x; \theta) = \exp[\theta K(x) + H(x) + q(\theta)]$, $a < x < b$, $\gamma < \theta < \delta$, represents a regular case of the exponential class, show that the moment-generating function $M(t)$ of $Y = K(X)$ is $M(t) = \exp[q(\theta) - q(\theta + t)]$, $\gamma < \theta + t < \delta$.

7.5.7. In the preceding exercise, given that $E(Y) = E[K(X)] = \theta$, prove that Y is $N(\theta, 1)$.

Hint: Consider $M'(0) = \theta$ and solve the resulting differential equation.

7.5.8. If X_1, X_2, \dots, X_n is a random sample from a distribution that has a pdf which is a regular case of the exponential class, show that the pdf of $Y_1 = \sum_1^n K(X_i)$ is of the form $f_{Y_1}(y_1; \theta) = R(y_1) \exp[p(\theta)y_1 + nq(\theta)]$.

Hint: Let $Y_2 = X_2, \dots, Y_n = X_n$ be $n - 1$ auxiliary random variables. Find the joint pdf of Y_1, Y_2, \dots, Y_n and then the marginal pdf of Y_1 .

7.5.9. Let Y denote the median and let \bar{X} denote the mean of a random sample of size $n = 2k + 1$ from a distribution that is $N(\mu, \sigma^2)$. Compute $E(Y|\bar{X} = \bar{x})$.

Hint: See Exercise 7.5.4.

7.5.10. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pdf $f(x; \theta) = \theta^2 x e^{-\theta x}$, $0 < x < \infty$, where $\theta > 0$.

- (a) Argue that $Y = \sum_1^n X_i$ is a complete sufficient statistic for θ .
- (b) Compute $E(1/Y)$ and find the function of Y that is the unique MVUE of θ .

7.5.11. Let X_1, X_2, \dots, X_n , $n > 2$, be a random sample from the binomial distribution $b(1, \theta)$.

- (a) Show that $Y_1 = X_1 + X_2 + \cdots + X_n$ is a complete sufficient statistic for θ .
- (b) Find the function $\varphi(Y_1)$ that is the MVUE of θ .
- (c) Let $Y_2 = (X_1 + X_2)/2$ and compute $E(Y_2)$.
- (d) Determine $E(Y_2|Y_1 = y_1)$.

7.5.12. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pmf $p(x; \theta) = \theta^x(1 - \theta)^{1-x}$, $x = 0, 1, 2, \dots$, zero elsewhere, where $0 \leq \theta \leq 1$.

- (a) Find the mle, $\hat{\theta}$, of θ .
- (b) Show that $\sum_1^n X_i$ is a complete sufficient statistic for θ .
- (c) Determine the MVUE of θ .

7.6 Functions of a Parameter

Up to this point we have sought an MVUE of a parameter θ . Not always, however, are we interested in θ but rather in a function of θ . There are several techniques we can use to find the MVUE. One is by inspection of the expected value of a sufficient statistic. This is how we found the MVUEs in Examples 7.5.2 and 7.5.3 of the last section. In this section and its exercises, we offer more examples of the inspection technique. The second technique is based on the conditional expectation of an unbiased estimate given a sufficient statistic. The third example illustrates this technique.

Recall that in Chapter 6 under regularity conditions, we obtained the asymptotic distribution theory for maximum likelihood estimators (mles). This allows certain asymptotic inferences (confidence intervals and tests) for these estimators. Such a straightforward theory is not available for MVUEs. As Theorem 7.3.2 shows, though, sometimes we can determine the relationship between the mle and the MVUE. In these situations, we can often obtain the asymptotic distribution for the MVUE based on the asymptotic distribution of the mle. Also, as we discuss in Section 7.6.1, we can usually make use of the bootstrap to obtain standard errors for MVUE estimates. We illustrate this for some of the following examples.

Example 7.6.1. Let X_1, X_2, \dots, X_n denote the observations of a random sample of size $n > 1$ from a distribution that is $b(1, \theta)$, $0 < \theta < 1$. We know that if $Y = \sum_1^n X_i$, then Y/n is the unique minimum variance unbiased estimator of θ . Now suppose we want to estimate the variance of Y/n , which is $\theta(1 - \theta)/n$. Let $\delta = \theta(1 - \theta)$. Because Y is a sufficient statistic for θ , it is known that we can restrict our search to functions of Y . The maximum likelihood estimate of δ , which is given by $\tilde{\delta} = (Y/n)(1 - Y/n)$, is a function of the sufficient statistic and seems to be a reasonable starting point. The expectation of this statistic is given by

$$E[\tilde{\delta}] = E\left[\frac{Y}{n}\left(1 - \frac{Y}{n}\right)\right] = \frac{1}{n}E(Y) - \frac{1}{n^2}E(Y^2).$$

Now $E(Y) = n\theta$ and $E(Y^2) = n\theta(1 - \theta) + n^2\theta^2$. Hence

$$E\left[\frac{Y}{n}\left(1 - \frac{Y}{n}\right)\right] = (n-1)\frac{\theta(1-\theta)}{n}.$$

If we multiply both members of this equation by $n/(n-1)$, we find that the statistic $\hat{\delta} = (n/(n-1))(Y/n)(1 - Y/n) = (n/(n-1))\tilde{\delta}$ is the unique MVUE of δ . Hence the MVUE of δ/n , the variance of Y/n , is $\hat{\delta}/n$.

It is interesting to compare the mle $\tilde{\delta}$ with $\hat{\delta}$. Recall from Chapter 6 that the mle $\tilde{\delta}$ is a consistent estimate of δ and that $\sqrt{n}(\tilde{\delta} - \delta)$ is asymptotically normal. Because

$$\hat{\delta} - \tilde{\delta} = \tilde{\delta}\frac{1}{n-1} \xrightarrow{P} \delta \cdot 0 = 0,$$

it follows that $\hat{\delta}$ is also a consistent estimator of δ . Further,

$$\sqrt{n}(\hat{\delta} - \delta) - \sqrt{n}(\tilde{\delta} - \delta) = \frac{\sqrt{n}}{n-1}\tilde{\delta} \xrightarrow{P} 0. \quad (7.6.1)$$

Hence $\sqrt{n}(\hat{\delta} - \delta)$ has the same asymptotic distribution as $\sqrt{n}(\tilde{\delta} - \delta)$. Using the Δ -method, Theorem 5.2.9, we can obtain the asymptotic distribution of $\sqrt{n}(\hat{\delta} - \delta)$. Let $g(\theta) = \theta(1 - \theta)$. Then $g'(\theta) = 1 - 2\theta$. Hence, by Theorem 5.2.9 and (7.6.1), the asymptotic distribution of $\sqrt{n}(\hat{\delta} - \delta)$ is given by

$$\sqrt{n}(\hat{\delta} - \delta) \xrightarrow{D} N(0, \theta(1 - \theta)(1 - 2\theta)^2),$$

provided $\theta \neq 1/2$; see Exercise 7.6.12 for the case $\theta = 1/2$. ■

In the next example, we consider the uniform $(0, \theta)$ distribution and obtain the MVUE for all differentiable functions of θ . This example was sent to us by Professor Bradford Crain of Portland State University.

Example 7.6.2. Suppose X_1, X_2, \dots, X_n are iid random variables with the common uniform $(0, \theta)$ distribution. Let $Y_n = \max\{X_1, X_2, \dots, X_n\}$. In Example 7.4.2, we showed that Y_n is a complete and sufficient statistic of θ and the pdf of Y_n is given by (7.4.1). Let $g(\theta)$ be any differentiable function of θ . Then the MVUE of $g(\theta)$ is the statistic $u(Y_n)$, which satisfies the equation

$$g(\theta) = \int_0^\theta u(y) \frac{ny^{n-1}}{\theta^n} dy, \quad \theta > 0,$$

or equivalently,

$$g(\theta)\theta^n = \int_0^\theta u(y)ny^{n-1} dy, \quad \theta > 0.$$

Differentiating both sides of this equation with respect to θ , we obtain

$$n\theta^{n-1}g(\theta) + \theta^n g'(\theta) = u(\theta)n\theta^{n-1}.$$

Solving for $u(\theta)$, we obtain

$$u(\theta) = g(\theta) + \frac{\theta g'(\theta)}{n}.$$

Therefore, the MVUE of $g(\theta)$ is

$$u(Y_n) = g(Y_n) + \frac{Y_n}{n}g'(Y_n). \quad (7.6.2)$$

For example, if $g(\theta) = \theta$, then

$$u(Y_n) = Y_n + \frac{Y_n}{n} = \frac{n+1}{n}Y_n,$$

which agrees with the result obtained in Example 7.4.2. Other examples are given in Exercise 7.6.5. ■

A somewhat different but also very important problem in point estimation is considered in the next example. In the example the distribution of a random variable X is described by a pdf $f(x; \theta)$ that depends upon $\theta \in \Omega$. The problem is to estimate the fractional part of the probability for this distribution, which is at, or to the left of, a fixed point c . Thus we seek an MVUE of $F(c; \theta)$, where $F(x; \theta)$ is the cdf of X .

Example 7.6.3. Let X_1, X_2, \dots, X_n be a random sample of size $n > 1$ from a distribution that is $N(\theta, 1)$. Suppose that we wish to find an MVUE of the function of θ defined by

$$P(X \leq c) = \int_{-\infty}^c \frac{1}{\sqrt{2\pi}} e^{-(x-\theta)^2/2} dx = \Phi(c - \theta),$$

where c is a fixed constant. There are many unbiased estimators of $\Phi(c - \theta)$. We first exhibit one of these, say $u(X_1)$, a function of X_1 alone. We shall then compute the conditional expectation, $E[u(X_1)|\bar{X} = \bar{x}] = \varphi(\bar{x})$, of this unbiased statistic, given the sufficient statistic \bar{X} , the mean of the sample. In accordance with the theorems of Rao–Blackwell and Lehmann–Scheffé, $\varphi(\bar{X})$ is the unique MVUE of $\Phi(c - \theta)$.

Consider the function $u(x_1)$, where

$$u(x_1) = \begin{cases} 1 & x_1 \leq c \\ 0 & x_1 > c. \end{cases}$$

The expected value of the random variable $u(X_1)$ is given by

$$E[u(X_1)] = 1 \cdot P[X_1 - \theta \leq c - \theta] = \Phi(c - \theta).$$

That is, $u(X_1)$ is an unbiased estimator of $\Phi(c - \theta)$.

We shall next discuss the joint distribution of X_1 and \bar{X} and the conditional distribution of X_1 , given $\bar{X} = \bar{x}$. This conditional distribution enables us to compute the conditional expectation $E[u(X_1)|\bar{X} = \bar{x}] = \varphi(\bar{x})$. In accordance with Exercise

7.6.8, the joint distribution of X_1 and \bar{X} is bivariate normal with mean vector (θ, θ) , variances $\sigma_1^2 = 1$ and $\sigma_2^2 = 1/n$, and correlation coefficient $\rho = 1/\sqrt{n}$. Thus the conditional pdf of X_1 , given $\bar{X} = \bar{x}$, is normal with linear conditional mean

$$\theta + \frac{\rho\sigma_1}{\sigma_2}(\bar{x} - \theta) = \bar{x}$$

and with variance

$$\sigma_1^2(1 - \rho^2) = \frac{n-1}{n}.$$

The conditional expectation of $u(X_1)$, given $\bar{X} = \bar{x}$, is then

$$\begin{aligned}\varphi(\bar{x}) &= \int_{-\infty}^{\infty} u(x_1) \sqrt{\frac{n}{n-1}} \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{n(x_1 - \bar{x})^2}{2(n-1)}\right] dx_1 \\ &= \int_{-\infty}^c \sqrt{\frac{n}{n-1}} \frac{1}{\sqrt{2\pi}} \exp\left[-\frac{n(x_1 - \bar{x})^2}{2(n-1)}\right] dx_1.\end{aligned}$$

The change of variable $z = \sqrt{n}(x_1 - \bar{x})/\sqrt{n-1}$ enables us to write this conditional expectation as

$$\varphi(\bar{x}) = \int_{-\infty}^{c'} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \Phi(c') = \Phi\left[\frac{\sqrt{n}(c - \bar{x})}{\sqrt{n-1}}\right],$$

where $c' = \sqrt{n}(c - \bar{x})/\sqrt{n-1}$. Thus the unique MVUE of $\Phi(c - \theta)$ is, for every fixed constant c , given by $\varphi(\bar{X}) = \Phi[\sqrt{n}(c - \bar{X})/\sqrt{n-1}]$.

In this example the mle of $\Phi(c - \theta)$ is $\Phi(c - \bar{X})$. These two estimators are close because $\sqrt{n/(n-1)} \rightarrow 1$, as $n \rightarrow \infty$. ■

Remark 7.6.1. We should like to draw the attention of the reader to a rather important fact. This has to do with the adoption of a *principle*, such as the principle of unbiasedness and minimum variance. A principle is not a theorem; and seldom does a principle yield satisfactory results in all cases. So far, this principle has provided quite satisfactory results. To see that this is not always the case, let X have a Poisson distribution with parameter θ , $0 < \theta < \infty$. We may look upon X as a random sample of size 1 from this distribution. Thus X is a complete sufficient statistic for θ . We seek the estimator of $e^{-2\theta}$ that is unbiased and has minimum variance. Consider $Y = (-1)^X$. We have

$$E(Y) = E[(-1)^X] = \sum_{x=0}^{\infty} \frac{(-\theta)^x e^{-\theta}}{x!} = e^{-2\theta}.$$

Accordingly, $(-1)^X$ is the MVUE of $e^{-2\theta}$. Here this estimator leaves much to be desired. We are endeavoring to elicit some information about the number $e^{-2\theta}$, where $0 < e^{-2\theta} < 1$; yet our point estimate is either -1 or $+1$, each of which is a very poor estimate of a number between 0 and 1. We do not wish to leave the reader with the impression that an MVUE is *bad*. That is not the case at all. We merely wish to point out that if one tries hard enough, one can find instances where such a statistic is *not good*. Incidentally, the maximum likelihood estimator of $e^{-2\theta}$ is, in the case where the sample size equals 1, e^{-2X} , which is probably a much better estimator in practice than is the unbiased estimator $(-1)^X$. ■

7.6.1 Bootstrap Standard Errors

Section 6.3 presented the asymptotic theory of maximum likelihood estimators (mles). In many cases, this theory also provides consistent estimators of the asymptotic standard deviation of mles. This allows a simple, but very useful, summary of the estimation process; i.e., $\hat{\theta} \pm \text{SE}(\hat{\theta})$ where $\hat{\theta}$ is the mle of θ and $\text{SE}(\hat{\theta})$ is the corresponding standard error. For example, these summaries can be used descriptively as labels on plots and tables as well as in the formation of asymptotic confidence intervals for inference. Section 4.9 presented percentile confidence intervals for θ based on the bootstrap. The bootstrap, though, can also be used to obtain standard errors for estimates including MVUE's.

Consider a random variable X with pdf $f(x; \theta)$, where $\theta \in \Omega$. Let X_1, \dots, X_n be a random sample on X . Let $\hat{\theta}$ be an estimator of θ based on the sample. Suppose x_1, \dots, x_n is a realization of the sample and let $\hat{\theta} = \hat{\theta}(x_1, \dots, x_n)$ be the corresponding estimate of θ . Recall in Section 4.9 that the bootstrap uses the empirical cdf \hat{F}_n of the realization. This is the discrete distribution which places mass $1/n$ at each point x_i . The bootstrap procedure samples, with replacement, from \hat{F}_n .

For the bootstrap procedure, we obtain B bootstrap samples. For $i = 1, \dots, B$, let the vector $\mathbf{x}_i^* = (x_{i,1}^*, \dots, x_{i,n}^*)'$ denote the i th bootstrap sample. Let $\hat{\theta}_i^* = \hat{\theta}(\mathbf{x}_i^*)$ denote the estimate of θ based on the i th sample. We then have the bootstrap estimates $\hat{\theta}_1^*, \dots, \hat{\theta}_B^*$, which we used in Section 4.9 to obtain the bootstrap percentile confidence interval for θ . Suppose instead we consider the standard deviation of these bootstrap estimates; that is,

$$\text{SE}_B = \left[\frac{1}{B-1} \sum_{i=1}^B (\hat{\theta}_1^* - \bar{\hat{\theta}}^*)^2 \right]^{1/2}, \quad (7.6.3)$$

where $\bar{\hat{\theta}}^* = (1/B) \sum_{i=1}^B \hat{\theta}_1^*$. This is the bootstrap estimate of the standard error of $\hat{\theta}$.

Example 7.6.4. For this example, we consider a data set drawn from a normal distribution, $N(\theta, \sigma^2)$. In this case the MVUE of θ is the sample mean \bar{X} and its usual standard error is s/\sqrt{n} , where s is the sample standard deviation. The rounded data¹ are:

```
27.5 50.9 71.1 43.1 40.4 44.8 36.6 53.5 65.2 47.7
75.7 55.4 61.1 39.8 33.4 57.6 47.9 60.7 27.8 65.2
```

Assuming the data are in the R vector \mathbf{x} , the mean and standard error are computed as

```
mean(x); 50.27; sd(x)/sqrt(n); 3.094461
```

The R function `bootse1.R` runs the bootstrap for standard errors as described above. Using 3,000 bootstraps, our run of this function estimated the standard error by 3.050878. Thus, the estimate and the bootstrap standard error are summarized as 50.27 ± 3.05 . ■

¹The data are in the file `sect76data.rda`. The true mean and sd are: 50 and 15.

The bootstrap process described above is often called the **nonparametric bootstrap** because it makes no assumptions about the pdf $f(x; \theta)$. In this chapter, though, strong assumptions are made about the model. For instance, in the last example, we assume that the pdf is normal. What if we make use of this information in the bootstrap? This is called the **parametric bootstrap**. For the last example, instead of sampling from the empirical cdf \hat{F}_n , we sample randomly from the normal distribution, using as mean \bar{x} and as standard deviation s , the sample standard deviation. The R function `bootse2.R` performs this parametric bootstrap. For our run on the data set in the example, it computed the standard error as 3.162918. Notice how close the three estimated standard deviations are.

Which bootstrap, nonparametric or parametric, should we use? We recommend the nonparametric bootstrap in general. The strong model assumptions are not needed for its validity. See pages 55–56 of Efron and Tibshirani (1993) for discussion.

EXERCISES

7.6.1. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta, 1)$, $-\infty < \theta < \infty$. Find the MVUE of θ^2 .

Hint: First determine $E(\bar{X}^2)$.

7.6.2. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(0, \theta)$. Then $Y = \sum X_i^2$ is a complete sufficient statistic for θ . Find the MVUE of θ^2 .

7.6.3. Consider Example 7.6.3 where the parameter of interest is $P(X < c)$ for X distributed $N(\theta, 1)$. Modify the R function `bootse1.R` so that for a specified value of c it returns the MVUE of $P(X < c)$ and the bootstrap standard error of the estimate. Run your function on the data in `ex763data.rda` with $c = 11$ and 3,000 bootstraps. These data are generated from a $N(10, 1)$ distribution. Report (a) the true parameter, (b) the MVUE, and (c) the bootstrap standard error.

7.6.4. For Example 7.6.4, modify the R function `bootse1.R` so that the estimate is the median not the mean. Using 3,000 bootstraps, run your function on the data set discussed in the example and report (a) the estimate and (b) the bootstrap standard error.

7.6.5. Let X_1, X_2, \dots, X_n be a random sample from a uniform $(0, \theta)$ distribution. Continuing with Example 7.6.2, find the MVUEs for the following functions of θ .

(a) $g(\theta) = \frac{\theta^2}{12}$, i.e., the variance of the distribution.

(b) $g(\theta) = \frac{1}{\theta}$, i.e., the pdf of the distribution.

(c) For t real, $g(\theta) = \frac{e^{t\theta}-1}{t\theta}$, i.e., the mgf of the distribution.

7.6.6. Let X_1, X_2, \dots, X_n be a random sample from a Poisson distribution with parameter $\theta > 0$.

- (a) Find the MVUE of $P(X \leq 1) = (1 + \theta)e^{-\theta}$.

Hint: Let $u(x_1) = 1$, $x_1 \leq 1$, zero elsewhere, and find $E[u(X_1)|Y = y]$, where $Y = \sum_1^n X_i$.

- (b) Express the MVUE as a function of the mle of θ .
(c) Determine the asymptotic distribution of the mle of θ .
(d) Obtain the mle of $P(X \leq 1)$. Then use Theorem 5.2.9 to determine its asymptotic distribution.

7.6.7. Let X_1, X_2, \dots, X_n denote a random sample from a Poisson distribution with parameter $\theta > 0$. From Remark 7.6.1, we know that $E[(-1)^{X_1}] = e^{-2\theta}$.

- (a) Show that $E[(-1)^{X_1}|Y_1 = y_1] = (1 - 2/n)^{y_1}$, where $Y_1 = X_1 + X_2 + \dots + X_n$.
Hint: First show that the conditional pdf of X_1, X_2, \dots, X_{n-1} , given $Y_1 = y_1$, is multinomial, and hence that of X_1 , given $Y_1 = y_1$, is $b(y_1, 1/n)$.
(b) Show that the mle of $e^{-2\theta}$ is $e^{-2\bar{X}}$.
(c) Since $y_1 = n\bar{x}$, show that $(1 - 2/n)^{y_1}$ is approximately equal to $e^{-2\bar{x}}$ when n is large.

7.6.8. As in Example 7.6.3, let X_1, X_2, \dots, X_n be a random sample of size $n > 1$ from a distribution that is $N(\theta, 1)$. Show that the joint distribution of X_1 and \bar{X} is bivariate normal with mean vector (θ, θ) , variances $\sigma_1^2 = 1$ and $\sigma_2^2 = 1/n$, and correlation coefficient $\rho = 1/\sqrt{n}$.

7.6.9. Let a random sample of size n be taken from a distribution that has the pdf $f(x; \theta) = (1/\theta) \exp(-x/\theta) I_{(0, \infty)}(x)$. Find the mle and MVUE of $P(X \leq 2)$.

7.6.10. Let X_1, X_2, \dots, X_n be a random sample with the common pdf $f(x) = \theta^{-1} e^{-x/\theta}$, for $x > 0$, zero elsewhere; that is, $f(x)$ is a $\Gamma(1, \theta)$ pdf.

- (a) Show that the statistic $\bar{X} = n^{-1} \sum_{i=1}^n X_i$ is a complete and sufficient statistic for θ .
(b) Determine the MVUE of θ .
(c) Determine the mle of θ .
(d) Often, though, this pdf is written as $f(x) = \tau e^{-\tau x}$, for $x > 0$, zero elsewhere. Thus $\tau = 1/\theta$. Use Theorem 6.1.2 to determine the mle of τ .
(e) Show that the statistic $\bar{X} = n^{-1} \sum_{i=1}^n X_i$ is a complete and sufficient statistic for τ . Show that $(n-1)/(n\bar{X})$ is the MVUE of $\tau = 1/\theta$. Hence, as usual, the reciprocal of the mle of θ is the mle of $1/\theta$, but, in this situation, the reciprocal of the MVUE of θ is not the MVUE of $1/\theta$.
(f) Compute the variances of each of the unbiased estimators in parts (b) and (e).

7.6.11. Consider the situation of the last exercise, but suppose we have the following two independent random samples: (1) X_1, X_2, \dots, X_n is a random sample with the common pdf $f_X(x) = \theta^{-1}e^{-x/\theta}$, for $x > 0$, zero elsewhere, and (2) Y_1, Y_2, \dots, Y_n is a random sample with common pdf $f_Y(y) = \theta e^{-\theta y}$, for $y > 0$, zero elsewhere. The last exercise suggests that, for some constant c , $Z = c\bar{X}/\bar{Y}$ might be an unbiased estimator of θ^2 . Find this constant c and the variance of Z .

Hint: Show that $\bar{X}/(\theta^2\bar{Y})$ has an F -distribution.

7.6.12. Obtain the asymptotic distribution of the MVUE in Example 7.6.1 for the case $\theta = 1/2$.

7.7 The Case of Several Parameters

In many of the interesting problems we encounter, the pdf or pmf may not depend upon a single parameter θ , but perhaps upon two (or more) parameters. In general, our parameter space Ω is a subset of R^p , but in many of our examples p is 2.

Definition 7.7.1. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that has pdf or pmf $f(x; \boldsymbol{\theta})$, where $\boldsymbol{\theta} \in \Omega \subset R^p$. Let \mathcal{S} denote the support of X . Let \mathbf{Y} be an m -dimensional random vector of statistics $\mathbf{Y} = (Y_1, \dots, Y_m)'$, where $Y_i = u_i(X_1, X_2, \dots, X_n)$, for $i = 1, \dots, m$. Denote the pdf or pmf of \mathbf{Y} by $f_{\mathbf{Y}}(\mathbf{y}; \boldsymbol{\theta})$ for $\mathbf{y} \in R^m$. The random vector of statistics \mathbf{Y} is **jointly sufficient** for $\boldsymbol{\theta}$ if and only if

$$\frac{\prod_{i=1}^n f(x_i; \boldsymbol{\theta})}{f_{\mathbf{Y}}(\mathbf{y}; \boldsymbol{\theta})} = H(x_1, x_2, \dots, x_n), \quad \text{for all } x_i \in \mathcal{S},$$

where $H(x_1, x_2, \dots, x_n)$ does not depend upon $\boldsymbol{\theta}$.

In general, $m \neq p$, i.e., the number of sufficient statistics does not have to be the same as the number of parameters, but in most of our examples this is the case.

As may be anticipated, the factorization theorem can be extended. In our notation it can be stated in the following manner. The vector of statistics \mathbf{Y} is jointly sufficient for the parameter $\boldsymbol{\theta} \in \Omega$ if and only if we can find two nonnegative functions k_1 and k_2 such that

$$\prod_{i=1}^n f(x_i; \boldsymbol{\theta}) = k_1(\mathbf{y}; \boldsymbol{\theta})k_2(x_1, \dots, x_n), \quad \text{for all } x_i \in \mathcal{S}, \quad (7.7.1)$$

where the function $k_2(x_1, x_2, \dots, x_n)$ does not depend upon $\boldsymbol{\theta}$.

Example 7.7.1. Let X_1, X_2, \dots, X_n be a random sample from a distribution having pdf

$$f(x; \theta_1, \theta_2) = \begin{cases} \frac{1}{2\theta_2} & \theta_1 - \theta_2 < x < \theta_1 + \theta_2 \\ 0 & \text{elsewhere,} \end{cases}$$

where $-\infty < \theta_1 < \infty$, $0 < \theta_2 < \infty$. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics. The joint pdf of Y_1 and Y_n is given by

$$f_{Y_1, Y_n}(y_1, y_n; \theta_1, \theta_2) = \frac{n(n-1)}{(2\theta_2)^n} (y_n - y_1)^{n-2}, \quad \theta_1 - \theta_2 < y_1 < y_n < \theta_1 + \theta_2,$$

and equals zero elsewhere. Accordingly, the joint pdf of X_1, X_2, \dots, X_n can be written, for all points in its support (all x_i such that $\theta_1 - \theta_2 < x_i < \theta_1 + \theta_2$),

$$\left(\frac{1}{2\theta_2}\right)^n = \frac{n(n-1)[\max(x_i) - \min(x_i)]^{n-2}}{(2\theta_2)^n} \left(\frac{1}{n(n-1)[\max(x_i) - \min(x_i)]^{n-2}}\right).$$

Since $\min(x_i) \leq x_j \leq \max(x_i)$, $j = 1, 2, \dots, n$, the last factor does not depend upon the parameters. Either the definition or the factorization theorem assures us that Y_1 and Y_n are joint sufficient statistics for θ_1 and θ_2 . ■

The concept of a complete family of probability density functions is generalized as follows: Let

$$\{f(v_1, v_2, \dots, v_k; \boldsymbol{\theta}) : \boldsymbol{\theta} \in \Omega\}$$

denote a family of pdfs of k random variables V_1, V_2, \dots, V_k that depends upon the p -dimensional vector of parameters $\boldsymbol{\theta} \in \Omega$. Let $u(v_1, v_2, \dots, v_k)$ be a function of v_1, v_2, \dots, v_k (but not a function of any or all of the parameters). If

$$E[u(V_1, V_2, \dots, V_k)] = 0$$

for all $\boldsymbol{\theta} \in \Omega$ implies that $u(v_1, v_2, \dots, v_k) = 0$ at all points (v_1, v_2, \dots, v_k) , except on a set of points that has probability zero for all members of the family of probability density functions, we shall say that the family of probability density functions is a complete family.

In the case where $\boldsymbol{\theta}$ is a vector, we generally consider best estimators of functions of $\boldsymbol{\theta}$, that is, parameters δ , where $\delta = g(\boldsymbol{\theta})$ for a specified function g . For example, suppose we are sampling from a $N(\theta_1, \theta_2)$ distribution, where θ_2 is the variance. Let $\boldsymbol{\theta} = (\theta_1, \theta_2)'$ and consider the two parameters $\delta_1 = g_1(\boldsymbol{\theta}) = \theta_1$ and $\delta_2 = g_2(\boldsymbol{\theta}) = \sqrt{\theta_2}$. Hence we are interested in best estimates of δ_1 and δ_2 .

The Rao–Blackwell, Lehmann–Scheffé theory outlined in Sections 7.3 and 7.4 extends naturally to this vector case. Briefly, suppose $\delta = g(\boldsymbol{\theta})$ is the parameter of interest and \mathbf{Y} is a vector of sufficient and complete statistics for $\boldsymbol{\theta}$. Let T be a statistic that is a function of \mathbf{Y} , such as $T = T(\mathbf{Y})$. If $E(T) = \delta$, then T is the unique MVUE of δ .

The remainder of our treatment of the case of several parameters is restricted to probability density functions that represent what we shall call regular cases of the exponential class. Here $m = p$.

Definition 7.7.2. Let X be a random variable with pdf or pmf $f(x; \boldsymbol{\theta})$, where the vector of parameters $\boldsymbol{\theta} \in \Omega \subset R^m$. Let \mathcal{S} denote the support of X . If X is continuous, assume that $\mathcal{S} = (a, b)$, where a or b may be $-\infty$ or ∞ , respectively. If X is discrete, assume that $\mathcal{S} = \{a_1, a_2, \dots\}$. Suppose $f(x; \boldsymbol{\theta})$ is of the form

$$f(x; \boldsymbol{\theta}) = \begin{cases} \exp \left[\sum_{j=1}^m p_j(\boldsymbol{\theta}) K_j(x) + H(x) + q(\theta_1, \theta_2, \dots, \theta_m) \right] & \text{for all } x \in \mathcal{S} \\ 0 & \text{elsewhere.} \end{cases} \quad (7.7.2)$$

Then we say this pdf or pmf is a member of the **exponential class**. We say it is a **regular case** of the exponential family if, in addition,

1. the support does not depend on the vector of parameters $\boldsymbol{\theta}$,
2. the space Ω contains a nonempty, m -dimensional open rectangle,
3. the $p_j(\boldsymbol{\theta})$, $j = 1, \dots, m$, are nontrivial, functionally independent, continuous functions of $\boldsymbol{\theta}$,
4. and, depending on whether X is continuous or discrete, one of the following holds, respectively:
 - (a) if X is a continuous random variable, then the m derivatives $K'_j(x)$, for $j = 1, 2, \dots, m$, are continuous for $a < x < b$ and no one is a linear homogeneous function of the others, and $H(x)$ is a continuous function of x , $a < x < b$.
 - (b) if X is discrete, the $K_j(x)$, $j = 1, 2, \dots, m$, are nontrivial functions of x on the support \mathcal{S} and no one is a linear homogeneous function of the others.

Let X_1, \dots, X_n be a random sample on X where the pdf or pmf of X is a regular case of the exponential class with the same notation as in Definition 7.7.2. It follows from (7.7.2) that the joint pdf or pmf of the sample is given by

$$\prod_{i=1}^n f(x_i; \boldsymbol{\theta}) = \exp \left[\sum_{j=1}^m p_j(\boldsymbol{\theta}) \sum_{i=1}^n K_j(x_i) + nq(\boldsymbol{\theta}) \right] \exp \left[\sum_{i=1}^n H(x_i) \right], \quad (7.7.3)$$

for all $x_i \in \mathcal{S}$. In accordance with the factorization theorem, the statistics

$$Y_1 = \sum_{i=1}^n K_1(x_i), \quad Y_2 = \sum_{i=1}^n K_2(x_i), \dots, Y_m = \sum_{i=1}^n K_m(x_i)$$

are joint sufficient statistics for the m -dimensional vector of parameters $\boldsymbol{\theta}$. It is left as an exercise to prove that the joint pdf of $\mathbf{Y} = (Y_1, \dots, Y_m)'$ is of the form

$$R(\mathbf{y}) \exp \left[\sum_{j=1}^m p_j(\boldsymbol{\theta}) y_j + nq(\boldsymbol{\theta}) \right], \quad (7.7.4)$$

at points of positive probability density. These points of positive probability density and the function $R(\mathbf{y})$ do not depend upon the vector of parameters $\boldsymbol{\theta}$. Moreover, in accordance with a theorem in analysis, it can be asserted that in a regular case of the exponential class, the family of probability density functions of these joint sufficient statistics Y_1, Y_2, \dots, Y_m is complete when $n > m$. In accordance with a convention previously adopted, we shall refer to Y_1, Y_2, \dots, Y_m as **joint complete sufficient statistics** for the vector of parameters $\boldsymbol{\theta}$.

Example 7.7.2. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta_1, \theta_2)$, $-\infty < \theta_1 < \infty$, $0 < \theta_2 < \infty$. Thus the pdf $f(x; \theta_1, \theta_2)$ of the distribution may be written as

$$f(x; \theta_1, \theta_2) = \exp \left(\frac{-1}{2\theta_2} x^2 + \frac{\theta_1}{\theta_2} x - \frac{\theta_1^2}{2\theta_2} - \ln \sqrt{2\pi\theta_2} \right).$$

Therefore, we can take $K_1(x) = x^2$ and $K_2(x) = x$. Consequently, the statistics

$$Y_1 = \sum_1^n X_i^2 \quad \text{and} \quad Y_2 = \sum_1^n X_i$$

are joint complete sufficient statistics for θ_1 and θ_2 . Since the relations

$$Z_1 = \frac{Y_2}{n} = \bar{X}, \quad Z_2 = \frac{Y_1 - Y_2^2/n}{n-1} = \frac{\sum(X_i - \bar{X})^2}{n-1}$$

define a one-to-one transformation, Z_1 and Z_2 are also joint complete sufficient statistics for θ_1 and θ_2 . Moreover,

$$E(Z_1) = \theta_1 \quad \text{and} \quad E(Z_2) = \theta_2.$$

From completeness, we have that Z_1 and Z_2 are the only functions of Y_1 and Y_2 that are unbiased estimators of θ_1 and θ_2 , respectively. Hence Z_1 and Z_2 are the unique minimum variance estimators of θ_1 and θ_2 , respectively. The MVUE of the standard deviation $\sqrt{\theta_2}$ is derived in Exercise 7.7.5. ■

In this section we have extended the concepts of sufficiency and completeness to the case where $\boldsymbol{\theta}$ is a p -dimensional vector. We now extend these concepts to the case where \mathbf{X} is a k -dimensional random vector. We only consider the regular exponential class.

Suppose \mathbf{X} is a k -dimensional random vector with pdf or pmf $f(\mathbf{x}; \boldsymbol{\theta})$, where $\boldsymbol{\theta} \in \Omega \subset R^p$. Let $\mathcal{S} \subset R^k$ denote the support of \mathbf{X} . Suppose $f(\mathbf{x}; \boldsymbol{\theta})$ is of the form

$$f(\mathbf{x}; \boldsymbol{\theta}) = \begin{cases} \exp \left[\sum_{j=1}^m p_j(\boldsymbol{\theta}) K_j(\mathbf{x}) + H(\mathbf{x}) + q(\boldsymbol{\theta}) \right] & \text{for all } \mathbf{x} \in \mathcal{S} \\ 0 & \text{elsewhere.} \end{cases} \quad (7.7.5)$$

Then we say this pdf or pmf is a member of the **exponential class**. If, in addition, $p = m$, the support does not depend on the vector of parameters $\boldsymbol{\theta}$, and conditions similar to those of Definition 7.7.2 hold, then we say this pdf is a **regular case** of the exponential class.

Suppose that $\mathbf{X}_1, \dots, \mathbf{X}_n$ constitute a random sample on \mathbf{X} . Then the statistics,

$$Y_j = \sum_{i=1}^n K_j(\mathbf{X}_i), \quad \text{for } j = 1, \dots, m, \quad (7.7.6)$$

are sufficient and complete statistics for $\boldsymbol{\theta}$. Let $\mathbf{Y} = (Y_1, \dots, Y_m)'$. Suppose $\delta = g(\boldsymbol{\theta})$ is a parameter of interest. If $T = h(\mathbf{Y})$ for some function h and $E(T) = \delta$ then T is the unique minimum variance unbiased estimator of δ .

Example 7.7.3 (Multinomial). In Example 6.4.5, we consider the mles of the multinomial distribution. In this example we determine the MVUEs of several of the parameters. As in Example 6.4.5, consider a random trial that can result in one, and only one, of k outcomes or categories. Let X_j be 1 or 0 depending on whether the j th outcome does or does not occur, for $j = 1, \dots, k$. Suppose the probability

that outcome j occurs is p_j ; hence, $\sum_{j=1}^k p_j = 1$. Let $\mathbf{X} = (X_1, \dots, X_{k-1})'$ and $\mathbf{p} = (p_1, \dots, p_{k-1})'$. The distribution of \mathbf{X} is multinomial and can be found in expression (6.4.18), which can be reexpressed as

$$f(\mathbf{x}, \mathbf{p}) = \exp \left\{ \sum_{j=1}^{k-1} \left(\log \left[\frac{p_j}{1 - \sum_{i \neq k} p_i} \right] \right) x_j + \log \left(1 - \sum_{i \neq k} p_i \right) \right\}.$$

Because this a regular case of the exponential family, the following statistics, resulting from a random sample $\mathbf{X}_1, \dots, \mathbf{X}_n$ from the distribution of \mathbf{X} , are jointly sufficient and complete for the parameters $\mathbf{p} = (p_1, \dots, p_{k-1})'$:

$$Y_j = \sum_{i=1}^n X_{ij}, \quad \text{for } j = 1, \dots, k-1.$$

Each random variable X_{ij} is Bernoulli with parameter p_j and the variables X_{ij} are independent for $i = 1, \dots, n$. Hence the variables Y_j are binomial(n, p_j) for $j = 1, \dots, k$. Thus the MVUE of p_j is the statistic $n^{-1}Y_j$.

Next, we shall find the MVUE of $p_j p_l$, for $j \neq l$. Exercise 7.7.8 shows that the mle of $p_j p_l$ is $n^{-2}Y_j Y_l$. Recall from Section 3.1 that the conditional distribution of Y_j , given Y_l , is $b[n - Y_l, p_j / (1 - p_l)]$. As an initial guess at the MVUE, consider the mle, which, as shown by Exercise 7.7.8, is $n^{-2}Y_j Y_l$. Hence

$$\begin{aligned} E[n^{-2}Y_j Y_l] &= \frac{1}{n^2} E[E(Y_j Y_l | Y_l)] = \frac{1}{n^2} E[Y_l E(Y_j | Y_l)] \\ &= \frac{1}{n^2} E \left[Y_l (n - Y_l) \frac{p_j}{1 - p_l} \right] = \frac{1}{n^2} \frac{p_j}{1 - p_l} \{E[n Y_l] - E[Y_l^2]\} \\ &= \frac{1}{n^2} \frac{p_j}{1 - p_l} \{n^2 p_l - n p_l (1 - p_l) - n^2 p_l^2\} \\ &= \frac{1}{n^2} \frac{p_j}{1 - p_l} n p_l (n - 1)(1 - p_l) = \frac{(n-1)}{n} p_j p_l. \end{aligned}$$

Hence the MVUE of $p_j p_l$ is $\frac{1}{n(n-1)} Y_j Y_l$. ■

Example 7.7.4 (Multivariate Normal). Let \mathbf{X} have the multivariate normal distribution $N_k(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, where $\boldsymbol{\Sigma}$ is a positive definite $k \times k$ matrix. The pdf of \mathbf{X} is given in expression (3.5.16). In this case $\boldsymbol{\theta}$ is a $\{k + [k(k+1)/2]\}$ -dimensional vector whose first k components consist of the mean vector $\boldsymbol{\mu}$ and whose last $\frac{k(k+1)}{2}$ components consist of the componentwise variances σ_i^2 and the covariances σ_{ij} , for $j \geq i$. The density of \mathbf{X} can be written as

$$f_{\mathbf{x}}(\mathbf{x}) = \exp \left\{ -\frac{1}{2} \mathbf{x}' \boldsymbol{\Sigma}^{-1} \mathbf{x} + \boldsymbol{\mu}' \boldsymbol{\Sigma}^{-1} \mathbf{x} - \frac{1}{2} \boldsymbol{\mu}' \boldsymbol{\Sigma}^{-1} \boldsymbol{\mu} - \frac{1}{2} \log |\boldsymbol{\Sigma}| - \frac{k}{2} \log 2\pi \right\}, \quad (7.7.7)$$

for $\mathbf{x} \in R^k$. Hence, by (7.7.5), the multivariate normal pdf is a regular case of the exponential class of distributions. We need only identify the functions $K(\mathbf{x})$. The second term in the exponent on the right side of (7.7.7) can be written as $(\boldsymbol{\mu}' \boldsymbol{\Sigma}^{-1}) \mathbf{x}$;

hence, $K_1(\mathbf{x}) = \mathbf{x}$. The first term is easily seen to be a linear combination of the products $x_i x_j$, $i, j = 1, 2, \dots, k$, which are the entries of the matrix $\mathbf{x}\mathbf{x}'$. Hence we can take $K_2(\mathbf{x}) = \mathbf{x}\mathbf{x}'$. Now, let $\mathbf{X}_1, \dots, \mathbf{X}_n$ be a random sample on \mathbf{X} . Based on (7.7.7) then, a set of sufficient and complete statistics is given by

$$\mathbf{Y}_1 = \sum_{i=1}^n \mathbf{X}_i \text{ and } \mathbf{Y}_2 = \sum_{i=1}^n \mathbf{X}_i \mathbf{X}'_i. \quad (7.7.8)$$

Note that \mathbf{Y}_1 is a vector of k statistics and that \mathbf{Y}_2 is a $k \times k$ symmetric matrix. Because the matrix is symmetric, we can eliminate the bottom-half [elements (i, j) with $i > j$] of the matrix, which results in $\{k + [k(k+1)]\}$ complete sufficient statistics, i.e., as many complete sufficient statistics as there are parameters.

Based on marginal distributions, it is easy to show that $\bar{X}_j = n^{-1} \sum_{i=1}^n X_{ij}$ is the MVUE of μ_j and that $(n-1)^{-1} \sum_{i=1}^n (X_{ij} - \bar{X}_j)^2$ is the MVUE of σ_j^2 . The MVUEs of the covariance parameters are obtained in Exercise 7.7.9. ■

For our last example, we consider a case where the set of parameters is the cdf.

Example 7.7.5. Let X_1, X_2, \dots, X_n be a random sample having the common continuous cdf $F(x)$. Let $Y_1 < Y_2 < \dots < Y_n$ denote the corresponding order statistics. Note that given $Y_1 = y_1, Y_2 = y_2, \dots, Y_n = y_n$, the conditional distribution of X_1, X_2, \dots, X_n is discrete with probability $\frac{1}{n!}$ on each of the $n!$ permutations of the vector (y_1, y_2, \dots, y_n) , [because $F(x)$ is continuous, we can assume that each of the values y_1, y_2, \dots, y_n is distinct]. That is, the conditional distribution does not depend on $F(x)$. Hence, by the definition of sufficiency, the order statistics are sufficient for $F(x)$. Furthermore, while the proof is beyond the scope of this book, it can be shown that the order statistics are also complete; see page 72 of Lehmann and Casella (1998).

Let $T = T(x_1, x_2, \dots, x_n)$ be any statistic that is *symmetric in its arguments*; i.e., $T(x_1, x_2, \dots, x_n) = T(x_{i_1}, x_{i_2}, \dots, x_{i_n})$ for any permutation $(x_{i_1}, x_{i_2}, \dots, x_{i_n})$ of (x_1, x_2, \dots, x_n) . Then T is a function of the order statistics. This is useful in determining MVUEs for this situation; see Exercises 7.7.12 and 7.7.13. ■

EXERCISES

7.7.1. Let $Y_1 < Y_2 < Y_3$ be the order statistics of a random sample of size 3 from the distribution with pdf

$$f(x; \theta_1, \theta_2) = \begin{cases} \frac{1}{\theta_2} \exp\left(-\frac{x-\theta_1}{\theta_2}\right) & \theta_1 < x < \infty, \quad -\infty < \theta_1 < \infty, \quad 0 < \theta_2 < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Find the joint pdf of $Z_1 = Y_1$, $Z_2 = Y_2$, and $Z_3 = Y_1 + Y_2 + Y_3$. The corresponding transformation maps the space $\{(y_1, y_2, y_3) : \theta_1 < y_1 < y_2 < y_3 < \infty\}$ onto the space

$$\{(z_1, z_2, z_3) : \theta_1 < z_1 < z_2 < (z_3 - z_1)/2 < \infty\}.$$

Show that Z_1 and Z_3 are joint sufficient statistics for θ_1 and θ_2 .

7.7.2. Let X_1, X_2, \dots, X_n be a random sample from a distribution that has a pdf of the form (7.7.2) of this section. Show that $Y_1 = \sum_{i=1}^n K_1(X_i), \dots, Y_m = \sum_{i=1}^m K_m(X_i)$ have a joint pdf of the form (7.7.4) of this section.

7.7.3. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ denote a random sample of size n from a bivariate normal distribution with means μ_1 and μ_2 , positive variances σ_1^2 and σ_2^2 , and correlation coefficient ρ . Show that $\sum_1^n X_i, \sum_1^n Y_i, \sum_1^n X_i^2, \sum_1^n Y_i^2$, and $\sum_1^n X_i Y_i$ are joint complete sufficient statistics for the five parameters. Are $\bar{X} = \sum_1^n X_i/n, \bar{Y} = \sum_1^n Y_i/n, S_1^2 = \sum_1^n (X_i - \bar{X})^2/(n-1), S_2^2 = \sum_1^n (Y_i - \bar{Y})^2/(n-1)$, and $\sum_1^n (X_i - \bar{X})(Y_i - \bar{Y})/(n-1)S_1 S_2$ also joint complete sufficient statistics for these parameters?

7.7.4. Let the pdf $f(x; \theta_1, \theta_2)$ be of the form

$$\exp[p_1(\theta_1, \theta_2)K_1(x) + p_2(\theta_1, \theta_2)K_2(x) + H(x) + q_1(\theta_1, \theta_2)], \quad a < x < b,$$

zero elsewhere. Suppose that $K'_1(x) = cK'_2(x)$. Show that $f(x; \theta_1, \theta_2)$ can be written in the form

$$\exp[p(\theta_1, \theta_2)K_2(x) + H(x) + q(\theta_1, \theta_2)], \quad a < x < b,$$

zero elsewhere. This is the reason why it is required that no one $K'_j(x)$ be a linear homogeneous function of the others, that is, so that the number of sufficient statistics equals the number of parameters.

7.7.5. In Example 7.7.2:

- (a) Find the MVUE of the standard deviation $\sqrt{\theta_2}$.
- (b) Modify the R function `bootse1.R` so that it returns the estimate in (a) and its bootstrap standard error. Run it on the Bavarian forest data discussed in Example 4.1.3, where the response is the concentration of sulfur dioxide. Using 3,000 bootstraps, report the estimate and its bootstrap standard error.

7.7.6. Let X_1, X_2, \dots, X_n be a random sample from the uniform distribution with pdf $f(x; \theta_1, \theta_2) = 1/(2\theta_2)$, $\theta_1 - \theta_2 < x < \theta_1 + \theta_2$, where $-\infty < \theta_1 < \infty$ and $\theta_2 > 0$, and the pdf is equal to zero elsewhere.

- (a) Show that $Y_1 = \min(X_i)$ and $Y_n = \max(X_i)$, the joint sufficient statistics for θ_1 and θ_2 , are complete.
- (b) Find the MVUEs of θ_1 and θ_2 .

7.7.7. Let X_1, X_2, \dots, X_n be a random sample from $N(\theta_1, \theta_2)$.

- (a) If the constant b is defined by the equation $P(X \leq b) = p$ where p is specified, find the mle and the MVUE of b .
- (b) Modify the R function `bootse1.R` so that it returns the MVUE of Part (a) and its bootstrap standard error.
- (c) Run your function in Part (b) on the data set discussed in Example 7.6.4 for $p = 0.75$ and 3,000 bootstraps.

7.7.8. In the notation of Example 7.7.3, show that the mle of $p_j p_l$ is $n^{-2} Y_j Y_l$.

7.7.9. Refer to Example 7.7.4 on sufficiency for the multivariate normal model.

(a) Determine the MVUE of the covariance parameters σ_{ij} .

(b) Let $g = \sum_{i=1}^k a_i \mu_i$, where a_1, \dots, a_k are specified constants. Find the MVUE for g .

7.7.10. In a personal communication, LeRoy Folks noted that the inverse Gaussian pdf

$$f(x; \theta_1, \theta_2) = \left(\frac{\theta_2}{2\pi x^3} \right)^{1/2} \exp \left[\frac{-\theta_2(x - \theta_1)^2}{2\theta_1^2 x} \right], \quad 0 < x < \infty, \quad (7.7.9)$$

where $\theta_1 > 0$ and $\theta_2 > 0$, is often used to model lifetimes. Find the complete sufficient statistics for (θ_1, θ_2) if X_1, X_2, \dots, X_n is a random sample from the distribution having this pdf.

7.7.11. Let X_1, X_2, \dots, X_n be a random sample from a $N(\theta_1, \theta_2)$ distribution.

(a) Show that $E[(X_1 - \theta_1)^4] = 3\theta_2^2$.

(b) Find the MVUE of $3\theta_2^2$.

7.7.12. Let X_1, \dots, X_n be a random sample from a distribution of the continuous type with cdf $F(x)$. Suppose the mean, $\mu = E(X_1)$, exists. Using Example 7.7.5, show that the sample mean, $\bar{X} = n^{-1} \sum_{i=1}^n X_i$, is the MVUE of μ .

7.7.13. Let X_1, \dots, X_n be a random sample from a distribution of the continuous type with cdf $F(x)$. Let $\theta = P(X_1 \leq a) = F(a)$, where a is known. Show that the proportion $n^{-1} \#\{X_i \leq a\}$ is the MVUE of θ .

7.8 Minimal Sufficiency and Ancillary Statistics

In the study of statistics, it is clear that we want to reduce the data contained in the entire sample as much as possible without losing relevant information about the important characteristics of the underlying distribution. That is, a large collection of numbers in the sample is not as meaningful as a few good summary statistics of those data. Sufficient statistics, if they exist, are valuable because we know that the statisticians with those summary measures have as much information as the statistician with the entire sample. Sometimes, however, there are several sets of joint sufficient statistics, and thus we would like to find the simplest one of these sets. For illustration, in a sense, the observations X_1, X_2, \dots, X_n , $n > 2$, of a random sample from $N(\theta_1, \theta_2)$ could be thought of as joint sufficient statistics for θ_1 and θ_2 . We know, however, that we can use \bar{X} and S^2 as joint sufficient statistics for those parameters, which is a great simplification over using X_1, X_2, \dots, X_n , particularly if n is large.

In most instances in this chapter, we have been able to find a single sufficient statistic for one parameter or two joint sufficient statistics for two parameters. Possibly the most complicated cases considered so far are given in Example 7.7.3, in

which we find $k + k(k+1)/2$ joint sufficient statistics for $k + k(k+1)/2$ parameters; or the multivariate normal distribution given in Example 7.7.4; or in the use the order statistics of a random sample for some completely unknown distribution of the continuous type as in Example 7.7.5.

What we would like to do is to change from one set of joint sufficient statistics to another, always reducing the number of statistics involved until we cannot go any further without losing the sufficiency of the resulting statistics. Those statistics that are there at the end of this reduction are called **minimal sufficient statistics**. These are sufficient for the parameters and are functions of every other set of sufficient statistics for those same parameters. Often, if there are k parameters, we can find k joint sufficient statistics that are minimal. In particular, if there is one parameter, we can often find a single sufficient statistic that is minimal. Most of the earlier examples that we have considered illustrate this point, but this is not always the case, as shown by the following example.

Example 7.8.1. Let X_1, X_2, \dots, X_n be a random sample from the uniform distribution over the interval $(\theta - 1, \theta + 1)$ having pdf

$$f(x; \theta) = \left(\frac{1}{2}\right) I_{(\theta-1, \theta+1)}(x), \quad \text{where } -\infty < \theta < \infty.$$

The joint pdf of X_1, X_2, \dots, X_n equals the product of $(\frac{1}{2})^n$ and certain indicator functions, namely,

$$\left(\frac{1}{2}\right)^n \prod_{i=1}^n I_{(\theta-1, \theta+1)}(x_i) = \left(\frac{1}{2}\right)^n \{I_{(\theta-1, \theta+1)}[\min(x_i)]\} \{I_{(\theta-1, \theta+1)}[\max(x_i)]\},$$

because $\theta - 1 < \min(x_i) \leq x_j \leq \max(x_i) < \theta + 1$, $j = 1, 2, \dots, n$. Thus the order statistics $Y_1 = \min(X_i)$ and $Y_n = \max(X_i)$ are the sufficient statistics for θ . These two statistics actually are minimal for this one parameter, as we cannot reduce the number of them to less than two and still have sufficiency. ■

There is an observation that helps us see that almost all the sufficient statistics that we have studied thus far are minimal. We have noted that the mle $\hat{\theta}$ of θ is a function of one or more sufficient statistics, when the latter exists. Suppose that this mle $\hat{\theta}$ is also sufficient. Since this sufficient statistic $\hat{\theta}$ is a function of the other sufficient statistics, by Theorem 7.3.2, it must be minimal. For example, we have

1. The mle $\hat{\theta} = \bar{X}$ of θ in $N(\theta, \sigma^2)$, σ^2 known, is a minimal sufficient statistic for θ .
2. The mle $\hat{\theta} = \bar{X}$ of θ in a Poisson distribution with mean θ is a minimal sufficient statistic for θ .
3. The mle $\hat{\theta} = Y_n = \max(X_i)$ of θ in the uniform distribution over $(0, \theta)$ is a minimal sufficient statistic for θ .
4. The maximum likelihood estimators $\hat{\theta}_1 = \bar{X}$ and $\hat{\theta}_2 = [(n-1)/n]S^2$ of θ_1 and θ_2 in $N(\theta_1, \theta_2)$ are joint minimal sufficient statistics for θ_1 and θ_2 .

From these examples we see that the minimal sufficient statistics do not need to be unique, for any one-to-one transformation of them also provides minimal sufficient statistics. The linkage between minimal sufficient statistics and the mle, however, does not hold in many interesting instances. We illustrate this in the next two examples.

Example 7.8.2. Consider the model given in Example 7.8.1. There we noted that $Y_1 = \min(X_i)$ and $Y_n = \max(X_i)$ are joint sufficient statistics. Also, we have

$$\theta - 1 < Y_1 < Y_n < \theta + 1$$

or, equivalently,

$$Y_n - 1 < \theta < Y_1 + 1.$$

Hence, to maximize the likelihood function so that it equals $(\frac{1}{2})^n$, θ can be any value between $Y_n - 1$ and $Y_1 + 1$. For example, many statisticians take the mle to be the mean of these two endpoints, namely,

$$\hat{\theta} = \frac{Y_n - 1 + Y_1 + 1}{2} = \frac{Y_1 + Y_n}{2},$$

which is the midrange. We recognize, however, that this mle is not unique. Some might argue that since $\hat{\theta}$ is an mle of θ and since it is a function of the joint sufficient statistics, Y_1 and Y_n , for θ , it is a minimal sufficient statistic. This is not the case at all, for $\hat{\theta}$ is not even sufficient. Note that the mle must itself be a sufficient statistic for the parameter before it can be considered the minimal sufficient statistic. ■

Note that we can model the situation in the last example by

$$X_i = \theta + W_i, \tag{7.8.1}$$

where W_1, W_2, \dots, W_n are iid with the common uniform($-1, 1$) pdf. Hence this is an example of a location model. We discuss these models in general next.

Example 7.8.3. Consider a location model given by

$$X_i = \theta + W_i, \tag{7.8.2}$$

where W_1, W_2, \dots, W_n are iid with the common pdf $f(w)$ and common continuous cdf $F(w)$. From Example 7.7.5, we know that the order statistics $Y_1 < Y_2 < \dots < Y_n$ are a set of complete and sufficient statistics for this situation. Can we obtain a smaller set of minimal sufficient statistics? Consider the following four situations:

- (a) Suppose $f(w)$ is the $N(0, 1)$ pdf. Then we know that \bar{X} is both the MVUE and mle of θ . Also, $\bar{X} = n^{-1} \sum_{i=1}^n Y_i$, i.e., a function of the order statistics. Hence \bar{X} is minimal sufficient.
- (b) Suppose $f(w) = \exp\{-w\}$, for $w > 0$, zero elsewhere. Then the statistic Y_1 is a sufficient statistic as well as the mle, and thus is minimal sufficient.

- (c) Suppose $f(w)$ is the logistic pdf. As discussed in Example 6.1.2, the mle of θ exists and it is easy to compute. As shown on page 38 of Lehmann and Casella (1998), though, the order statistics are minimal sufficient for this situation. That is, no reduction is possible.
- (d) Suppose $f(w)$ is the Laplace pdf. It was shown in Example 6.1.1 that the median, Q_2 is the mle of θ , but it is not a sufficient statistic. Further, similar to the logistic pdf, it can be shown that the order statistics are minimal sufficient for this situation. ■

In general, the situation described in parts (c) and (d), where the mle is obtained rather easily while the set of minimal sufficient statistics is the set of order statistics and no reduction is possible, is the norm for location models.

There is also a relationship between a minimal sufficient statistic and completeness that is explained more fully in Lehmann and Scheffé (1950). Let us say simply and without explanation that for the cases in this book, complete sufficient statistics are minimal sufficient statistics. The converse is not true, however, by noting that in Example 7.8.1, we have

$$E \left[\frac{Y_n - Y_1}{2} - \frac{n-1}{n+1} \right] = 0, \quad \text{for all } \theta.$$

That is, there is a nonzero function of those minimal sufficient statistics, Y_1 and Y_n , whose expectation is zero for all θ .

There are other statistics that almost seem opposites of sufficient statistics. That is, while sufficient statistics contain all the information about the parameters, these other statistics, called **ancillary statistics**, have distributions free of the parameters and seemingly contain no information about those parameters. As an illustration, we know that the variance S^2 of a random sample from $N(\theta, 1)$ has a distribution that does not depend upon θ and hence is an ancillary statistic. Another example is the ratio $Z = X_1/(X_1 + X_2)$, where X_1, X_2 is a random sample from a gamma distribution with known parameter $\alpha > 0$ and unknown parameter $\beta = \theta$, because Z has a beta distribution that is free of θ . There are many examples of ancillary statistics, and we provide some rules that make them rather easy to find with certain models, which we present in the next three examples.

Example 7.8.4 (Location-Invariant Statistics). In Example 7.8.3, we introduced the location model. Recall that a random sample X_1, X_2, \dots, X_n follows this model if

$$X_i = \theta + W_i, \quad i = 1, \dots, n, \tag{7.8.3}$$

where $-\infty < \theta < \infty$ is a parameter and W_1, W_2, \dots, W_n are iid random variables with the pdf $f(w)$, which does not depend on θ . Then the common pdf of X_i is $f(x - \theta)$.

Let $Z = u(X_1, X_2, \dots, X_n)$ be a statistic such that

$$u(x_1 + d, x_2 + d, \dots, x_n + d) = u(x_1, x_2, \dots, x_n),$$

for all real d . Hence

$$Z = u(W_1 + \theta, W_2 + \theta, \dots, W_n + \theta) = u(W_1, W_2, \dots, W_n)$$

is a function of W_1, W_2, \dots, W_n alone (not of θ). Hence Z must have a distribution that does not depend upon θ . We call $Z = u(X_1, X_2, \dots, X_n)$ a **location-invariant statistic**.

Assuming a location model, the following are some examples of location-invariant statistics: the sample variance = S^2 , the sample range = $\max\{X_i\} - \min\{X_i\}$, the mean deviation from the sample median = $(1/n) \sum |X_i - \text{median}(X_i)|$, $X_1 + X_2 - X_3 - X_4$, $X_1 + X_3 - 2X_2$, $(1/n) \sum [X_i - \min(X_i)]$, and so on. To see that the range is location-invariant, note that

$$\begin{aligned}\max\{X_i\} - \theta &= \max\{X_i - \theta\} = \max\{W_i\} \\ \min\{X_i\} - \theta &= \min\{X_i - \theta\} = \min\{W_i\}.\end{aligned}$$

So,

$$\text{range} = \max\{X_i\} - \min\{X_i\} = \max\{X_i\} - \theta - (\min\{X_i\} - \theta) = \max\{W_i\} - \min\{W_i\}.$$

Hence the distribution of the range only depends on the distribution of the W_i s and, thus, it is location-invariant. For the location invariance of other statistics, see Exercise 7.8.4. ■

Example 7.8.5 (Scale-Invariant Statistics). Consider a random sample X_1, \dots, X_n that follows a **scale model**, i.e., a model of the form

$$X_i = \theta W_i, \quad i = 1, \dots, n, \tag{7.8.4}$$

where $\theta > 0$ and W_1, W_2, \dots, W_n are iid random variables with pdf $f(w)$, which does not depend on θ . Then the common pdf of X_i is $\theta^{-1} f(x/\theta)$. We call θ a scale parameter. Suppose that $Z = u(X_1, X_2, \dots, X_n)$ is a statistic such that

$$u(cx_1, cx_2, \dots, cx_n) = u(x_1, x_2, \dots, x_n)$$

for all $c > 0$. Then

$$Z = u(X_1, X_2, \dots, X_n) = u(\theta W_1, \theta W_2, \dots, \theta W_n) = u(W_1, W_2, \dots, W_n).$$

Since neither the joint pdf of W_1, W_2, \dots, W_n nor Z contains θ , the distribution of Z must not depend upon θ . We say that Z is a **scale-invariant statistic**.

The following are some examples of scale-invariant statistics: $X_1/(X_1 + X_2)$, $X_1^2 / \sum_1^n X_i^2$, $\min(X_i) / \max(X_i)$, and so on. The scale invariance of the first statistic follows from

$$\frac{X_1}{X_1 + X_2} = \frac{(\theta X_1)/\theta}{[(\theta X_1) + (\theta X_2)]/\theta} = \frac{W_1}{W_1 + W_2}.$$

The scale invariance of the other statistics is asked for in Exercise 7.8.5. ■

Example 7.8.6 (Location- and Scale-Invariant Statistics). Finally, consider a random sample X_1, X_2, \dots, X_n that follows a location and scale model as in Example 7.7.5. That is,

$$X_i = \theta_1 + \theta_2 W_i, \quad i = 1, \dots, n, \quad (7.8.5)$$

where W_i are iid with the common pdf $f(t)$ which is free of θ_1 and θ_2 . In this case, the pdf of X_i is $\theta_2^{-1} f((x - \theta_1)/\theta_2)$. Consider the statistic $Z = u(X_1, X_2, \dots, X_n)$, where

$$u(cx_1 + d, \dots, cx_n + d) = u(x_1, \dots, x_n).$$

Then

$$Z = u(X_1, \dots, X_n) = u(\theta_1 + \theta_2 W_1, \dots, \theta_1 + \theta_2 W_n) = u(W_1, \dots, W_n).$$

Since neither the joint pdf of W_1, \dots, W_n nor Z contains θ_1 and θ_2 , the distribution of Z must not depend upon θ_1 nor θ_2 . Statistics such as $Z = u(X_1, X_2, \dots, X_n)$ are called **location- and scale-invariant statistics**. The following are four examples of such statistics:

- (a) $T_1 = [\max(X_i) - \min(X_i)]/S$;
- (b) $T_2 = \sum_{i=1}^{n-1} (X_{i+1} - X_i)^2/S^2$;
- (c) $T_3 = (X_i - \bar{X})/S$;
- (d) $T_4 = |X_i - X_j|/S, ; i \neq j$.

Let $\bar{X} - \theta_1 = n^{-1} \sum_{i=1}^n (X_i - \theta_1)$. Then the location and scale invariance of the statistic in (d) follows from the two identities

$$\begin{aligned} S^2 &= \theta_2^2 \sum_{i=1}^n \left[\frac{X_i - \theta_1}{\theta_2} - \frac{\bar{X} - \theta_1}{\theta_2} \right]^2 = \theta_2^2 \sum_{i=1}^n (W_i - \bar{W})^2 \\ X_i - X_j &= \theta_2 \left[\frac{X_i - \theta_1}{\theta_2} - \frac{X_j - \theta_1}{\theta_2} \right] = \theta_2 (W_i - W_j). \end{aligned}$$

See Exercise 7.8.6 for the other statistics. ■

Thus, these location-invariant, scale-invariant, and location- and scale-invariant statistics provide good illustrations, with the appropriate model for the pdf, of ancillary statistics. Since an ancillary statistic and a complete (minimal) sufficient statistic are such opposites, we might believe that there is, in some sense, no relationship between the two. This is true, and in the next section we show that they are independent statistics.

EXERCISES

7.8.1. Let X_1, X_2, \dots, X_n be a random sample from each of the following distributions involving the parameter θ . In each case find the mle of θ and show that it is a sufficient statistic for θ and hence a minimal sufficient statistic.

- (a) $b(1, \theta)$, where $0 \leq \theta \leq 1$.
- (b) Poisson with mean $\theta > 0$.
- (c) Gamma with $\alpha = 3$ and $\beta = \theta > 0$.
- (d) $N(\theta, 1)$, where $-\infty < \theta < \infty$.
- (e) $N(0, \theta)$, where $0 < \theta < \infty$.

7.8.2. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from the uniform distribution over the closed interval $[-\theta, \theta]$ having pdf $f(x; \theta) = (1/2\theta)I_{[-\theta, \theta]}(x)$.

- (a) Show that Y_1 and Y_n are joint sufficient statistics for θ .
- (b) Argue that the mle of θ is $\hat{\theta} = \max(-Y_1, Y_n)$.
- (c) Demonstrate that the mle $\hat{\theta}$ is a sufficient statistic for θ and thus is a minimal sufficient statistic for θ .

7.8.3. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from a distribution with pdf

$$f(x; \theta_1, \theta_2) = \left(\frac{1}{\theta_2}\right) e^{-(x-\theta_1)/\theta_2} I_{(\theta_1, \infty)}(x),$$

where $-\infty < \theta_1 < \infty$ and $0 < \theta_2 < \infty$. Find the joint minimal sufficient statistics for θ_1 and θ_2 .

7.8.4. Continuing with Example 7.8.4, show that the following statistics are location-invariant:

- (a) The sample variance = S^2 .
- (b) The mean deviation from the sample median = $(1/n) \sum |X_i - \text{median}(X_i)|$.
- (c) $(1/n) \sum [X_i - \min(X_i)]$.

7.8.5. In Example 7.8.5, a scale model was presented and scale invariance was defined. Using the notation of this example, show that the following statistics are scale-invariant:

- (a) $X_1^2 / \sum_1^n X_i^2$.
- (b) $\min\{X_i\} / \max\{X_i\}$.

7.8.6. Obtain the location and scale invariance of the other statistics listed in Example 7.8.6, i.e., the statistics

- (a) $T_1 = [\max(X_i) - \min(X_i)]/S$.

$$(b) T_2 = \sum_{i=1}^{n-1} (X_{i+1} - X_i)^2 / S^2.$$

$$(c) T_3 = (X_i - \bar{X}) / S.$$

7.8.7. With random samples from each of the distributions given in Exercises 7.8.1(d), 7.8.2, and 7.8.3, define at least two ancillary statistics that are different from the examples given in the text. These examples illustrate, respectively, location-invariant, scale-invariant, and location- and scale-invariant statistics.

7.9 Sufficiency, Completeness, and Independence

We have noted that if we have a sufficient statistic Y_1 for a parameter θ , $\theta \in \Omega$, then $h(z|y_1)$, the conditional pdf of another statistic Z , given $Y_1 = y_1$, does not depend upon θ . If, moreover, Y_1 and Z are independent, the pdf $g_2(z)$ of Z is such that $g_2(z) = h(z|y_1)$, and hence $g_2(z)$ must not depend upon θ either. So the independence of a statistic Z and the sufficient statistic Y_1 for a parameter θ imply that the distribution of Z does not depend upon $\theta \in \Omega$. That is, Z is an ancillary statistic.

It is interesting to investigate a converse of that property. Suppose that the distribution of an ancillary statistic Z does not depend upon θ ; then are Z and the sufficient statistic Y_1 for θ independent? To begin our search for the answer, we know that the joint pdf of Y_1 and Z is $g_1(y_1; \theta)h(z|y_1)$, where $g_1(y_1; \theta)$ and $h(z|y_1)$ represent the marginal pdf of Y_1 and the conditional pdf of Z given $Y_1 = y_1$, respectively. Thus the marginal pdf of Z is

$$\int_{-\infty}^{\infty} g_1(y_1; \theta)h(z|y_1) dy_1 = g_2(z),$$

which, by hypothesis, does not depend upon θ . Because

$$\int_{-\infty}^{\infty} g_2(z)g_1(y_1; \theta) dy_1 = g_2(z),$$

it follows, by taking the difference of the last two integrals, that

$$\int_{-\infty}^{\infty} [g_2(z) - h(z|y_1)]g_1(y_1; \theta) dy_1 = 0 \quad (7.9.1)$$

for all $\theta \in \Omega$. Since Y_1 is sufficient statistic for θ , $h(z|y_1)$ does not depend upon θ . By assumption, $g_2(z)$ and hence $g_2(z) - h(z|y_1)$ do not depend upon θ . Now if the family $\{g_1(y_1; \theta) : \theta \in \Omega\}$ is complete, Equation (7.9.1) would require that

$$g_2(z) - h(z|y_1) = 0 \quad \text{or} \quad g_2(z) = h(z|y_1).$$

That is, the joint pdf of Y_1 and Z must be equal to

$$g_1(y_1; \theta)h(z|y_1) = g_1(y_1; \theta)g_2(z).$$

Accordingly, Y_1 and Z are independent, and we have proved the following theorem, which was considered in special cases by Neyman and Hogg and proved in general by Basu.

Theorem 7.9.1. Let X_1, X_2, \dots, X_n denote a random sample from a distribution having a pdf $f(x; \theta)$, $\theta \in \Omega$, where Ω is an interval set. Suppose that the statistic Y_1 is a complete and sufficient statistic for θ . Let $Z = u(X_1, X_2, \dots, X_n)$ be any other statistic (not a function of Y_1 alone). If the distribution of Z does not depend upon θ , then Z is independent of the sufficient statistic Y_1 .

In the discussion above, it is interesting to observe that if Y_1 is a sufficient statistic for θ , then the independence of Y_1 and Z implies that the distribution of Z does not depend upon θ whether $\{g_1(y_1; \theta) : \theta \in \Omega\}$ is or is not complete. Conversely, to prove the independence from the fact that $g_2(z)$ does not depend upon θ , we definitely need the completeness. Accordingly, if we are dealing with situations in which we know that family $\{g_1(y_1; \theta) : \theta \in \Omega\}$ is complete (such as a regular case of the exponential class), we can say that the statistic Z is independent of the sufficient statistic Y_1 if and only if the distribution of Z does not depend upon θ (i.e., Z is an ancillary statistic).

It should be remarked that the theorem (including the special formulation of it for regular cases of the exponential class) extends immediately to probability density functions that involve m parameters for which there exist m joint sufficient statistics. For example, let X_1, X_2, \dots, X_n be a random sample from a distribution having the pdf $f(x; \theta_1, \theta_2)$ that represents a regular case of the exponential class so that there are two joint complete sufficient statistics for θ_1 and θ_2 . Then any other statistic $Z = u(X_1, X_2, \dots, X_n)$ is independent of the joint complete sufficient statistics if and only if the distribution of Z does not depend upon θ_1 or θ_2 .

We present an example of the theorem that provides an alternative proof of the independence of \bar{X} and S^2 , the mean and the variance of a random sample of size n from a distribution that is $N(\mu, \sigma^2)$. This proof is given as if we were unaware that $(n-1)S^2/\sigma^2$ is $\chi^2(n-1)$, because that fact and the independence were established in Theorem 3.6.1.

Example 7.9.1. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution that is $N(\mu, \sigma^2)$. We know that the mean \bar{X} of the sample is, for every known σ^2 , a complete sufficient statistic for the parameter μ , $-\infty < \mu < \infty$. Consider the statistic

$$S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2,$$

which is location-invariant. Thus S^2 must have a distribution that does not depend upon μ ; and hence, by the theorem, S^2 and \bar{X} , the complete sufficient statistic for μ , are independent. ■

Example 7.9.2. Let X_1, X_2, \dots, X_n be a random sample of size n from the distribution having pdf

$$\begin{aligned} f(x; \theta) &= \exp\{-(x-\theta)\}, \quad \theta < x < \infty, \quad -\infty < \theta < \infty, \\ &= 0 \quad \text{elsewhere}. \end{aligned}$$

Here the pdf is of the form $f(x-\theta)$, where $f(w) = e^{-w}$, $0 < w < \infty$, zero elsewhere. Moreover, we know (Exercise 7.4.5) that the first order statistic $Y_1 = \min(X_i)$ is a

complete sufficient statistic for θ . Hence Y_1 must be independent of each location-invariant statistic $u(X_1, X_2, \dots, X_n)$, enjoying the property that

$$u(x_1 + d, x_2 + d, \dots, x_n + d) = u(x_1, x_2, \dots, x_n)$$

for all real d . Illustrations of such statistics are S^2 , the sample range, and

$$\frac{1}{n} \sum_{i=1}^n [X_i - \min(X_i)]. \quad \blacksquare$$

Example 7.9.3. Let X_1, X_2 denote a random sample of size $n = 2$ from a distribution with pdf

$$\begin{aligned} f(x; \theta) &= \frac{1}{\theta} e^{-x/\theta}, \quad 0 < x < \infty, \quad 0 < \theta < \infty, \\ &= 0 \quad \text{elsewhere.} \end{aligned}$$

The pdf is of the form $(1/\theta)f(x/\theta)$, where $f(w) = e^{-w}$, $0 < w < \infty$, zero elsewhere. We know that $Y_1 = X_1 + X_2$ is a complete sufficient statistic for θ . Hence, Y_1 is independent of every scale-invariant statistic $u(X_1, X_2)$ with the property $u(cx_1, cx_2) = u(x_1, x_2)$. Illustrations of these are X_1/X_2 and $X_1/(X_1 + X_2)$, statistics that have F - and beta distributions, respectively. ■

Example 7.9.4. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta_1, \theta_2)$, $-\infty < \theta_1 < \infty$, $0 < \theta_2 < \infty$. In Example 7.7.2 it was proved that the mean \bar{X} and the variance S^2 of the sample are joint complete sufficient statistics for θ_1 and θ_2 . Consider the statistic

$$Z = \frac{\sum_{i=1}^{n-1} (X_{i+1} - X_i)^2}{\sum_{i=1}^n (X_i - \bar{X})^2} = u(X_1, X_2, \dots, X_n),$$

which satisfies the property that $u(cx_1 + d, \dots, cx_n + d) = u(x_1, \dots, x_n)$. That is, the ancillary statistic Z is independent of both \bar{X} and S^2 . ■

In this section we have given several examples in which the complete sufficient statistics are independent of ancillary statistics. Thus, in those cases, the ancillary statistics provide no information about the parameters. However, if the sufficient statistics are not complete, the ancillary statistics could provide some information as the following example demonstrates.

Example 7.9.5. We refer back to Examples 7.8.1 and 7.8.2. There the first and n th order statistics, Y_1 and Y_n , were minimal sufficient statistics for θ , where the sample arose from an underlying distribution having pdf $(\frac{1}{2})I_{(\theta-1, \theta+1)}(x)$. Often $T_1 = (Y_1 + Y_n)/2$ is used as an estimator of θ , as it is a function of those sufficient statistics that is unbiased. Let us find a relationship between T_1 and the ancillary statistic $T_2 = Y_n - Y_1$.

The joint pdf of Y_1 and Y_n is

$$g(y_1, y_n; \theta) = n(n-1)(y_n - y_1)^{n-2}/2^n, \quad \theta - 1 < y_1 < y_n < \theta + 1,$$

zero elsewhere. Accordingly, the joint pdf of T_1 and T_2 is, since the absolute value of the Jacobian equals 1,

$$h(t_1, t_2; \theta) = n(n-1)t_2^{n-2}/2^n, \quad \theta - 1 + \frac{t_2}{2} < t_1 < \theta + 1 - \frac{t_2}{2}, \quad 0 < t_2 < 2,$$

zero elsewhere. Thus the pdf of T_2 is

$$h_2(t_2; \theta) = n(n-1)t_2^{n-2}(2-t_2)/2^n, \quad 0 < t_2 < 2,$$

zero elsewhere, which, of course, is free of θ as T_2 is an ancillary statistic. Thus, the conditional pdf of T_1 , given $T_2 = t_2$, is

$$h_{1|2}(t_1|t_2; \theta) = \frac{1}{2-t_2}, \quad \theta - 1 + \frac{t_2}{2} < t_1 < \theta + 1 - \frac{t_2}{2}, \quad 0 < t_2 < 2,$$

zero elsewhere. Note that this is uniform on the interval $(\theta - 1 + t_2/2, \theta + 1 - t_2/2)$; so the conditional mean and variance of T_1 are, respectively,

$$E(T_1|t_2) = \theta \quad \text{and} \quad \text{var}(T_1|t_2) = \frac{(2-t_2)^2}{12}.$$

Given $T_2 = t_2$, we know something about the conditional variance of T_1 . In particular, if that observed value of T_2 is large (close to 2), then that variance is small and we can place more reliance on the estimator T_1 . On the other hand, a small value of t_2 means that we have less confidence in T_1 as an estimator of θ . It is extremely interesting to note that this conditional variance does not depend upon the sample size n but only on the given value of $T_2 = t_2$. As the sample size increases, T_2 tends to become larger and, in those cases, T_1 has smaller conditional variance. ■

While Example 7.9.5 is a special one demonstrating mathematically that an ancillary statistic can provide some help in point estimation, this does actually happen in practice, too. For illustration, we know that if the sample size is large enough, then

$$T = \frac{\bar{X} - \mu}{S/\sqrt{n}}$$

has an approximate standard normal distribution. Of course, if the sample arises from a normal distribution, \bar{X} and S are independent and T has a t -distribution with $n-1$ degrees of freedom. Even if the sample arises from a symmetric distribution, \bar{X} and S are uncorrelated and T has an approximate t -distribution and certainly an approximate standard normal distribution with sample sizes around 30 or 40. On the other hand, if the sample arises from a highly skewed distribution (say to the right), then \bar{X} and S are highly correlated and the probability $P(-1.96 < T < 1.96)$ is not necessarily close to 0.95 unless the sample size is extremely large (certainly much greater than 30). Intuitively, one can understand why this correlation exists if

the underlying distribution is highly skewed to the right. While S has a distribution free of μ (and hence is an ancillary), a large value of S implies a large value of \bar{X} , since the underlying pdf is like the one depicted in Figure 7.9.1. Of course, a small value of \bar{X} (say less than the mode) requires a relatively small value of S . This means that unless n is extremely large, it is risky to say that

$$\bar{x} - \frac{1.96s}{\sqrt{n}}, \quad \bar{x} + \frac{1.96s}{\sqrt{n}}$$

provides an approximate 95% confidence interval with data from a very skewed distribution. As a matter of fact, the authors have seen situations in which this confidence coefficient is closer to 80%, rather than 95%, with sample sizes of 30 to 40.

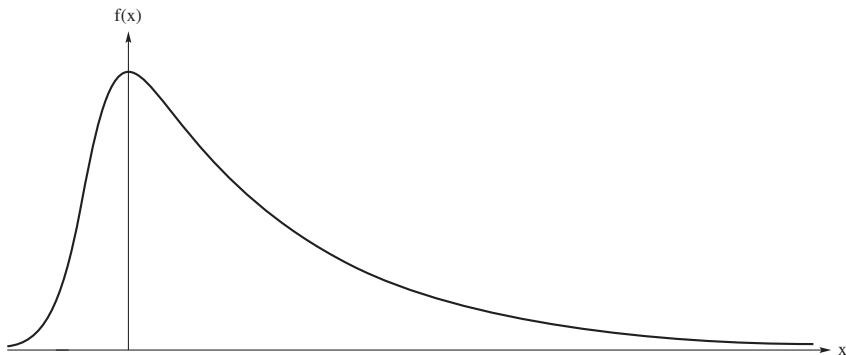

Figure 7.9.1: Graph of a right skewed distribution; see also Exercise 7.9.14.

EXERCISES

- 7.9.1.** Let $Y_1 < Y_2 < Y_3 < Y_4$ denote the order statistics of a random sample of size $n = 4$ from a distribution having pdf $f(x; \theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere, where $0 < \theta < \infty$. Argue that the complete sufficient statistic Y_4 for θ is independent of each of the statistics Y_1/Y_4 and $(Y_1 + Y_2)/(Y_3 + Y_4)$.

Hint: Show that the pdf is of the form $(1/\theta)f(x/\theta)$, where $f(w) = 1$, $0 < w < 1$, zero elsewhere.

- 7.9.2.** Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from a $N(\theta, \sigma^2)$, $-\infty < \theta < \infty$, distribution. Show that the distribution of $Z = Y_n - \bar{X}$ does not depend upon θ . Thus $\bar{Y} = \sum_1^n Y_i/n$, a complete sufficient statistic for θ is independent of Z .

- 7.9.3.** Let X_1, X_2, \dots, X_n be iid with the distribution $N(\theta, \sigma^2)$, $-\infty < \theta < \infty$. Prove that a necessary and sufficient condition that the statistics $Z = \sum_1^n a_i X_i$ and $Y = \sum_1^n X_i$, a complete sufficient statistic for θ , are independent is that $\sum_1^n a_i = 0$.

7.9.4. Let X and Y be random variables such that $E(X^k)$ and $E(Y^k) \neq 0$ exist for $k = 1, 2, 3, \dots$. If the ratio X/Y and its denominator Y are independent, prove that $E[(X/Y)^k] = E(X^k)/E(Y^k)$, $k = 1, 2, 3, \dots$

Hint: Write $E(X^k) = E[Y^k(X/Y)^k]$.

7.9.5. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample of size n from a distribution that has pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, $0 < \theta < \infty$, zero elsewhere. Show that the ratio $R = nY_1 / \sum_1^n Y_i$ and its denominator (a complete sufficient statistic for θ) are independent. Use the result of the preceding exercise to determine $E(R^k)$, $k = 1, 2, 3, \dots$

7.9.6. Let X_1, X_2, \dots, X_5 be iid with pdf $f(x) = e^{-x}$, $0 < x < \infty$, zero elsewhere. Show that $(X_1 + X_2)/(X_1 + X_2 + \dots + X_5)$ and its denominator are independent. *Hint:* The pdf $f(x)$ is a member of $\{f(x; \theta) : 0 < \theta < \infty\}$, where $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, zero elsewhere.

7.9.7. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from the normal distribution $N(\theta_1, \theta_2)$, $-\infty < \theta_1 < \infty$, $0 < \theta_2 < \infty$. Show that the joint complete sufficient statistics $\bar{X} = \bar{Y}$ and S^2 for θ_1 and θ_2 are independent of each of $(Y_n - \bar{Y})/S$ and $(Y_n - Y_1)/S$.

7.9.8. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from a distribution with the pdf

$$f(x; \theta_1, \theta_2) = \frac{1}{\theta_2} \exp\left(-\frac{x - \theta_1}{\theta_2}\right),$$

$\theta_1 < x < \infty$, zero elsewhere, where $-\infty < \theta_1 < \infty$, $0 < \theta_2 < \infty$. Show that the joint complete sufficient statistics Y_1 and $\bar{X} = \bar{Y}$ for the parameters θ_1 and θ_2 are independent of $(Y_2 - Y_1)/\sum_1^n (Y_i - Y_1)$.

7.9.9. Let X_1, X_2, \dots, X_5 be a random sample of size $n = 5$ from the normal distribution $N(0, \theta)$.

- (a) Argue that the ratio $R = (X_1^2 + X_2^2)/(X_1^2 + \dots + X_5^2)$ and its denominator $(X_1^2 + \dots + X_5^2)$ are independent.
- (b) Does $5R/2$ have an F -distribution with 2 and 5 degrees of freedom? Explain your answer.
- (c) Compute $E(R)$ using Exercise 7.9.4.

7.9.10. Referring to Example 7.9.5 of this section, determine c so that

$$P(-c < T_1 - \theta < c | T_2 = t_2) = 0.95.$$

Use this result to find a 95% confidence interval for θ , given $T_2 = t_2$; and note how its length is smaller when the range of t_2 is larger.

7.9.11. Show that $Y = |X|$ is a complete sufficient statistic for $\theta > 0$, where X has the pdf $f_X(x; \theta) = 1/(2\theta)$, for $-\theta < x < \theta$, zero elsewhere. Show that $Y = |X|$ and $Z = \text{sgn}(X)$ are independent.

7.9.12. Let $Y_1 < Y_2 < \dots < Y_n$ be the order statistics of a random sample from a $N(\theta, \sigma^2)$ distribution, where σ^2 is fixed but arbitrary. Then $\bar{Y} = \bar{X}$ is a complete sufficient statistic for θ . Consider another estimator T of θ , such as $T = (Y_i + Y_{n+1-i})/2$, for $i = 1, 2, \dots, [n/2]$, or T could be any weighted average of these latter statistics.

- (a) Argue that $T - \bar{X}$ and \bar{X} are independent random variables.
- (b) Show that $\text{Var}(T) = \text{Var}(\bar{X}) + \text{Var}(T - \bar{X})$.
- (c) Since we know $\text{Var}(\bar{X}) = \sigma^2/n$, it might be more efficient to estimate $\text{Var}(T)$ by estimating the $\text{Var}(T - \bar{X})$ by Monte Carlo methods rather than doing that with $\text{Var}(T)$ directly, because $\text{Var}(T) \geq \text{Var}(T - \bar{X})$. This is often called the *Monte Carlo Swindle*.

7.9.13. Suppose X_1, X_2, \dots, X_n is a random sample from a distribution with pdf $f(x; \theta) = (1/2)\theta^3 x^2 e^{-\theta x}$, $0 < x < \infty$, zero elsewhere, where $0 < \theta < \infty$:

- (a) Find the mle, $\hat{\theta}$, of θ . Is $\hat{\theta}$ unbiased?
Hint: Find the pdf of $Y = \sum_1^n X_i$ and then compute $E(\hat{\theta})$.
- (b) Argue that Y is a complete sufficient statistic for θ .
- (c) Find the MVUE of θ .
- (d) Show that X_1/Y and Y are independent.
- (e) What is the distribution of X_1/Y ?

7.9.14. The pdf depicted in Figure 7.9.1 is given by

$$f_{m_2}(x) = e^{-x}(1 + m_2^{-1}e^{-x})^{-(m_2+1)}, \quad -\infty < x < \infty, \quad (7.9.2)$$

where $m_2 > 0$ (the pdf graphed is for $m_2 = 0.1$). This is a member of a large family of pdfs, log F -family, which are useful in survival (lifetime) analysis; see Chapter 3 of Hettmansperger and McKean (2011).

- (a) Let W be a random variable with pdf (7.9.2). Show that $W = \log Y$, where Y has an F -distribution with 2 and $2m_2$ degrees of freedom.
- (b) Show that the pdf becomes the logistic (6.1.8) if $m_2 = 1$.
- (c) Consider the location model where

$$X_i = \theta + W_i \quad i = 1, \dots, n,$$

where W_1, \dots, W_n are iid with pdf (7.9.2). Similar to the logistic location model, the order statistics are minimal sufficient for this model. Show, similar to Example 6.1.2, that the mle of θ exists.

Chapter 8

Optimal Tests of Hypotheses

8.1 Most Powerful Tests

In Section 4.5, we introduced the concept of hypotheses testing and followed it with the introduction of likelihood ratio tests in Chapter 6. In this chapter, we discuss certain best tests.

For convenience to the reader, in the next several paragraphs we quickly review concepts of testing that were presented in Section 4.5. We are interested in a random variable X that has pdf or pmf $f(x; \theta)$, where $\theta \in \Omega$. We assume that $\theta \in \omega_0$ or $\theta \in \omega_1$, where ω_0 and ω_1 are disjoint subsets of Ω and $\omega_0 \cup \omega_1 = \Omega$. We label the hypotheses as

$$H_0 : \theta \in \omega_0 \text{ versus } H_1 : \theta \in \omega_1. \quad (8.1.1)$$

The hypothesis H_0 is referred to as the **null hypothesis**, while H_1 is referred to as the **alternative hypothesis**. The test of H_0 versus H_1 is based on a sample X_1, \dots, X_n from the distribution of X . In this chapter, we often use the vector $\mathbf{X}' = (X_1, \dots, X_n)$ to denote the random sample and $\mathbf{x}' = (x_1, \dots, x_n)$ to denote the values of the sample. Let \mathcal{S} denote the support of the random sample $\mathbf{X}' = (X_1, \dots, X_n)$.

A **test** of H_0 versus H_1 is based on a subset C of \mathcal{S} . This set C is called the **critical region** and its corresponding decision rule is

$$\begin{aligned} \text{Reject } H_0 \text{ (Accept } H_1) &\quad \text{if } \mathbf{X} \in C \\ \text{Retain } H_0 \text{ (Reject } H_1) &\quad \text{if } \mathbf{X} \in C^c. \end{aligned} \quad (8.1.2)$$

Note that a test is defined by its critical region. Conversely, a critical region defines a test.

Recall that the 2×2 decision table, Table 4.5.1, summarizes the results of the hypothesis test in terms of the true state of nature. Besides the correct decisions, two errors can occur. A **Type I** error occurs if H_0 is rejected when it is true, while a **Type II** error occurs if H_0 is accepted when H_1 is true. The **size** or **significance**

level of the test is the probability of a Type I error; i.e.,

$$\alpha = \max_{\theta \in \omega_0} P_\theta(\mathbf{X} \in C). \quad (8.1.3)$$

Note that $P_\theta(\mathbf{X} \in C)$ should be read as the probability that $\mathbf{X} \in C$ when θ is the true parameter. Subject to tests having size α , we select tests that minimize Type II error or equivalently maximize the probability of rejecting H_0 when $\theta \in \omega_1$. Recall that the **power function** of a test is given by

$$\gamma_C(\theta) = P_\theta(\mathbf{X} \in C); \quad \theta \in \omega_1. \quad (8.1.4)$$

In Chapter 4, we gave examples of tests of hypotheses, while in Sections 6.3 and 6.4, we discussed tests based on maximum likelihood theory. In this chapter, we want to construct best tests for certain situations.

We begin with testing a simple hypothesis H_0 against a simple alternative H_1 . Let $f(x; \theta)$ denote the pdf or pmf of a random variable X , where $\theta \in \Omega = \{\theta', \theta''\}$. Let $\omega_0 = \{\theta'\}$ and $\omega_1 = \{\theta''\}$. Let $\mathbf{X}' = (X_1, \dots, X_n)$ be a random sample from the distribution of X . We now define a best critical region (and hence a best test) for testing the simple hypothesis H_0 against the alternative simple hypothesis H_1 .

Definition 8.1.1. Let C denote a subset of the sample space. Then we say that C is a **best critical region** of size α for testing the simple hypothesis $H_0 : \theta = \theta'$ against the alternative simple hypothesis $H_1 : \theta = \theta''$ if

(a) $P_{\theta'}[\mathbf{X} \in C] = \alpha$.

(b) And for every subset A of the sample space,

$$P_{\theta'}[\mathbf{X} \in A] = \alpha \Rightarrow P_{\theta''}[\mathbf{X} \in C] \geq P_{\theta''}[\mathbf{X} \in A].$$

This definition states, in effect, the following: In general, there is a multiplicity of subsets A of the sample space such that $P_{\theta'}[\mathbf{X} \in A] = \alpha$. Suppose that there is one of these subsets, say C , such that when H_1 is true, the power of the test associated with C is at least as great as the power of the test associated with every other A . Then C is defined as a best critical region of size α for testing H_0 against H_1 .

As Theorem 8.1.1 shows, there is a best test for this simple versus simple case. But first, we offer a simple example examining this definition in some detail.

Example 8.1.1. Consider the one random variable X that has a binomial distribution with $n = 5$ and $p = \theta$. Let $f(x; \theta)$ denote the pmf of X and let $H_0 : \theta = \frac{1}{2}$ and $H_1 : \theta = \frac{3}{4}$. The following tabulation gives, at points of positive probability density, the values of $f(x; \frac{1}{2})$, $f(x; \frac{3}{4})$, and the ratio $f(x; \frac{1}{2})/f(x; \frac{3}{4})$.

x	0	1	2
$f(x; 1/2)$	1/32	5/32	10/32
$f(x; 3/4)$	1/1024	15/1024	90/1024
$f(x; 1/2)/f(x; 3/4)$	32/1	32/3	32/9
x	3	4	5
$f(x; 1/2)$	10/32	5/32	1/32
$f(x; 3/4)$	270/1024	405/1024	243/1024
$f(x; 1/2)/f(x; 3/4)$	32/27	32/81	32/243

We shall use one random value of X to test the simple hypothesis $H_0 : \theta = \frac{1}{2}$ against the alternative simple hypothesis $H_1 : \theta = \frac{3}{4}$, and we shall first assign the significance level of the test to be $\alpha = \frac{1}{32}$. We seek a best critical region of size $\alpha = \frac{1}{32}$. If $A_1 = \{x : x = 0\}$ or $A_2 = \{x : x = 5\}$, then $P_{\{\theta=1/2\}}(X \in A_1) = P_{\{\theta=1/2\}}(X \in A_2) = \frac{1}{32}$ and there is no other subset A_3 of the space $\{x : x = 0, 1, 2, 3, 4, 5\}$ such that $P_{\{\theta=1/2\}}(X \in A_3) = \frac{1}{32}$. Then either A_1 or A_2 is the best critical region C of size $\alpha = \frac{1}{32}$ for testing H_0 against H_1 . We note that $P_{\{\theta=1/2\}}(X \in A_1) = \frac{1}{32}$ and $P_{\{\theta=3/4\}}(X \in A_1) = \frac{1}{1024}$. Thus, if the set A_1 is used as a critical region of size $\alpha = \frac{1}{32}$, we have the intolerable situation that the probability of rejecting H_0 when H_1 is true (H_0 is false) is much less than the probability of rejecting H_0 when H_0 is true.

On the other hand, if the set A_2 is used as a critical region, then $P_{\{\theta=1/2\}}(X \in A_2) = \frac{1}{32}$ and $P_{\{\theta=3/4\}}(X \in A_2) = \frac{243}{1024}$. That is, the probability of rejecting H_0 when H_1 is true is much greater than the probability of rejecting H_0 when H_0 is true. Certainly, this is a more desirable state of affairs, and actually A_2 is the best critical region of size $\alpha = \frac{1}{32}$. The latter statement follows from the fact that when H_0 is true, there are but two subsets, A_1 and A_2 , of the sample space, each of whose probability measure is $\frac{1}{32}$ and the fact that

$$\frac{243}{1024} = P_{\{\theta=3/4\}}(X \in A_2) > P_{\{\theta=3/4\}}(X \in A_1) = \frac{1}{1024}.$$

It should be noted in this problem that the best critical region $C = A_2$ of size $\alpha = \frac{1}{32}$ is found by including in C the point (or points) at which $f(x; \frac{1}{2})$ is small in comparison with $f(x; \frac{3}{4})$. This is seen to be true once it is observed that the ratio $f(x; \frac{1}{2})/f(x; \frac{3}{4})$ is a minimum at $x = 5$. Accordingly, the ratio $f(x; \frac{1}{2})/f(x; \frac{3}{4})$, that is given in the last line of the above tabulation, provides us with a precise tool by which to find a best critical region C for certain given values of α . To illustrate this, take $\alpha = \frac{6}{32}$. When H_0 is true, each of the subsets $\{x : x = 0, 1\}$, $\{x : x = 0, 4\}$, $\{x : x = 1, 5\}$, $\{x : x = 4, 5\}$ has probability measure $\frac{6}{32}$. By direct computation it is found that the best critical region of this size is $\{x : x = 4, 5\}$. This reflects the fact that the ratio $f(x; \frac{1}{2})/f(x; \frac{3}{4})$ has its two smallest values for $x = 4$ and $x = 5$. The power of this test, which has $\alpha = \frac{6}{32}$, is

$$P_{\{\theta=3/4\}}(X = 4, 5) = \frac{405}{1024} + \frac{243}{1024} = \frac{648}{1024}. \quad \blacksquare$$

The preceding example should make the following theorem, due to Neyman and Pearson, easier to understand. It is an important theorem because it provides a systematic method of determining a best critical region.

Theorem 8.1.1. Neyman–Pearson Theorem. Let X_1, X_2, \dots, X_n , where n is a fixed positive integer, denote a random sample from a distribution that has pdf or pmf $f(x; \theta)$. Then the likelihood of X_1, X_2, \dots, X_n is

$$L(\theta; \mathbf{x}) = \prod_{i=1}^n f(x_i; \theta), \quad \text{for } \mathbf{x}' = (x_1, \dots, x_n).$$

Let θ' and θ'' be distinct fixed values of θ so that $\Omega = \{\theta : \theta = \theta', \theta''\}$, and let k be a positive number. Let C be a subset of the sample space such that

- (a) $\frac{L(\theta'; \mathbf{x})}{L(\theta''; \mathbf{x})} \leq k$, for each point $\mathbf{x} \in C$.
- (b) $\frac{L(\theta'; \mathbf{x})}{L(\theta''; \mathbf{x})} \geq k$, for each point $\mathbf{x} \in C^c$.
- (c) $\alpha = P_{H_0}[\mathbf{X} \in C]$.

Then C is a best critical region of size α for testing the simple hypothesis $H_0 : \theta = \theta'$ against the alternative simple hypothesis $H_1 : \theta = \theta''$.

Proof: We shall give the proof when the random variables are of the continuous type. If C is the only critical region of size α , the theorem is proved. If there is another critical region of size α , denote it by A . For convenience, we shall let $\int_R L(\theta; x_1, \dots, x_n) dx_1 \cdots dx_n$ be denoted by $\int_R L(\theta)$. In this notation we wish to show that

$$\int_C L(\theta'') - \int_A L(\theta'') \geq 0.$$

Since C is the union of the disjoint sets $C \cap A$ and $C \cap A^c$ and A is the union of the disjoint sets $A \cap C$ and $A \cap C^c$, we have

$$\begin{aligned} \int_C L(\theta'') - \int_A L(\theta'') &= \int_{C \cap A} L(\theta'') + \int_{C \cap A^c} L(\theta'') - \int_{A \cap C} L(\theta'') - \int_{A \cap C^c} L(\theta'') \\ &= \int_{C \cap A^c} L(\theta'') - \int_{A \cap C^c} L(\theta''). \end{aligned} \quad (8.1.5)$$

However, by the hypothesis of the theorem, $L(\theta'') \geq (1/k)L(\theta')$ at each point of C , and hence at each point of $C \cap A^c$; thus,

$$\int_{C \cap A^c} L(\theta'') \geq \frac{1}{k} \int_{C \cap A^c} L(\theta').$$

But $L(\theta'') \leq (1/k)L(\theta')$ at each point of C^c , and hence at each point of $A \cap C^c$; accordingly,

$$\int_{A \cap C^c} L(\theta'') \leq \frac{1}{k} \int_{A \cap C^c} L(\theta').$$

These inequalities imply that

$$\int_{C \cap A^c} L(\theta'') - \int_{A \cap C^c} L(\theta'') \geq \frac{1}{k} \int_{C \cap A^c} L(\theta') - \frac{1}{k} \int_{A \cap C^c} L(\theta');$$

and, from Equation (8.1.5), we obtain

$$\int_C L(\theta'') - \int_A L(\theta'') \geq \frac{1}{k} \left[\int_{C \cap A^c} L(\theta') - \int_{A \cap C^c} L(\theta') \right]. \quad (8.1.6)$$

However,

$$\begin{aligned} \int_{C \cap A^c} L(\theta') - \int_{A \cap C^c} L(\theta') &= \int_{C \cap A^c} L(\theta') + \int_{C \cap A} L(\theta') \\ &\quad - \int_{A \cap C} L(\theta') - \int_{A \cap C^c} L(\theta') \\ &= \int_C L(\theta') - \int_A L(\theta') = \alpha - \alpha = 0. \end{aligned}$$

If this result is substituted in inequality (8.1.6), we obtain the desired result,

$$\int_C L(\theta'') - \int_A L(\theta'') \geq 0.$$

If the random variables are of the discrete type, the proof is the same with integration replaced by summation. ■

Remark 8.1.1. As stated in the theorem, conditions (a), (b), and (c) are sufficient ones for region C to be a best critical region of size α . However, they are also necessary. We discuss this briefly. Suppose there is a region A of size α that does not satisfy (a) and (b) and that is as powerful at $\theta = \theta''$ as C , which satisfies (a), (b), and (c). Then expression (8.1.5) would be zero, since the power at θ'' using A is equal to that using C . It can be proved that to have expression (8.1.5) equal zero, A must be of the same form as C . As a matter of fact, in the continuous case, A and C would essentially be the same region; that is, they could differ only by a set having probability zero. However, in the discrete case, if $P_{H_0}[L(\theta') = kL(\theta'')]$ is positive, A and C could be different sets, but each would necessarily enjoy conditions (a), (b), and (c) to be a best critical region of size α . ■

It would seem that a test should have the property that its power should never fall below its significance level; otherwise, the probability of falsely rejecting H_0 (level) is higher than the probability of correctly rejecting H_0 (power). We say a test having this property is **unbiased**, which we now formally define:

Definition 8.1.2. Let X be a random variable which has pdf or pmf $f(x; \theta)$, where $\theta \in \Omega$. Consider the hypotheses given in expression (8.1.1). Let $\mathbf{X}' = (X_1, \dots, X_n)$ denote a random sample on X . Consider a test with critical region C and level α . We say that this test is **unbiased** if

$$P_\theta(\mathbf{X} \in C) \geq \alpha,$$

for all $\theta \in \omega_1$.

As the next corollary shows, the best test given in Theorem 8.1.1 is an unbiased test.

Corollary 8.1.1. *As in Theorem 8.1.1, let C be the critical region of the best test of $H_0 : \theta = \theta'$ versus $H_1 : \theta = \theta''$. Suppose the significance level of the test is α . Let $\gamma_C(\theta'') = P_{\theta''}[\mathbf{X} \in C]$ denote the power of the test. Then $\alpha \leq \gamma_C(\theta'')$.*

Proof: Consider the “unreasonable” test in which the data are ignored, but a Bernoulli trial is performed which has probability α of success. If the trial ends in success, we reject H_0 . The level of this test is α . Because the power of a test is the probability of rejecting H_0 when H_1 is true, the power of this unreasonable test is α also. But C is the best critical region of size α and thus has power greater than or equal to the power of the unreasonable test. That is, $\gamma_C(\theta'') \geq \alpha$, which is the desired result. ■

Another aspect of Theorem 8.1.1 to be emphasized is that if we take C to be the set of all points \mathbf{x} which satisfy

$$\frac{L(\theta'; \mathbf{x})}{L(\theta''; \mathbf{x})} \leq k, \quad k > 0,$$

then, in accordance with the theorem, C is a best critical region. This inequality can frequently be expressed in one of the forms (where c_1 and c_2 are constants)

$$u_1(\mathbf{x}; \theta', \theta'') \leq c_1$$

or

$$u_2(\mathbf{x}; \theta', \theta'') \geq c_2.$$

Suppose that it is the first form, $u_1 \leq c_1$. Since θ' and θ'' are given constants, $u_1(\mathbf{X}; \theta', \theta'')$ is a statistic; and if the pdf or pmf of this statistic can be found when H_0 is true, then the significance level of the test of H_0 against H_1 can be determined from this distribution. That is,

$$\alpha = P_{H_0}[u_1(\mathbf{X}; \theta', \theta'') \leq c_1].$$

Moreover, the test may be based on this statistic; for if the observed vector value of \mathbf{X} is \mathbf{x} , we reject H_0 (accept H_1) if $u_1(\mathbf{x}) \leq c_1$.

A positive number k determines a best critical region C whose size is $\alpha = P_{H_0}[\mathbf{X} \in C]$ for that particular k . It may be that this value of α is unsuitable for the purpose at hand; that is, it is too large or too small. However, if there is a statistic $u_1(\mathbf{X})$ as in the preceding paragraph, whose pdf or pmf can be determined when H_0 is true, we need not experiment with various values of k to obtain a desirable significance level. For if the distribution of the statistic is known, or can be found, we may determine c_1 such that $P_{H_0}[u_1(\mathbf{X}) \leq c_1]$ is a desirable significance level.

An illustrative example follows.

Example 8.1.2. Let $\mathbf{X}' = (X_1, \dots, X_n)$ denote a random sample from the distribution that has the pdf

$$f(x; \theta) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{(x-\theta)^2}{2}\right), \quad -\infty < x < \infty.$$

It is desired to test the simple hypothesis $H_0 : \theta = \theta' = 0$ against the alternative simple hypothesis $H_1 : \theta = \theta'' = 1$. Now

$$\begin{aligned} \frac{L(\theta'; \mathbf{x})}{L(\theta''; \mathbf{x})} &= \frac{(1/\sqrt{2\pi})^n \exp\left[-\sum_1^n x_i^2/2\right]}{(1/\sqrt{2\pi})^n \exp\left[-\sum_1^n (x_i - 1)^2/2\right]} \\ &= \exp\left(-\sum_1^n x_i + \frac{n}{2}\right). \end{aligned}$$

If $k > 0$, the set of all points (x_1, x_2, \dots, x_n) such that

$$\exp\left(-\sum_1^n x_i + \frac{n}{2}\right) \leq k$$

is a best critical region. This inequality holds if and only if

$$-\sum_1^n x_i + \frac{n}{2} \leq \log k$$

or, equivalently,

$$\sum_1^n x_i \geq \frac{n}{2} - \log k = c.$$

In this case, a best critical region is the set $C = \{(x_1, x_2, \dots, x_n) : \sum_1^n x_i \geq c\}$, where c is a constant that can be determined so that the size of the critical region is a desired number α . The event $\sum_1^n X_i \geq c$ is equivalent to the event $\bar{X} \geq c/n = c_1$, for example, so the test may be based upon the statistic \bar{X} . If H_0 is true, that is, $\theta = \theta' = 0$, then \bar{X} has a distribution that is $N(0, 1/n)$. Given the significance level α , the number c_1 is computed in R as $c_1 = \text{qnorm}(1 - \alpha, 0, 1/\sqrt{n})$; hence, $P_{H_0}(\bar{X} \geq c_1) = \alpha$. So, if the experimental values of X_1, X_2, \dots, X_n were, respectively, x_1, x_2, \dots, x_n , we would compute $\bar{x} = \sum_1^n x_i/n$. If $\bar{x} \geq c_1$, the simple hypothesis $H_0 : \theta = \theta' = 0$ would be rejected at the significance level α ; if $\bar{x} < c_1$, the hypothesis H_0 would be accepted. The probability of rejecting H_0 when H_0 is true is α the level of significance. The probability of rejecting H_0 , when H_0 is false, is the value of the power of the test at $\theta = \theta'' = 1$, which is,

$$P_{H_1}(\bar{X} \geq c_1) = \int_{c_1}^{\infty} \frac{1}{\sqrt{2\pi}\sqrt{1/n}} \exp\left[-\frac{(\bar{x}-1)^2}{2(1/n)}\right] d\bar{x}. \quad (8.1.7)$$

For example, if $n = 25$ and α is 0.05, $c_1 = \text{qnorm}(0.95, 0, 1/5) = 0.329$, using R. Hence, the power of the test to detect $\theta = 1$, given in expression (8.1.7), is computed by $1 - \text{pnorm}(0.329, 1, 1/5) = 0.9996$. ■

There is another aspect of this theorem that warrants special mention. It has to do with the number of parameters that appear in the pdf. Our notation suggests that there is but one parameter. However, a careful review of the proof reveals that nowhere was this needed or assumed. The pdf or pmf may depend upon any finite number of parameters. What is essential is that the hypothesis H_0 and the alternative hypothesis H_1 be simple, namely, that they completely specify the distributions. With this in mind, we see that the simple hypotheses H_0 and H_1 do not need to be hypotheses about the parameters of a distribution, nor, as a matter of fact, do the random variables X_1, X_2, \dots, X_n need to be independent. That is, if H_0 is the simple hypothesis that the joint pdf or pmf is $g(x_1, x_2, \dots, x_n)$, and if H_1 is the alternative simple hypothesis that the joint pdf or pmf is $h(x_1, x_2, \dots, x_n)$, then C is a best critical region of size α for testing H_0 against H_1 if, for $k > 0$,

1. $\frac{g(x_1, x_2, \dots, x_n)}{h(x_1, x_2, \dots, x_n)} \leq k$ for $(x_1, x_2, \dots, x_n) \in C$.
2. $\frac{g(x_1, x_2, \dots, x_n)}{h(x_1, x_2, \dots, x_n)} \geq k$ for $(x_1, x_2, \dots, x_n) \in C^c$.
3. $\alpha = P_{H_0}[(X_1, X_2, \dots, X_n) \in C]$.

Consider the following example.

Example 8.1.3. Let X_1, \dots, X_n denote a random sample on X that has pmf $f(x)$ with support $\{0, 1, 2, \dots\}$. It is desired to test the simple hypothesis

$$H_0 : f(x) = \begin{cases} \frac{e^{-1}}{x!} & x = 0, 1, 2, \dots \\ 0 & \text{elsewhere,} \end{cases}$$

against the alternative simple hypothesis

$$H_1 : f(x) = \begin{cases} \left(\frac{1}{2}\right)^{x+1} & x = 0, 1, 2, \dots \\ 0 & \text{elsewhere.} \end{cases}$$

That is, we want to test whether X has a Poisson distribution with mean $\lambda = 1$ versus X has a geometric distribution with $p = 1/2$. Here

$$\begin{aligned} \frac{g(x_1, \dots, x_n)}{h(x_1, \dots, x_n)} &= \frac{e^{-n}/(x_1!x_2!\cdots x_n!)}{\left(\frac{1}{2}\right)^n \left(\frac{1}{2}\right)^{x_1+x_2+\cdots+x_n}} \\ &= \frac{(2e^{-1})^n 2^{\sum x_i}}{\prod_1^n (x_i!)}. \end{aligned}$$

If $k > 0$, the set of points (x_1, x_2, \dots, x_n) such that

$$\left(\sum_1^n x_i \right) \log 2 - \log \left[\prod_1^n (x_i!) \right] \leq \log k - n \log(2e^{-1}) = c$$

is a best critical region C . Consider the case of $k = 1$ and $n = 1$. The preceding inequality may be written $2^{x_1}/x_1! \leq e/2$. This inequality is satisfied by all points in the set $C = \{x_1 : x_1 = 0, 3, 4, 5, \dots\}$. Using R, the level of significance is

$$P_{H_0}(X_1 \in C) = 1 - P_{H_0}(X_1 = 1, 2) = 1 - \text{dpois}(1, 1) - \text{dpois}(2, 1) = 0.4482.$$

The power of the test to detect H_1 is computed as

$$P_{H_1}(X_1 \in C) = 1 - P_{H_1}(X_1 = 1, 2) = 1 - (\frac{1}{4} + \frac{1}{8}) = 0.625. \blacksquare$$

Note that these results are consistent with Corollary 8.1.1.

Remark 8.1.2. In the notation of this section, say C is a critical region such that

$$\alpha = \int_C L(\theta') \quad \text{and} \quad \beta = \int_{C^c} L(\theta''),$$

where α and β equal the respective probabilities of the Type I and Type II errors associated with C . Let d_1 and d_2 be two given positive constants. Consider a certain linear function of α and β , namely,

$$\begin{aligned} d_1 \int_C L(\theta') + d_2 \int_{C^c} L(\theta'') &= d_1 \int_C L(\theta') + d_2 \left[1 - \int_C L(\theta'') \right] \\ &= d_2 + \int_C [d_1 L(\theta') - d_2 L(\theta'')]. \end{aligned}$$

If we wished to minimize this expression, we would select C to be the set of all (x_1, x_2, \dots, x_n) such that

$$d_1 L(\theta') - d_2 L(\theta'') < 0$$

or, equivalently,

$$\frac{L(\theta')}{L(\theta'')} < \frac{d_2}{d_1}, \quad \text{for all } (x_1, x_2, \dots, x_n) \in C,$$

which according to the Neyman–Pearson theorem provides a best critical region with $k = d_2/d_1$. That is, this critical region C is one that minimizes $d_1\alpha + d_2\beta$. There could be others, including points on which $L(\theta')/L(\theta'') = d_2/d_1$, but these would still be best critical regions according to the Neyman–Pearson theorem. ■

EXERCISES

8.1.1. In Example 8.1.2 of this section, let the simple hypotheses read $H_0 : \theta = \theta' = 0$ and $H_1 : \theta = \theta'' = -1$. Show that the best test of H_0 against H_1 may be carried out by use of the statistic \bar{X} , and that if $n = 25$ and $\alpha = 0.05$, the power of the test is 0.9996 when H_1 is true.

8.1.2. Let the random variable X have the pdf $f(x; \theta) = (1/\theta)e^{-x/\theta}$, $0 < x < \infty$, zero elsewhere. Consider the simple hypothesis $H_0 : \theta = \theta' = 2$ and the alternative hypothesis $H_1 : \theta = \theta'' = 4$. Let X_1, X_2 denote a random sample of size 2 from this distribution. Show that the best test of H_0 against H_1 may be carried out by use of the statistic $X_1 + X_2$.

8.1.3. Repeat Exercise 8.1.2 when $H_1 : \theta = \theta'' = 6$. Generalize this for every $\theta'' > 2$.

8.1.4. Let X_1, X_2, \dots, X_{10} be a random sample of size 10 from a normal distribution $N(0, \sigma^2)$. Find a best critical region of size $\alpha = 0.05$ for testing $H_0 : \sigma^2 = 1$ against $H_1 : \sigma^2 = 2$. Is this a best critical region of size 0.05 for testing $H_0 : \sigma^2 = 1$ against $H_1 : \sigma^2 = 4$? Against $H_1 : \sigma^2 = \sigma_1^2 > 1$?

8.1.5. If X_1, X_2, \dots, X_n is a random sample from a distribution having pdf of the form $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, zero elsewhere, show that a best critical region for testing $H_0 : \theta = 1$ against $H_1 : \theta = 2$ is $C = \{(x_1, x_2, \dots, x_n) : c \leq \prod_{i=1}^n x_i\}$.

8.1.6. Let X_1, X_2, \dots, X_{10} be a random sample from a distribution that is $N(\theta_1, \theta_2)$. Find a best test of the simple hypothesis $H_0 : \theta_1 = \theta'_1 = 0$, $\theta_2 = \theta'_2 = 1$ against the alternative simple hypothesis $H_1 : \theta_1 = \theta''_1 = 1$, $\theta_2 = \theta''_2 = 4$.

8.1.7. Let X_1, X_2, \dots, X_n denote a random sample from a normal distribution $N(\theta, 100)$. Show that $C = \{(x_1, x_2, \dots, x_n) : c \leq \bar{x} = \sum_1^n x_i/n\}$ is a best critical region for testing $H_0 : \theta = 75$ against $H_1 : \theta = 78$. Find n and c so that

$$P_{H_0}[(X_1, X_2, \dots, X_n) \in C] = P_{H_0}(\bar{X} \geq c) = 0.05$$

and

$$P_{H_1}[(X_1, X_2, \dots, X_n) \in C] = P_{H_1}(\bar{X} \geq c) = 0.90,$$

approximately.

8.1.8. If X_1, X_2, \dots, X_n is a random sample from a beta distribution with parameters $\alpha = \beta = \theta > 0$, find a best critical region for testing $H_0 : \theta = 1$ against $H_1 : \theta = 2$.

8.1.9. Let X_1, X_2, \dots, X_n be iid with pmf $f(x; p) = p^x(1-p)^{1-x}$, $x = 0, 1$, zero elsewhere. Show that $C = \{(x_1, \dots, x_n) : \sum_1^n x_i \leq c\}$ is a best critical region for testing $H_0 : p = \frac{1}{2}$ against $H_1 : p = \frac{1}{3}$. Use the Central Limit Theorem to find n and c so that approximately $P_{H_0}(\sum_1^n X_i \leq c) = 0.10$ and $P_{H_1}(\sum_1^n X_i \leq c) = 0.80$.

8.1.10. Let X_1, X_2, \dots, X_{10} denote a random sample of size 10 from a Poisson distribution with mean θ . Show that the critical region C defined by $\sum_1^{10} x_i \geq 3$ is a best critical region for testing $H_0 : \theta = 0.1$ against $H_1 : \theta = 0.5$. Determine, for this test, the significance level α and the power at $\theta = 0.5$. Use the R function `ppois`.

8.2 Uniformly Most Powerful Tests

This section takes up the problem of a test of a simple hypothesis H_0 against an alternative composite hypothesis H_1 . We begin with an example.

Example 8.2.1. Consider the pdf

$$f(x; \theta) = \begin{cases} \frac{1}{\theta} e^{-x/\theta} & 0 < x < \infty \\ 0 & \text{elsewhere} \end{cases}$$

of Exercises 8.1.2 and 8.1.3. It is desired to test the simple hypothesis $H_0 : \theta = 2$ against the alternative composite hypothesis $H_1 : \theta > 2$. Thus $\Omega = \{\theta : \theta \geq 2\}$. A random sample, X_1, X_2 , of size $n = 2$ is used, and the critical region is $C = \{(x_1, x_2) : 9.5 \leq x_1 + x_2 < \infty\}$. It was shown in the exercises cited that the significance level of the test is approximately 0.05 and the power of the test when $\theta = 4$ is approximately 0.31. The power function $\gamma(\theta)$ of the test for all $\theta \geq 2$ is

$$\begin{aligned} \gamma(\theta) &= 1 - \int_0^{9.5} \int_0^{9.5-x_2} \frac{1}{\theta^2} \exp\left(-\frac{x_1+x_2}{\theta}\right) dx_1 dx_2 \\ &= \left(\frac{\theta+9.5}{\theta}\right) e^{-9.5/\theta}, \quad 2 \leq \theta. \end{aligned}$$

For example, $\gamma(2) = 0.05$, $\gamma(4) = 0.31$, and $\gamma(9.5) = 2/e \approx 0.74$. It is shown (Exercise 8.1.3) that the set $C = \{(x_1, x_2) : 9.5 \leq x_1 + x_2 < \infty\}$ is a best critical region of size 0.05 for testing the simple hypothesis $H_0 : \theta = 2$ against each simple hypothesis in the composite hypothesis $H_1 : \theta > 2$. ■

The preceding example affords an illustration of a test of a simple hypothesis H_0 that is a best test of H_0 against every simple hypothesis in the alternative composite hypothesis H_1 . We now define a critical region, when it exists, which is a best critical region for testing a simple hypothesis H_0 against an alternative composite hypothesis H_1 . It seems desirable that this critical region should be a best critical region for testing H_0 against each simple hypothesis in H_1 . That is, the power function of the test that corresponds to this critical region should be at least as great as the power function of any other test with the same significance level for every simple hypothesis in H_1 .

Definition 8.2.1. *The critical region C is a **uniformly most powerful (UMP) critical region** of size α for testing the simple hypothesis H_0 against an alternative composite hypothesis H_1 if the set C is a best critical region of size α for testing H_0 against each simple hypothesis in H_1 . A test defined by this critical region C is called a **uniformly most powerful (UMP) test**, with significance level α , for testing the simple hypothesis H_0 against the alternative composite hypothesis H_1 .*

As will be seen presently, uniformly most powerful tests do not always exist. However, when they do exist, the Neyman–Pearson theorem provides a technique for finding them. Some illustrative examples are given here.

Example 8.2.2. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(0, \theta)$, where the variance θ is an unknown positive number. It will be shown that there exists a uniformly most powerful test with significance level α for testing the simple hypothesis $H_0 : \theta = \theta'$, where θ' is a fixed positive number, against the alternative composite hypothesis $H_1 : \theta > \theta'$. Thus $\Omega = \{\theta : \theta \geq \theta'\}$. The joint pdf of X_1, X_2, \dots, X_n is

$$L(\theta; x_1, x_2, \dots, x_n) = \left(\frac{1}{2\pi\theta} \right)^{n/2} \exp \left\{ -\frac{1}{2\theta} \sum_{i=1}^n x_i^2 \right\}.$$

Let θ'' represent a number greater than θ' , and let k denote a positive number. Let C be the set of points where

$$\frac{L(\theta'; x_1, x_2, \dots, x_n)}{L(\theta''; x_1, x_2, \dots, x_n)} \leq k,$$

that is, the set of points where

$$\left(\frac{\theta''}{\theta'} \right)^{n/2} \exp \left[- \left(\frac{\theta'' - \theta'}{2\theta'\theta''} \right) \sum_{i=1}^n x_i^2 \right] \leq k$$

or, equivalently,

$$\sum_{i=1}^n x_i^2 \geq \frac{2\theta'\theta''}{\theta'' - \theta'} \left[\frac{n}{2} \log \left(\frac{\theta''}{\theta'} \right) - \log k \right] = c.$$

The set $C = \{(x_1, x_2, \dots, x_n) : \sum_{i=1}^n x_i^2 \geq c\}$ is then a best critical region for testing the simple hypothesis $H_0 : \theta = \theta'$ against the simple hypothesis $\theta = \theta''$. It remains to determine c , so that this critical region has the desired size α . If H_0 is true, the random variable $\sum_{i=1}^n X_i^2 / \theta'$ has a chi-square distribution with n degrees of freedom. Since $\alpha = P_{\theta'}(\sum_{i=1}^n X_i^2 / \theta' \geq c/\theta')$, c/θ' may be computed, for example, by the R code `qchisq(1 - alpha, n)`. Then $C = \{(x_1, x_2, \dots, x_n) : \sum_{i=1}^n x_i^2 \geq c\}$ is a best critical region of size α for testing $H_0 : \theta = \theta'$ against the hypothesis $\theta = \theta''$. Moreover, for each number θ'' greater than θ' , the foregoing argument holds. That is, $C = \{(x_1, \dots, x_n) : \sum_{i=1}^n x_i^2 \geq c\}$ is a uniformly most powerful critical region of size α for testing $H_0 : \theta = \theta'$ against $H_1 : \theta > \theta'$. If x_1, x_2, \dots, x_n denote the experimental values of X_1, X_2, \dots, X_n , then $H_0 : \theta = \theta'$ is rejected at the significance level α , and $H_1 : \theta > \theta'$ is accepted if $\sum_{i=1}^n x_i^2 \geq c$; otherwise, $H_0 : \theta = \theta'$ is accepted.

If, in the preceding discussion, we take $n = 15$, $\alpha = 0.05$, and $\theta' = 3$, then the two hypotheses are $H_0 : \theta = 3$ and $H_1 : \theta > 3$. Using R, $c/3$ is computed by `qchisq(0.95, 15) = 24.996`. Hence, $c = 74.988$. ■

Example 8.2.3. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta, 1)$, where θ is unknown. It will be shown that there is no uniformly most powerful test of the simple hypothesis $H_0 : \theta = \theta'$, where θ' is a fixed number against the alternative composite hypothesis $H_1 : \theta \neq \theta'$. Thus $\Omega = \{\theta : -\infty < \theta < \infty\}$. Let θ'' be a number not equal to θ' . Let k be a positive number and consider

$$\frac{(1/2\pi)^{n/2} \exp \left[-\sum_1^n (x_i - \theta')^2 / 2 \right]}{(1/2\pi)^{n/2} \exp \left[-\sum_1^n (x_i - \theta'')^2 / 2 \right]} \leq k.$$

The preceding inequality may be written as

$$\exp \left\{ -(\theta'' - \theta') \sum_1^n x_i + \frac{n}{2} [(\theta'')^2 - (\theta')^2] \right\} \leq k$$

or

$$(\theta'' - \theta') \sum_1^n x_i \geq \frac{n}{2} [(\theta'')^2 - (\theta')^2] - \log k.$$

This last inequality is equivalent to

$$\sum_1^n x_i \geq \frac{n}{2} (\theta'' + \theta') - \frac{\log k}{\theta'' - \theta'},$$

provided that $\theta'' > \theta'$, and it is equivalent to

$$\sum_1^n x_i \leq \frac{n}{2} (\theta'' + \theta') - \frac{\log k}{\theta'' - \theta'}$$

if $\theta'' < \theta'$. The first of these two expressions defines a best critical region for testing $H_0 : \theta = \theta'$ against the hypothesis $\theta = \theta''$ provided that $\theta'' > \theta'$, while the second expression defines a best critical region for testing $H_0 : \theta = \theta'$ against the hypothesis $\theta = \theta''$ provided that $\theta'' < \theta'$. That is, a best critical region for testing the simple hypothesis against an alternative simple hypothesis, say $\theta = \theta' + 1$, does not serve as a best critical region for testing $H_0 : \theta = \theta'$ against the alternative simple hypothesis $\theta = \theta' - 1$. By definition, then, there is no uniformly most powerful test in the case under consideration.

It should be noted that had the alternative composite hypothesis been one-sided, either $H_1 : \theta > \theta'$ or $H_1 : \theta < \theta'$, a uniformly most powerful test would exist in each instance. ■

Example 8.2.4. In Exercise 8.1.10, the reader was asked to show that if a random sample of size $n = 10$ is taken from a Poisson distribution with mean θ , the critical region defined by $\sum_1^n x_i \geq 3$ is a best critical region for testing $H_0 : \theta = 0.1$ against

$H_1 : \theta = 0.5$. This critical region is also a uniformly most powerful one for testing $H_0 : \theta = 0.1$ against $H_1 : \theta > 0.1$ because, with $\theta'' > 0.1$,

$$\frac{(0.1)^{\sum x_i} e^{-10(0.1)} / (x_1! x_2! \cdots x_n!)}{(\theta'')^{\sum x_i} e^{-10(\theta'')} / (x_1! x_2! \cdots x_n!)} \leq k$$

is equivalent to

$$\left(\frac{0.1}{\theta''}\right)^{\sum x_i} e^{-10(0.1 - \theta'')} \leq k.$$

The preceding inequality may be written as

$$\left(\sum_1^n x_i\right) (\log 0.1 - \log \theta'') \leq \log k + 10(1 - \theta'')$$

or, since $\theta'' > 0.1$, equivalently as

$$\sum_1^n x_i \geq \frac{\log k + 10 - 10\theta''}{\log 0.1 - \log \theta''}.$$

Of course, $\sum_1^n x_i \geq 3$ is of the latter form. ■

Let us make an important observation, although obvious when pointed out. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that has pdf $f(x; \theta)$, $\theta \in \Omega$. Suppose that $Y = u(X_1, X_2, \dots, X_n)$ is a sufficient statistic for θ . In accordance with the factorization theorem, the joint pdf of X_1, X_2, \dots, X_n may be written

$$L(\theta; x_1, x_2, \dots, x_n) = k_1[u(x_1, x_2, \dots, x_n); \theta] k_2(x_1, x_2, \dots, x_n),$$

where $k_2(x_1, x_2, \dots, x_n)$ does not depend upon θ . Consequently, the ratio

$$\frac{L(\theta'; x_1, x_2, \dots, x_n)}{L(\theta''; x_1, x_2, \dots, x_n)} = \frac{k_1[u(x_1, x_2, \dots, x_n); \theta']}{k_1[u(x_1, x_2, \dots, x_n); \theta'']}$$

depends upon x_1, x_2, \dots, x_n only through $u(x_1, x_2, \dots, x_n)$. Accordingly, if there is a sufficient statistic $Y = u(X_1, X_2, \dots, X_n)$ for θ and if a best test or a uniformly most powerful test is desired, there is no need to consider tests that are based upon any statistic other than the sufficient statistic. This result supports the importance of sufficiency.

In the above examples, we have presented uniformly most powerful tests. For some families of pdfs and hypotheses, we can obtain general forms of such tests. We sketch these results for the general one-sided hypotheses of the form

$$H_0 : \theta \leq \theta' \text{ versus } H_1 : \theta > \theta'. \quad (8.2.1)$$

The other one-sided hypotheses with the null hypothesis $H_0 : \theta \geq \theta'$, is completely analogous. Note that the null hypothesis of (8.2.1) is a composite hypothesis. Recall from Chapter 4 that the level of a test for the hypotheses (8.2.1) is defined by

$\max_{\theta \leq \theta'} \gamma(\theta)$, where $\gamma(\theta)$ is the power function of the test. That is, the significance level is the maximum probability of Type I error.

Let $\mathbf{X}' = (X_1, \dots, X_n)$ be a random sample with common pdf (or pmf) $f(x; \theta)$, $\theta \in \Omega$, and, hence with the likelihood function

$$L(\theta, \mathbf{x}) = \prod_{i=1}^n f(x_i; \theta), \quad \mathbf{x}' = (x_1, \dots, x_n).$$

We consider the family of pdfs that has monotone likelihood ratio as defined next.

Definition 8.2.2. We say that the likelihood $L(\theta, \mathbf{x})$ has **monotone likelihood ratio (mlr)** in the statistic $y = u(\mathbf{x})$ if, for $\theta_1 < \theta_2$, the ratio

$$\frac{L(\theta_1, \mathbf{x})}{L(\theta_2, \mathbf{x})} \quad (8.2.2)$$

is a monotone function of $y = u(\mathbf{x})$.

Assume then that our likelihood function $L(\theta, \mathbf{x})$ has a monotone decreasing likelihood ratio in the statistic $y = u(\mathbf{x})$. Then the ratio in (8.2.2) is equal to $g(y)$, where g is a decreasing function. The case where the likelihood function has a monotone increasing likelihood ratio (i.e., g is an increasing function) follows similarly by changing the sense of the inequalities below. Let α denote the significance level. Then we claim that the following test is UMP level α for the hypotheses (8.2.1):

$$\text{Reject } H_0 \text{ if } Y \geq c_Y, \quad (8.2.3)$$

where c_Y is determined by $\alpha = P_{\theta'}[Y \geq c_Y]$. To show this claim, first consider the simple null hypothesis $H'_0 : \theta = \theta'$. Let $\theta'' > \theta'$ be arbitrary but fixed. Let C denote the most powerful critical region for θ' versus θ'' . By the Neyman–Pearson Theorem, C is defined by

$$\frac{L(\theta', \mathbf{X})}{L(\theta'', \mathbf{X})} \leq k \text{ if and only if } \mathbf{X} \in C,$$

where k is determined by $\alpha = P_{\theta'}[\mathbf{X} \in C]$. But by Definition 8.2.2, because $\theta'' > \theta'$,

$$\frac{L(\theta', \mathbf{X})}{L(\theta'', \mathbf{X})} = g(Y) \leq k \Leftrightarrow Y \geq g^{-1}(k),$$

where $g^{-1}(k)$ satisfies $\alpha = P_{\theta'}[Y \geq g^{-1}(k)]$; i.e., $c_Y = g^{-1}(k)$. Hence the Neyman–Pearson test is equivalent to the test defined by (8.2.3). Furthermore, the test is UMP for θ' versus $\theta'' > \theta'$ because the test only depends on $\theta'' > \theta'$ and $g^{-1}(k)$ is uniquely determined under θ' .

Let $\gamma_Y(\theta)$ denote the power function of the test (8.2.3). To finish, we need to show that $\max_{\theta \leq \theta'} \gamma_Y(\theta) = \alpha$. But this follows immediately if we can show that $\gamma_Y(\theta)$ is a nondecreasing function. To see this, let $\theta_1 < \theta_2$. Note that since $\theta_1 < \theta_2$, the test (8.2.3) is the most powerful test for testing θ_1 versus θ_2 with the level $\gamma_Y(\theta_1)$. By Corollary 8.1.1, the power of the test at θ_2 must not be below the level; i.e., $\gamma_Y(\theta_2) \geq \gamma_Y(\theta_1)$. Hence $\gamma_Y(\theta)$ is a nondecreasing function. Since the power function is nondecreasing, it follows from Definition 8.1.2 that the mlr tests are unbiased tests for the hypotheses (8.2.1); see Exercise 8.2.14.

Example 8.2.5. Let X_1, X_2, \dots, X_n be a random sample from a Bernoulli distribution with parameter $p = \theta$, where $0 < \theta < 1$. Let $\theta' < \theta''$. Consider the ratio of likelihoods

$$\frac{L(\theta'; x_1, x_2, \dots, x_n)}{L(\theta''; x_1, x_2, \dots, x_n)} = \frac{(\theta')^{\sum x_i} (1 - \theta')^{n - \sum x_i}}{(\theta'')^{\sum x_i} (1 - \theta'')^{n - \sum x_i}} = \left[\frac{\theta'(1 - \theta'')}{\theta''(1 - \theta')} \right]^{\sum x_i} \left(\frac{1 - \theta'}{1 - \theta''} \right)^n.$$

Since $\theta'/\theta'' < 1$ and $(1 - \theta'')/(1 - \theta') < 1$, so that $\theta'(1 - \theta'')/\theta''(1 - \theta') < 1$, the ratio is a decreasing function of $y = \sum x_i$. Thus we have a monotone likelihood ratio in the statistic $Y = \sum X_i$.

Consider the hypotheses

$$H_0 : \theta \leq \theta' \text{ versus } H_1 : \theta > \theta'. \quad (8.2.4)$$

By our discussion above, the UMP level α decision rule for testing H_0 versus H_1 is given by

$$\text{Reject } H_0 \text{ if } Y = \sum_{i=1}^n X_i \geq c,$$

where c is such that $\alpha = P_{\theta'}[Y \geq c]$. ■

In the last example concerning a Bernoulli pmf, we obtained a UMP test by showing that its likelihood possesses mlr. The Bernoulli distribution is a regular case of the exponential family and our argument, under the one assumption below, can be generalized to the entire regular exponential family. To show this, suppose that the random sample X_1, X_2, \dots, X_n arises from a pdf or pmf representing a regular case of the exponential class, namely,

$$f(x; \theta) = \begin{cases} \exp[p(\theta)K(x) + H(x) + q(\theta)] & x \in \mathcal{S} \\ 0 & \text{elsewhere,} \end{cases}$$

where the support of X , \mathcal{S} , is free of θ . Further assume that $p(\theta)$ is an increasing function of θ . Then

$$\begin{aligned} \frac{L(\theta')}{L(\theta'')} &= \frac{\exp \left[p(\theta') \sum_1^n K(x_i) + \sum_1^n H(x_i) + nq(\theta') \right]}{\exp \left[p(\theta'') \sum_1^n K(x_i) + \sum_1^n H(x_i) + nq(\theta'') \right]} \\ &= \exp \left\{ [p(\theta') - p(\theta'')] \sum_1^n K(x_i) + n[q(\theta') - q(\theta'')] \right\}. \end{aligned}$$

If $\theta' < \theta''$, $p(\theta)$ being an increasing function, requires this ratio to be a decreasing function of $y = \sum_1^n K(x_i)$. Thus, we have a monotone likelihood ratio in the statistic $Y = \sum_1^n K(X_i)$. Hence consider the hypotheses

$$H_0 : \theta \leq \theta' \text{ versus } H_1 : \theta > \theta'. \quad (8.2.5)$$

By our discussion above concerning mlr, the UMP level α decision rule for testing H_0 versus H_1 is given by

$$\text{Reject } H_0 \text{ if } Y = \sum_{i=1}^n K(X_i) \geq c,$$

where c is such that $\alpha = P_{\theta'}[Y \geq c]$. Furthermore, the power function of this test is an increasing function in θ .

For the record, consider the other one-sided alternative hypotheses,

$$H_0 : \theta \geq \theta' \text{ versus } H_1 : \theta < \theta'. \quad (8.2.6)$$

The UMP level α decision rule is, for $p(\theta)$ an increasing function,

$$\text{Reject } H_0 \text{ if } Y = \sum_{i=1}^n K(X_i) \leq c,$$

where c is such that $\alpha = P_{\theta'}[Y \leq c]$.

If in the preceding situation with monotone likelihood ratio we test $H_0 : \theta = \theta'$ against $H_1 : \theta > \theta'$, then $\sum K(x_i) \geq c$ would be a uniformly most powerful critical region. From the likelihood ratios displayed in Examples 8.2.2–8.2.5, we see immediately that the respective critical regions

$$\sum_{i=1}^n x_i^2 \geq c, \quad \sum_{i=1}^n x_i \geq c, \quad \sum_{i=1}^n x_i \geq c, \quad \sum_{i=1}^n x_i \geq c$$

are uniformly most powerful for testing $H_0 : \theta = \theta'$ against $H_1 : \theta > \theta'$.

There is a final remark that should be made about uniformly most powerful tests. Of course, in Definition 8.2.1, the word *uniformly* is associated with θ ; that is, C is a best critical region of size α for testing $H_0 : \theta = \theta_0$ against all θ values given by the composite alternative H_1 . However, suppose that the form of such a region is

$$u(x_1, x_2, \dots, x_n) \leq c.$$

Then this form provides uniformly most powerful critical regions for all attainable α values by, of course, appropriately changing the value of c . That is, there is a certain uniformity property, also associated with α , that is not always noted in statistics texts.

EXERCISES

- 8.2.1.** Let X have the pmf $f(x; \theta) = \theta^x(1 - \theta)^{1-x}$, $x = 0, 1$, zero elsewhere. We test the simple hypothesis $H_0 : \theta = \frac{1}{4}$ against the alternative composite hypothesis $H_1 : \theta < \frac{1}{4}$ by taking a random sample of size 10 and rejecting $H_0 : \theta = \frac{1}{4}$ if and only if the observed values x_1, x_2, \dots, x_{10} of the sample observations are such that $\sum_1^{10} x_i \leq 1$. Find the power function $\gamma(\theta)$, $0 < \theta \leq \frac{1}{4}$, of this test.

8.2.2. Let X have a pdf of the form $f(x; \theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere. Let $Y_1 < Y_2 < Y_3 < Y_4$ denote the order statistics of a random sample of size 4 from this distribution. Let the observed value of Y_4 be y_4 . We reject $H_0 : \theta = 1$ and accept $H_1 : \theta \neq 1$ if either $y_4 \leq \frac{1}{2}$ or $y_4 > 1$. Find the power function $\gamma(\theta)$, $0 < \theta$, of the test.

8.2.3. Consider a normal distribution of the form $N(\theta, 4)$. The simple hypothesis $H_0 : \theta = 0$ is rejected, and the alternative composite hypothesis $H_1 : \theta > 0$ is accepted if and only if the observed mean \bar{x} of a random sample of size 25 is greater than or equal to $\frac{3}{5}$. Find the power function $\gamma(\theta)$, $0 \leq \theta$, of this test.

8.2.4. Consider the distributions $N(\mu_1, 400)$ and $N(\mu_2, 225)$. Let $\theta = \mu_1 - \mu_2$. Let \bar{x} and \bar{y} denote the observed means of two independent random samples, each of size n , from these two distributions. We reject $H_0 : \theta = 0$ and accept $H_1 : \theta > 0$ if and only if $\bar{x} - \bar{y} \geq c$. If $\gamma(\theta)$ is the power function of this test, find n and c so that $\gamma(0) = 0.05$ and $\gamma(10) = 0.90$, approximately.

8.2.5. Consider Example 8.2.2. Show that $L(\theta)$ has a monotone likelihood ratio in the statistic $\sum_{i=1}^n X_i^2$. Use this to determine the UMP test for $H_0 : \theta = \theta'$, where θ' is a fixed positive number, versus $H_1 : \theta < \theta'$.

8.2.6. If, in Example 8.2.2 of this section, $H_0 : \theta = \theta'$, where θ' is a fixed positive number, and $H_1 : \theta \neq \theta'$, show that there is no uniformly most powerful test for testing H_0 against H_1 .

8.2.7. Let X_1, X_2, \dots, X_{25} denote a random sample of size 25 from a normal distribution $N(\theta, 100)$. Find a uniformly most powerful critical region of size $\alpha = 0.10$ for testing $H_0 : \theta = 75$ against $H_1 : \theta > 75$.

8.2.8. Let X_1, X_2, \dots, X_n denote a random sample from a normal distribution $N(\theta, 16)$. Find the sample size n and a uniformly most powerful test of $H_0 : \theta = 25$ against $H_1 : \theta < 25$ with power function $\gamma(\theta)$ so that approximately $\gamma(25) = 0.10$ and $\gamma(23) = 0.90$.

8.2.9. Consider a distribution having a pmf of the form $f(x; \theta) = \theta^x(1-\theta)^{1-x}$, $x = 0, 1$, zero elsewhere. Let $H_0 : \theta = \frac{1}{20}$ and $H_1 : \theta > \frac{1}{20}$. Use the Central Limit Theorem to determine the sample size n of a random sample so that a uniformly most powerful test of H_0 against H_1 has a power function $\gamma(\theta)$, with approximately $\gamma(\frac{1}{20}) = 0.05$ and $\gamma(\frac{1}{10}) = 0.90$.

8.2.10. Illustrative Example 8.2.1 of this section dealt with a random sample of size $n = 2$ from a gamma distribution with $\alpha = 1$, $\beta = \theta$. Thus the mgf of the distribution is $(1 - \theta t)^{-1}$, $t < 1/\theta$, $\theta \geq 2$. Let $Z = X_1 + X_2$. Show that Z has a gamma distribution with $\alpha = 2$, $\beta = \theta$. Express the power function $\gamma(\theta)$ of Example 8.2.1 in terms of a single integral. Generalize this for a random sample of size n .

8.2.11. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pdf $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, zero elsewhere, where $\theta > 0$. Show the likelihood has mlr in the statistic $\prod_{i=1}^n X_i$. Use this to determine the UMP test for $H_0 : \theta = \theta'$ against $H_1 : \theta < \theta'$, for fixed $\theta' > 0$.

8.2.12. Let X have the pdf $f(x; \theta) = \theta^x(1 - \theta)^{1-x}$, $x = 0, 1$, zero elsewhere. We test $H_0 : \theta = \frac{1}{2}$ against $H_1 : \theta < \frac{1}{2}$ by taking a random sample X_1, X_2, \dots, X_5 of size $n = 5$ and rejecting H_0 if $Y = \sum_1^n X_i$ is observed to be less than or equal to a constant c .

- (a) Show that this is a uniformly most powerful test.
- (b) Find the significance level when $c = 1$.
- (c) Find the significance level when $c = 0$.
- (d) By using a *randomized test*, as discussed in Example 4.6.4, modify the tests given in parts (b) and (c) to find a test with significance level $\alpha = \frac{2}{32}$.

8.2.13. Let X_1, \dots, X_n denote a random sample from a gamma-type distribution with $\alpha = 2$ and $\beta = \theta$. Let $H_0 : \theta = 1$ and $H_1 : \theta > 1$.

- (a) Show that there exists a uniformly most powerful test for H_0 against H_1 , determine the statistic Y upon which the test may be based, and indicate the nature of the best critical region.
- (b) Find the pdf of the statistic Y in part (a). If we want a significance level of 0.05, write an equation that can be used to determine the critical region. Let $\gamma(\theta)$, $\theta \geq 1$, be the power function of the test. Express the power function as an integral.

8.2.14. Show that the mlr test defined by expression (8.2.3) is an unbiased test for the hypotheses (8.2.1).

8.3 Likelihood Ratio Tests

In the first section of this chapter, we presented the most powerful tests for simple versus simple hypotheses. In the second section, we extended this theory to uniformly most powerful tests for essentially one-sided alternative hypotheses and families of distributions that have a monotone likelihood ratio. What about the general case? That is, suppose the random variable X has pdf or pmf $f(x; \boldsymbol{\theta})$, where $\boldsymbol{\theta}$ is a vector of parameters in Ω . Let $\omega \subset \Omega$ and consider the hypotheses

$$H_0 : \boldsymbol{\theta} \in \omega \text{ versus } H_1 : \boldsymbol{\theta} \in \Omega \cap \omega^c. \quad (8.3.1)$$

There are complications in extending the optimal theory to this general situation, which are addressed in more advanced books; see, in particular, Lehmann (1986). We illustrate some of these complications with an example. Suppose X has a $N(\theta_1, \theta_2)$ distribution and that we want to test $\theta_1 = \theta'_1$, where θ'_1 is specified. In the notation of (8.3.1), $\boldsymbol{\theta} = (\theta_1, \theta_2)$, $\Omega = \{\boldsymbol{\theta} : -\infty < \theta_1 < \infty, \theta_2 > 0\}$, and $\omega = \{\boldsymbol{\theta} : \theta_1 = \theta'_1, \theta_2 > 0\}$. Notice that $H_0 : \boldsymbol{\theta} \in \omega$ is a composite null hypothesis. Let X_1, \dots, X_n be a random sample on X .

Assume for the moment that θ_2 is known. Then H_0 becomes the simple hypothesis $\theta_1 = \theta'_1$. This is essentially the situation discussed in Example 8.2.3. There

it was shown that no UMP test exists for this situation. If we restrict attention to the class of unbiased tests (Definition 8.1.2), then a theory of best tests can be constructed; see Lehmann (1986). For our illustrative example, as Exercise 8.3.21 shows, the test based on the critical region

$$C_2 = \left\{ |\bar{X} - \theta'_1| > \sqrt{\frac{\theta_2}{n}} z_{\alpha/2} \right\}$$

is unbiased. Then it follows from Lehmann that it is an UMP unbiased level α test.

In practice, though, the variance θ_2 is unknown. In this case, theory for optimal tests can be constructed using the concept of what are called conditional tests. We do not pursue this any further in this text, but refer the interested reader to Lehmann (1986).

Recall from Chapter 6 that the likelihood ratio tests (6.3.3) can be used to test general hypotheses such as (8.3.1). While in general the exact null distribution of the test statistic cannot be determined, under regularity conditions the likelihood ratio test statistic is asymptotically χ^2 under H_0 . Hence we can obtain an approximate test in most situations. Although, there is no guarantee that likelihood ratio tests are optimal, similar to tests based on the Neyman–Pearson Theorem, they are based on a ratio of likelihood functions and, in many situations, are asymptotically optimal.

In the example above on testing for the mean of a normal distribution, with known variance, the likelihood ratio test is the same as the UMP unbiased test. When the variance is unknown, the likelihood ratio test results in the one-sample t -test as shown in Example 6.5.1 of Chapter 6. This is the same as the conditional test discussed in Lehmann (1986).

In the remainder of this section, we present likelihood ratio tests for situations when sampling from normal distributions.

8.3.1 Likelihood Ratio Tests for Testing Means of Normal Distributions

In Example 6.5.1 of Chapter 6, we derived the likelihood ratio test for the one-sample t -test to test for the mean of a normal distribution with unknown variance. In the next example, we derive the likelihood ratio test for comparing the means of two independent normal distributions. We then discuss the power functions for both of these tests.

Example 8.3.1. Let the independent random variables X and Y have distributions that are $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_3)$, where the means θ_1 and θ_2 and common variance θ_3 are unknown. Then $\Omega = \{(\theta_1, \theta_2, \theta_3) : -\infty < \theta_1 < \infty, -\infty < \theta_2 < \infty, 0 < \theta_3 < \infty\}$. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m denote independent random samples from these distributions. The hypothesis $H_0 : \theta_1 = \theta_2$, unspecified, and θ_3 unspecified, is to be tested against all alternatives. Then $\omega = \{(\theta_1, \theta_2, \theta_3) : -\infty < \theta_1 = \theta_2 < \infty, 0 < \theta_3 < \infty\}$. Here $X_1, X_2, \dots, X_n, Y_1, Y_2, \dots, Y_m$ are $n + m > 2$ mutually

independent random variables having the likelihood functions

$$L(\omega) = \left(\frac{1}{2\pi\theta_3} \right)^{(n+m)/2} \exp \left\{ -\frac{1}{2\theta_3} \left[\sum_1^n (x_i - \theta_1)^2 + \sum_1^m (y_i - \theta_1)^2 \right] \right\}$$

and

$$L(\Omega) = \left(\frac{1}{2\pi\theta_3} \right)^{(n+m)/2} \exp \left\{ -\frac{1}{2\theta_3} \left[\sum_1^n (x_i - \theta_1)^2 + \sum_1^m (y_i - \theta_2)^2 \right] \right\}.$$

If $\partial \log L(\omega)/\partial\theta_1$ and $\partial \log L(\omega)/\partial\theta_3$ are equated to zero, then (Exercise 8.3.2)

$$\begin{aligned} \sum_1^n (x_i - \theta_1) + \sum_1^m (y_i - \theta_1) &= 0 \\ \frac{1}{\theta_3} \left[\sum_1^n (x_i - \theta_1)^2 + \sum_1^m (y_i - \theta_1)^2 \right] &= n + m. \end{aligned} \quad (8.3.2)$$

The solutions for θ_1 and θ_3 are, respectively,

$$\begin{aligned} u &= (n + m)^{-1} \left\{ \sum_1^n x_i + \sum_1^m y_i \right\} \\ w &= (n + m)^{-1} \left\{ \sum_1^n (x_i - u)^2 + \sum_1^m (y_i - u)^2 \right\}. \end{aligned}$$

Further, u and w maximize $L(\omega)$. The maximum is

$$L(\hat{\omega}) = \left(\frac{e^{-1}}{2\pi w} \right)^{(n+m)/2}.$$

In a like manner, if

$$\frac{\partial \log L(\Omega)}{\partial\theta_1}, \quad \frac{\partial \log L(\Omega)}{\partial\theta_2}, \quad \frac{\partial \log L(\Omega)}{\partial\theta_3}$$

are equated to zero, then (Exercise 8.3.3)

$$\begin{aligned} \sum_1^n (x_i - \theta_1) &= 0 \\ \sum_1^m (y_i - \theta_2) &= 0 \\ -(n + m) + \frac{1}{\theta_3} \left[\sum_1^n (x_i - \theta_1)^2 + \sum_1^m (y_i - \theta_2)^2 \right] &= 0. \end{aligned} \quad (8.3.3)$$

The solutions for θ_1 , θ_2 , and θ_3 are, respectively,

$$\begin{aligned} u_1 &= n^{-1} \sum_1^n x_i \\ u_2 &= m^{-1} \sum_1^m y_i \\ w' &= (n+m)^{-1} \left[\sum_1^n (x_i - u_1)^2 + \sum_1^m (y_i - u_2)^2 \right], \end{aligned}$$

and, further, u_1 , u_2 , and w' maximize $L(\Omega)$. The maximum is

$$L(\hat{\Omega}) = \left(\frac{e^{-1}}{2\pi w'} \right)^{(n+m)/2},$$

so that

$$\Lambda(x_1, \dots, x_n, y_1, \dots, y_m) = \Lambda = \frac{L(\hat{\omega})}{L(\hat{\Omega})} = \left(\frac{w'}{w} \right)^{(n+m)/2}.$$

The random variable defined by $\Lambda^{2/(n+m)}$ is

$$\frac{\sum_1^n (X_i - \bar{X})^2 + \sum_1^m (Y_i - \bar{Y})^2}{\sum_1^n \{X_i - [(n\bar{X} + m\bar{Y})/(n+m)]\}^2 + \sum_1^m \{Y_i - [(n\bar{X} + m\bar{Y})/(n+m)]\}^2}.$$

Now

$$\begin{aligned} \sum_1^n \left(X_i - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2 &= \sum_1^n \left[(X_i - \bar{X}) + \left(\bar{X} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right) \right]^2 \\ &= \sum_1^n (X_i - \bar{X})^2 + n \left(\bar{X} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2 \end{aligned}$$

and

$$\begin{aligned} \sum_1^m \left(Y_i - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2 &= \sum_1^m \left[(Y_i - \bar{Y}) + \left(\bar{Y} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right) \right]^2 \\ &= \sum_1^m (Y_i - \bar{Y})^2 + m \left(\bar{Y} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2. \end{aligned}$$

But

$$n \left(\bar{X} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2 = \frac{m^2 n}{(n+m)^2} (\bar{X} - \bar{Y})^2$$

and

$$m \left(\bar{Y} - \frac{n\bar{X} + m\bar{Y}}{n+m} \right)^2 = \frac{n^2 m}{(n+m)^2} (\bar{X} - \bar{Y})^2.$$

Hence the random variable defined by $\Lambda^{2/(n+m)}$ may be written

$$\begin{aligned} & \frac{\sum_1^n (X_i - \bar{X})^2 + \sum_1^m (Y_i - \bar{Y})^2}{\sum_1^n (X_i - \bar{X})^2 + \sum_1^m (Y_i - \bar{Y})^2 + [nm/(n+m)](\bar{X} - \bar{Y})^2} \\ &= \frac{1}{1 + \frac{[nm/(n+m)](\bar{X} - \bar{Y})^2}{\sum_1^n (X_i - \bar{X})^2 + \sum_1^m (Y_i - \bar{Y})^2}}. \end{aligned}$$

If the hypothesis $H_0 : \theta_1 = \theta_2$ is true, the random variable

$$T = \sqrt{\frac{nm}{n+m}} (\bar{X} - \bar{Y}) \left\{ (n+m-2)^{-1} \left[\sum_1^n (X_i - \bar{X})^2 + \sum_1^m (Y_i - \bar{Y})^2 \right] \right\}^{-1/2} \quad (8.3.4)$$

has, in accordance with Section 3.6, a t -distribution with $n+m-2$ degrees of freedom. Thus the random variable defined by $\Lambda^{2/(n+m)}$ is

$$\frac{n+m-2}{(n+m-2) + T^2}.$$

The test of H_0 against all alternatives may then be based on a t -distribution with $n+m-2$ degrees of freedom.

The likelihood ratio principle calls for the rejection of H_0 if and only if $\Lambda \leq \lambda_0 < 1$. Thus the significance level of the test is

$$\alpha = P_{H_0}[\Lambda(X_1, \dots, X_n, Y_1, \dots, Y_m) \leq \lambda_0].$$

However, $\Lambda(X_1, \dots, X_n, Y_1, \dots, Y_m) \leq \lambda_0$ is equivalent to $|T| \geq c$, and so

$$\alpha = P(|T| \geq c; H_0).$$

For given values of n and m , the number c is easily computed. In R, $c = qt(1 - \alpha/2, n+m-2)$. Then H_0 is rejected at a significance level α if and only if $|t| \geq c$, where t is the observed value of T . If, for instance, $n = 10$, $m = 6$, and $\alpha = 0.05$, then $c = qt(0.975, 14) = 2.1448$. ■

For this last example as well as the one-sample t -test derived in Example 6.5.1, it was found that the likelihood ratio test could be based on a statistic that, when the hypothesis H_0 is true, has a t -distribution. To help us compute the power functions of these tests at parameter points other than those described by the hypothesis H_0 , we turn to the following definition.

Definition 8.3.1. Let the random variable W be $N(\delta, 1)$; let the random variable V be $\chi^2(r)$, and let W and V be independent. The quotient

$$T = \frac{W}{\sqrt{V/r}}$$

is said to have a noncentral t -distribution with r degrees of freedom and noncentrality parameter δ . If $\delta = 0$, we say that T has a central t -distribution.

In the light of this definition, let us reexamine the t -statistics of Examples 6.5.1 and 8.3.1.

Example 8.3.2 (Power of the One Sample t -Test). For Example 6.5.1, consider a more general situation. Assume that X_1, \dots, X_n is a random sample on X that has a $N(\mu, \sigma^2)$ distribution. We are interested in testing $H_0 : \mu = \mu_0$ versus $H_1 : \mu \neq \mu_0$, where μ_0 is specified. Then from Example 6.5.1, the likelihood ratio test statistic is

$$\begin{aligned} t(X_1, \dots, X_n) &= \frac{\sqrt{n}(\bar{X} - \mu_0)}{\sqrt{\sum_1^n (X_i - \bar{X})^2 / (n-1)}} \\ &= \frac{\sqrt{n}(\bar{X} - \mu_0) / \sigma}{\sqrt{\sum_1^n (X_i - \bar{X})^2 / [\sigma^2(n-1)]}}. \end{aligned}$$

The hypothesis H_0 is rejected at level α if $|t| \geq t_{\alpha/2, n-1}$. Suppose $\mu_1 \neq \mu_0$ is an alternative of interest. Because $E_{\mu_1}[\sqrt{n}\bar{X}/\sigma\sqrt{n}\bar{X}/\sigma] = \sqrt{n}(\mu_1 - \mu_0)/\sigma$, the power of the test to detect μ_1 is

$$\gamma(\mu_1) = P(|t| \geq t_{\alpha/2, n-1}) = 1 - P(t \leq t_{\alpha/2, n-1}) + P(t \leq -t_{\alpha/2, n-1}), \quad (8.3.5)$$

where t has a noncentral t -distribution with noncentrality parameter $\delta = \sqrt{n}(\mu_1 - \mu_0)/\sigma$ and $n-1$ degrees of freedom. This is computed in R by the call

`1 - pt(tc, n-1, ncp=delta) + pt(-tc, n-1, ncp=delta)`

where `tc` is $t_{\alpha/2, n-1}$ and `delta` is the noncentrality parameter δ .

The following R code computes a graph of the power curve of this test. Notice that the horizontal range of the plot is the interval $[\mu_0 - 4\sigma/\sqrt{n}, \mu_0 + 4\sigma/\sqrt{n}]$. As indicated the parameters need to be set.

```
## Input mu0, sig, n, alpha.
fse = 4*sig/sqrt(n); maxmu = mu0 + fse; tc = qt(1-(alpha/2), n-1)
minmu = mu0 - fse; mu1 = seq(minmu, maxmu, .1)
delta = (mu1-mu0)/(sig/sqrt(n))
gs = 1 - pt(tc, n-1, ncp=delta) + pt(-tc, n-1, ncp=delta)
plot(gs~mu1, pch=" ", xlab=expression(mu[1]), ylab=expression(gamma))
lines(gs~mu1)
```

This code is the body of the function `tpowerg.R`. Exercise 8.3.5 discusses its use. ■

Example 8.3.3 (Power of the Two Sample t -Test). In Example 8.3.1 we had

$$T = \frac{W_2}{\sqrt{V_2/(n+m-2)}},$$

where

$$W_2 = \sqrt{\frac{nm}{n+m}}(\bar{X} - \bar{Y}) / \sigma$$

and

$$V_2 = \frac{\sum_{i=1}^n (X_i - \bar{X})^2 + \sum_{i=1}^m (Y_i - \bar{Y})^2}{\sigma^2}.$$

Here W_2 is $N[\sqrt{nm/(n+m)}(\theta_1 - \theta_2)/\sigma, 1]$, V_2 is $\chi^2(n+m-2)$, and W_2 and V_2 are independent. Accordingly, if $\theta_1 \neq \theta_2$, T has a noncentral t -distribution with $n+m-2$ degrees of freedom and noncentrality parameter $\delta_2 = \sqrt{nm/(n+m)}(\theta_1 - \theta_2)/\sigma$. It is interesting to note that $\delta_1 = \sqrt{n}\theta_1/\sigma$ measures the deviation of θ_1 from $\theta_1 = 0$ in units of the standard deviation σ/\sqrt{n} of \bar{X} . The noncentrality parameter $\delta_2 = \sqrt{nm/(n+m)}(\theta_1 - \theta_2)/\sigma$ is equal to the deviation of $\theta_1 - \theta_2$ from $\theta_1 - \theta_2 = 0$ in units of the standard deviation $\sigma/\sqrt{(n+m)/mn}$ of $\bar{X} - \bar{Y}$.

As in the last example, it is easy to write R code that evaluates power for this test. For a numerical illustration, assume that the common variance is $\theta_3 = 100$, $n = 20$, and $m = 15$. Suppose $\alpha = 0.05$ and we want to determine the power of the test to detect $\Delta = 5$, where $\Delta = \theta_1 - \theta_2$. In this case the critical value is $t_{0.25,33} = qt(.975, 33) = 2.0345$ and the noncentrality parameter is $\delta_2 = 1.4639$. The power is computed as

1- pt(2.0345, 33, ncp=1.4639) + pt(-2.0345, 33, ncp=1.4639) = 0.2954

Hence, the test has a 29.4% chance of detecting a difference in means of 5. ■

Remark 8.3.1. The one- and two-sample tests for normal means, presented in Examples 6.5.1 and 8.3.1, are the tests for normal means presented in most elementary statistics books. They are based on the assumption of normality. What if the underlying distributions are not normal? In that case, with finite variances, the t -test statistics for these situations are asymptotically correct. For example, consider the one-sample t -test. Suppose X_1, \dots, X_n are iid with a common nonnormal pdf that has mean θ_1 and finite variance σ^2 . The hypotheses remain the same, i.e., $H_0 : \theta_1 = \theta'_1$ versus $H_1 : \theta_1 \neq \theta'_1$. The t -test statistic, T_n , is given by

$$T_n = \frac{\sqrt{n}(\bar{X} - \theta'_1)}{S_n}, \quad (8.3.6)$$

where S_n is the sample standard deviation. Our critical region is $C_1 = \{|T_n| \geq t_{\alpha/2,n-1}\}$. Recall that $S_n \rightarrow \sigma$ in probability. Hence, by the Central Limit Theorem, under H_0 ,

$$T_n = \frac{\sigma}{S_n} \frac{\sqrt{n}(\bar{X} - \theta'_1)}{\sigma} \xrightarrow{D} Z, \quad (8.3.7)$$

where Z has a standard normal distribution. Hence the asymptotic test would use the critical region $C_2 = \{|T_n| \geq z_{\alpha/2}\}$. By (8.3.7) the critical region C_2 would have approximate size α . In practice, we would use C_1 , because t critical values are generally larger than z critical values and, hence, the use of C_1 would be conservative; i.e., the size of C_1 would be slightly smaller than that of C_2 . As Exercise 8.3.4 shows, the two-sample t -test is also asymptotically correct, provided the underlying distributions have the *same* variance. ■

For nonnormal situations where the distribution is “close” to the normal distribution, the t -test is essentially valid; i.e., the true level of significance is close to the nominal α . In terms of robustness, we would say that for these situations the t -test possesses **robustness of validity**. But the t -test may not possess **robustness of power**. For nonnormal situations, there are more powerful tests than the t -test; see Chapter 10 for discussion.

For finite sample sizes and for distributions that are decidedly not normal, very skewed for instance, the validity of the t -test may also be questionable, as we illustrate in the following simulation study.

Example 8.3.4 (Skewed Contaminated Normal Family of Distributions). Consider the random variable X given by

$$X = (1 - I_\epsilon)Z + I_\epsilon Y, \quad (8.3.8)$$

where Z has a $N(0, 1)$ distribution, Y has a $N(\mu_c, \sigma_c^2)$ distribution, I_ϵ has a $bin(1, \epsilon)$ distribution, and Z , Y , and I_ϵ are mutually independent. Assume that $\epsilon < 0.5$ and $\sigma_c > 1$, so that Y is the contaminating random variable in the mixture. If $\mu_c = 0$, then X has the contaminated normal distribution discussed in Section 3.4.1, which is symmetrically distributed about 0. For $\mu_c \neq 0$, the distribution of X , (8.3.8), is skewed and we call it the **skewed contaminated normal distribution**, $SCN(\epsilon, \sigma_c, \mu_c)$. Note that $E(X) = \epsilon\mu_c$ and in Exercise 8.3.18 the cdf and pdf of X are derived. The R function `rscn` generates random variates from this distribution.

In this example, we show the results of a small simulation study on the validity of the t -test for random samples from the distribution of X . Consider the one-sided hypotheses

$$H_0 : \mu = \mu_X \text{ versus } H_1 : \mu < \mu_X.$$

Let X_1, X_2, \dots, X_n be a random sample from the distribution of X . As a test statistic we consider the t -test discussed in Example 4.5.4, which is also given in expression (8.3.6); that is, the test statistic is $T_n = (\bar{X} - \mu_X)/(S_n/\sqrt{n})$, where \bar{X} and S_n are the sample mean and standard deviation of X_1, X_2, \dots, X_n , respectively. We set the level of significance at $\alpha = 0.05$ and used the decision rule: Reject H_0 if $T_n \leq t_{0.05, n-1}$. For the study, we set $n = 30$, $\epsilon = 0.20$, and $\sigma_c = 25$. For μ_c , we selected the five values of 0, 5, 10, 15, and 20, as shown in Table 8.3.1. For each of these five situations, we ran 10,000 simulations and recorded $\hat{\alpha}$, which is the number of rejections of H_0 divided by the number of simulations, i.e., the empirical α level.

For the test to be valid, $\hat{\alpha}$ should be close to the nominal value of 0.05. As Table 8.3.1 shows, though, for all cases other than $\mu_c = 0$, the t -test is quite liberal; that is, its empirical significance level far exceeds the nominal 0.05 level (as Exercise

Table 8.3.1: Empirical α Levels for the Nominal 0.05 t -Test of Example 8.3.4.

	Empirical α				
μ_c	0	5	10	15	20
$\hat{\alpha}$	0.0458	0.0961	0.1238	0.1294	0.1301

8.3.19 shows, the sampling error in the table is about 0.004). Note that when $\mu_c = 0$ the distribution of X is symmetric about 0 and in this case the empirical level is close to the nominal value of 0.05. ■

8.3.2 Likelihood Ratio Tests for Testing Variances of Normal Distributions

In this section, we discuss likelihood ratio tests for variances of normal distributions. In the next example, we begin with the two sample problem.

Example 8.3.5. In Example 8.3.1, in testing the equality of the means of two normal distributions, it was assumed that the unknown variances of the distributions were equal. Let us now consider the problem of testing the equality of these two unknown variances. We are given the independent random samples X_1, \dots, X_n and Y_1, \dots, Y_m from the distributions, which are $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_4)$, respectively. We have

$$\Omega = \{(\theta_1, \theta_2, \theta_3, \theta_4) : -\infty < \theta_1, \theta_2 < \infty, 0 < \theta_3, \theta_4 < \infty\}.$$

The hypothesis $H_0 : \theta_3 = \theta_4$, unspecified, with θ_1 and θ_2 also unspecified, is to be tested against all alternatives. Then

$$\omega = \{(\theta_1, \theta_2, \theta_3, \theta_4) : -\infty < \theta_1, \theta_2 < \infty, 0 < \theta_3 = \theta_4 < \infty\}.$$

It is easy to show (see Exercise 8.3.11) that the statistic defined by $\Lambda = L(\hat{\omega})/L(\hat{\Omega})$ is a function of the statistic

$$F = \frac{\sum_{i=1}^n (X_i - \bar{X})^2 / (n-1)}{\sum_{i=1}^m (Y_i - \bar{Y})^2 / (m-1)}. \quad (8.3.9)$$

If $\theta_3 = \theta_4$, this statistic F has an F -distribution with $n-1$ and $m-1$ degrees of freedom. The hypothesis that $(\theta_1, \theta_2, \theta_3, \theta_4) \in \omega$ is rejected if the computed $F \leq c_1$ or if the computed $F \geq c_2$. The constants c_1 and c_2 are usually selected so that, if $\theta_3 = \theta_4$,

$$P(F \leq c_1) = P(F \geq c_2) = \frac{\alpha_1}{2},$$

where α_1 is the desired significance level of this test. The power function of this test is derived in Exercise 8.3.10. ■

Remark 8.3.2. We caution the reader on this last test for the equality of two variances. In Remark 8.3.1, we discussed that the one- and two-sample t -tests for means are asymptotically correct. The two-sample variance test of the last example is not, however; see, for example, page 143 of Hettmansperger and McKean (2011). If the underlying distributions are not normal, then the F -critical values may be far from valid critical values (unlike the t -critical values for the means tests as discussed in Remark 8.3.1). In a large simulation study, Conover, Johnson, and Johnson (1981) showed that instead of having the nominal size of $\alpha = 0.05$, the F -test for variances using the F -critical values could have significance levels as high as 0.80, in certain nonnormal situations. Thus the two-sample F -test for variances does not possess robustness of validity. It should only be used in situations where the assumption of normality can be justified. See Exercise 8.3.17 for an illustrative data set. ■

The corresponding likelihood ratio test for the variance of a normal distribution based on one sample is discussed in Exercise 8.3.9. The cautions raised in Remark 8.3.1, hold for this test also.

Example 8.3.6. Let the independent random variables X and Y have distributions that are $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_4)$. In Example 8.3.1, we derived the likelihood ratio test statistic T of the hypothesis $\theta_1 = \theta_2$ when $\theta_3 = \theta_4$, while in Example 8.3.5 we obtained the likelihood ratio test statistic F of the hypothesis $\theta_3 = \theta_4$. The hypothesis that $\theta_1 = \theta_2$ is rejected if the computed $|T| \geq c$, where the constant c is selected so that $\alpha_2 = P(|T| \geq c; \theta_1 = \theta_2, \theta_3 = \theta_4)$ is the assigned significance level of the test. We shall show that, if $\theta_3 = \theta_4$, the likelihood ratio test statistics for equality of variances and equality of means, respectively F and T , are independent. Among other things, this means that if these two tests based on F and T , respectively, are performed sequentially with significance levels α_1 and α_2 , the probability of accepting both these hypotheses, when they are true, is $(1 - \alpha_1)(1 - \alpha_2)$. Thus the significance level of this joint test is $\alpha = 1 - (1 - \alpha_1)(1 - \alpha_2)$.

Independence of F and T , when $\theta_3 = \theta_4$, can be established using sufficiency and completeness. The statistics \bar{X} , \bar{Y} , and $\sum_1^n (X_i - \bar{X})^2 + \sum_1^n (Y_i - \bar{Y})^2$ are joint complete sufficient statistics for the three parameters θ_1 , θ_2 , and $\theta_3 = \theta_4$. Obviously, the distribution of F does not depend upon θ_1 , θ_2 , or $\theta_3 = \theta_4$, and hence F is independent of the three joint complete sufficient statistics. However, T is a function of these three joint complete sufficient statistics alone, and, accordingly, T is independent of F . It is important to note that these two statistics are independent whether $\theta_1 = \theta_2$ or $\theta_1 \neq \theta_2$. This permits us to calculate probabilities other than the significance level of the test. For example, if $\theta_3 = \theta_4$ and $\theta_1 \neq \theta_2$, then

$$P(c_1 < F < c_2, |T| \geq c) = P(c_1 < F < c_2)P(|T| \geq c).$$

The second factor in the right-hand member is evaluated by using the probabilities of a noncentral t -distribution. Of course, if $\theta_3 = \theta_4$ and the difference $\theta_1 - \theta_2$ is large, we would want the preceding probability to be close to 1 because the event $\{c_1 < F < c_2, |T| \geq c\}$ leads to a correct decision, namely, accept $\theta_3 = \theta_4$ and reject $\theta_1 = \theta_2$. ■

EXERCISES

8.3.1. Verzani (2014) discusses a data set on healthy individuals, including their temperatures by gender. The data are in the file `tempbygender.rda` and the variables of interest are `maletemp` and `femaltemp`. Download this file from the site listed in the Preface.

- (a) Obtain comparison boxplots. Comment on the plots. Which, if any, gender seems to have lower temperatures? Based on the width of the boxplots, comment on the assumption of equal variances.
- (b) As discussed in Example 8.3.3, compute the two-sample, two-sided t -test that there is no difference in the true mean temperatures between genders. Obtain the p -value of the test and conclude in terms of the problem at the nominal α -level of 0.05.
- (c) Obtain a 95% confidence interval for the difference in means. What does it mean in terms of the problem?

8.3.2. Verify Equations (8.3.2) of Example 8.3.1 of this section.

8.3.3. Verify Equations (8.3.3) of Example 8.3.1 of this section.

8.3.4. Let X_1, \dots, X_n and Y_1, \dots, Y_m follow the location model

$$\begin{aligned} X_i &= \theta_1 + Z_i, \quad i = 1, \dots, n \\ Y_i &= \theta_2 + Z_{n+i}, \quad i = 1, \dots, m, \end{aligned}$$

where Z_1, \dots, Z_{n+m} are iid random variables with common pdf $f(z)$. Assume that $E(Z_i) = 0$ and $\text{Var}(Z_i) = \theta_3 < \infty$.

- (a) Show that $E(X_i) = \theta_1$, $E(Y_i) = \theta_2$, and $\text{Var}(X_i) = \text{Var}(Y_i) = \theta_3$.
- (b) Consider the hypotheses of Example 8.3.1, i.e.,

$$H_0 : \theta_1 = \theta_2 \text{ versus } H_1 : \theta_1 \neq \theta_2.$$

Show that under H_0 , the test statistic T given in expression (8.3.4) has a limiting $N(0, 1)$ distribution.

- (c) Using part (b), determine the corresponding large sample test (decision rule) of H_0 versus H_1 . (This shows that the test in Example 8.3.1 is asymptotically correct.)

8.3.5. In Example 8.3.2, the power function for the one-sample t -test is discussed.

- (a) Plot the power function for the following setup: X has a $N(\mu, \sigma^2)$ distribution; $H_0 : \mu = 50$ versus $H_1 : \mu \neq 50$; $\alpha = 0.05$; $n = 25$; and $\sigma = 10$.
- (b) Overlay the power curve in (a) with that for $\alpha = 0.01$. Comment.
- (c) Overlay the power curve in (a) with that for $n = 35$. Comment.

- (d) Determine the smallest value of n so the power exceeds 0.80 to detect $\mu = 53$.

Hint: Modify the R function `tpowerg.R` so it returns the power for a specified alternative.

8.3.6. The effect that a certain drug (Drug A) has on increasing blood pressure is a major concern. It is thought that a modification of the drug (Drug B) will lessen the increase in blood pressure. Let μ_A and μ_B be the true mean increases in blood pressure due to Drug A and B, respectively. The hypotheses of interest are $H_0 : \mu_A = \mu_B = 0$ versus $H_1 : \mu_A > \mu_B = 0$. The two-sample t -test statistic discussed in Example 8.3.3 is to be used to conduct the analysis. The nominal level is set at $\alpha = 0.05$. For the experimental design assume that the sample sizes are the same; i.e., $m = n$. Also, based on data from Drug A, $\sigma = 30$ seems to be a reasonable selection for the common standard deviation. Determine the common sample size, so that the difference in means $\mu_A - \mu_B = 12$ has an 80% detection rate. Suppose when the experiment is over, due to patients dropping out, the sample sizes for Drugs A and B are respectively $n = 72$ and $m = 68$. What was the actual power of the experiment to detect the difference of 12?

8.3.7. Show that the likelihood ratio principle leads to the same test when testing a simple hypothesis H_0 against an alternative simple hypothesis H_1 , as that given by the Neyman–Pearson theorem. Note that there are only two points in Ω .

8.3.8. Let X_1, X_2, \dots, X_n be a random sample from the normal distribution $N(\theta, 1)$. Show that the likelihood ratio principle for testing $H_0 : \theta = \theta'$, where θ' is specified, against $H_1 : \theta \neq \theta'$ leads to the inequality $|\bar{x} - \theta'| \geq c$.

- (a) Is this a uniformly most powerful test of H_0 against H_1 ?

- (b) Is this a uniformly most powerful unbiased test of H_0 against H_1 ?

8.3.9. Let X_1, X_2, \dots, X_n be iid $N(\theta_1, \theta_2)$. Show that the likelihood ratio principle for testing $H_0 : \theta_2 = \theta'_2$ specified, and θ_1 unspecified, against $H_1 : \theta_2 \neq \theta'_2$, θ_1 unspecified, leads to a test that rejects when $\sum_1^n (x_i - \bar{x})^2 \leq c_1$ or $\sum_1^n (x_i - \bar{x})^2 \geq c_2$, where $c_1 < c_2$ are selected appropriately.

8.3.10. For the situation discussed in Example 8.3.5, derive the power function for the likelihood ratio test statistic given in expression (8.3.9).

8.3.11. Let X_1, \dots, X_n and Y_1, \dots, Y_m be independent random samples from the distributions $N(\theta_1, \theta_3)$ and $N(\theta_2, \theta_4)$, respectively.

- (a) Show that the likelihood ratio for testing $H_0 : \theta_1 = \theta_2, \theta_3 = \theta_4$ against all alternatives is given by

$$\frac{\left[\sum_1^n (x_i - \bar{x})^2 / n \right]^{n/2} \left[\sum_1^m (y_i - \bar{y})^2 / m \right]^{m/2}}{\left\{ \left[\sum_1^n (x_i - u)^2 + \sum_1^m (y_i - u)^2 \right] / (m+n) \right\}^{(n+m)/2}},$$

where $u = (n\bar{x} + m\bar{y}) / (n+m)$.

- (b) Show that the likelihood ratio for testing $H_0 : \theta_3 = \theta_4$ with θ_1 and θ_2 unspecified can be based on the test statistic F given in expression (8.3.9).

8.3.12. Let $Y_1 < Y_2 < \dots < Y_5$ be the order statistics of a random sample of size $n = 5$ from a distribution with pdf $f(x; \theta) = \frac{1}{2}e^{-|x-\theta|}$, $-\infty < x < \infty$, for all real θ . Find the likelihood ratio test Λ for testing $H_0 : \theta = \theta_0$ against $H_1 : \theta \neq \theta_0$.

8.3.13. A random sample X_1, X_2, \dots, X_n arises from a distribution given by

$$H_0 : f(x; \theta) = \frac{1}{\theta}, \quad 0 < x < \theta, \quad \text{zero elsewhere,}$$

or

$$H_1 : f(x; \theta) = \frac{1}{\theta}e^{-x/\theta}, \quad 0 < x < \infty, \quad \text{zero elsewhere.}$$

Determine the likelihood ratio (Λ) test associated with the test of H_0 against H_1 .

8.3.14. Consider a random sample X_1, X_2, \dots, X_n from a distribution with pdf $f(x; \theta) = \theta(1-x)^{\theta-1}$, $0 < x < 1$, zero elsewhere, where $\theta > 0$.

- (a) Find the form of the uniformly most powerful test of $H_0 : \theta = 1$ against $H_1 : \theta > 1$.

- (b) What is the likelihood ratio Λ for testing $H_0 : \theta = 1$ against $H_1 : \theta \neq 1$?

8.3.15. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_n be independent random samples from two normal distributions $N(\mu_1, \sigma^2)$ and $N(\mu_2, \sigma^2)$, respectively, where σ^2 is the common but unknown variance.

- (a) Find the likelihood ratio Λ for testing $H_0 : \mu_1 = \mu_2 = 0$ against all alternatives.

- (b) Rewrite Λ so that it is a function of a statistic Z which has a well-known distribution.

- (c) Give the distribution of Z under both null and alternative hypotheses.

8.3.16. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample from a bivariate normal distribution with $\mu_1, \mu_2, \sigma_1^2 = \sigma_2^2 = \sigma^2, \rho = \frac{1}{2}$, where μ_1, μ_2 , and $\sigma^2 > 0$ are unknown real numbers. Find the likelihood ratio Λ for testing $H_0 : \mu_1 = \mu_2 = 0, \sigma^2$ unknown against all alternatives. The likelihood ratio Λ is a function of what statistic that has a well-known distribution?

8.3.17. Let X be a random variable with pdf $f_X(x) = (2b_X)^{-1} \exp\{-|x|/b_X\}$, for $-\infty < x < \infty$ and $b_X > 0$. First, show that the variance of X is $\sigma_X^2 = 2b_X^2$. Next, let Y , independent of X , have pdf $f_Y(y) = (2b_Y)^{-1} \exp\{-|y|/b_Y\}$, for $-\infty < y < \infty$ and $b_Y > 0$. Consider the hypotheses

$$H_0 : \sigma_X^2 = \sigma_Y^2 \text{ versus } H_1 : \sigma_X^2 > \sigma_Y^2.$$

To illustrate Remark 8.3.2 for testing these hypotheses, consider the following data set (data are also in the file `exercise8316.rda`). Sample 1 represents the values of a sample drawn on X with $b_X = 1$, while Sample 2 represents the values of a sample drawn on Y with $b_Y = 1$. Hence, in this case H_0 is true.

Sample 1	-0.389	-2.177	0.813	-0.001
	-0.110	-0.709	0.456	0.135
Sample 1	0.763	-0.570	-2.565	-1.733
	0.403	0.778	-0.115	
Sample 2	-1.067	-0.577	0.361	-0.680
	-0.634	-0.996	-0.181	0.239
Sample 2	-0.775	-1.421	-0.818	0.328
	0.213	1.425	-0.165	

- (a) Obtain *comparison boxplots* of these two samples. Comparison boxplots consist of boxplots of both samples drawn on the same scale. Based on these plots, in particular the interquartile ranges, what do you conclude about H_0 ?
- (b) Obtain the F -test (for a one-sided hypothesis) as discussed in Remark 8.3.2 at level $\alpha = 0.10$. What is your conclusion?
- (c) The test in part (b) is not exact. Why?

8.3.18. For the skewed contaminated normal random variable X of Example 8.3.4, derive the cdf, pdf, mean, and variance of X .

8.3.19. For Table 8.3.1 of Example 8.3.4, show that the half-width of the 95% confidence interval for a binomial proportion as given in Chapter 4 is 0.004 at the nominal value of 0.05.

8.3.20. If computational facilities are available, perform a Monte Carlo study of the two-sided t -test for the skewed contaminated normal situation of Example 8.3.4. The R function `rscn.R` generates variates from the distribution of X .

8.3.21. Suppose X_1, \dots, X_n is a random sample on X which has a $N(\mu, \sigma_0^2)$ distribution, where σ_0^2 is known. Consider the two-sided hypotheses

$$H_0 : \mu = 0 \text{ versus } H_1 : \mu \neq 0.$$

Show that the test based on the critical region $C = \{|\bar{X}| > \sqrt{\sigma_0^2/n}z_{\alpha/2}\}$ is an unbiased level α test.

8.3.22. Assume the same situation as in the last exercise but consider the test with critical region $C^* = \{\bar{X} > \sqrt{\sigma_0^2/n}z_\alpha\}$. Show that the test based on C^* has significance level α but that it is not an unbiased test.

8.4 *The Sequential Probability Ratio Test

Theorem 8.1.1 provides us with a method for determining a best critical region for testing a simple hypothesis against an alternative simple hypothesis. Recall its statement: Let X_1, X_2, \dots, X_n be a random sample with fixed sample size n from a distribution that has pdf or pmf $f(x; \theta)$, where $\theta = \{\theta : \theta = \theta', \theta''\}$ and θ' and θ''

are known numbers. For this section, we denote the likelihood of X_1, X_2, \dots, X_n by

$$L(\theta; n) = f(x_1; \theta)f(x_2; \theta) \cdots f(x_n; \theta),$$

a notation that reveals both the parameter θ and the sample size n . If we reject $H_0 : \theta = \theta'$ and accept $H_1 : \theta = \theta''$ when and only when

$$\frac{L(\theta'; n)}{L(\theta''; n)} \leq k,$$

where $k > 0$, then by Theorem 8.1.1 this is a best test of H_0 against H_1 .

Let us now suppose that the sample size n is *not* fixed in advance. In fact, let the sample size be a random variable N with sample space $\{1, 2, 3, \dots\}$. An interesting procedure for testing the simple hypothesis $H_0 : \theta = \theta'$ against the simple hypothesis $H_1 : \theta = \theta''$ is the following: Let k_0 and k_1 be two positive constants with $k_0 < k_1$. Observe the independent outcomes X_1, X_2, X_3, \dots in a sequence, for example, x_1, x_2, x_3, \dots , and compute

$$\frac{L(\theta'; 1)}{L(\theta''; 1)}, \frac{L(\theta'; 2)}{L(\theta''; 2)}, \frac{L(\theta'; 3)}{L(\theta''; 3)}, \dots$$

The hypothesis $H_0 : \theta = \theta'$ is rejected (and $H_1 : \theta = \theta''$ is accepted) if and only if there exists a positive integer n so that $\mathbf{x}_n = (x_1, x_2, \dots, x_n)$ belongs to the set

$$C_n = \left\{ \mathbf{x}_n : k_0 < \frac{L(\theta', j)}{L(\theta'', j)} < k_1, j = 1, \dots, n-1, \text{ and } \frac{L(\theta', n)}{L(\theta'', n)} \leq k_0 \right\}. \quad (8.4.1)$$

On the other hand, the hypothesis $H_0 : \theta = \theta'$ is accepted (and $H_1 : \theta = \theta''$ is rejected) if and only if there exists a positive integer n so that (x_1, x_2, \dots, x_n) belongs to the set

$$B_n = \left\{ \mathbf{x}_n : k_0 < \frac{L(\theta', j)}{L(\theta'', j)} < k_1, j = 1, \dots, n-1, \text{ and } \frac{L(\theta', n)}{L(\theta'', n)} \geq k_1 \right\}. \quad (8.4.2)$$

That is, we continue to observe sample observations as long as

$$k_0 < \frac{L(\theta', n)}{L(\theta'', n)} < k_1. \quad (8.4.3)$$

We stop these observations in one of two ways:

1. With rejection of $H_0 : \theta = \theta'$ as soon as

$$\frac{L(\theta', n)}{L(\theta'', n)} \leq k_0$$

or

2. With acceptance of $H_0 : \theta = \theta'$ as soon as

$$\frac{L(\theta', n)}{L(\theta'', n)} \geq k_1,$$

A test of this kind is called Wald's **sequential probability ratio test**. Frequently, inequality (8.4.3) can be conveniently expressed in an equivalent form:

$$c_0(n) < u(x_1, x_2, \dots, x_n) < c_1(n), \quad (8.4.4)$$

where $u(X_1, X_2, \dots, X_n)$ is a statistic and $c_0(n)$ and $c_1(n)$ depend on the constants $k_0, k_1, \theta', \theta''$, and on n . Then the observations are stopped and a decision is reached as soon as

$$u(x_1, x_2, \dots, x_n) \leq c_0(n) \quad \text{or} \quad u(x_1, x_2, \dots, x_n) \geq c_1(n).$$

We now give an illustrative example.

Example 8.4.1. Let X have a pmf

$$f(x; \theta) = \begin{cases} \theta^x (1 - \theta)^{1-x} & x = 0, 1 \\ 0 & \text{elsewhere.} \end{cases}$$

In the preceding discussion of a sequential probability ratio test, let $H_0 : \theta = \frac{1}{3}$ and $H_1 : \theta = \frac{2}{3}$; then, with $\sum x_i = \sum_{i=1}^n x_i$,

$$\frac{L(\frac{1}{3}, n)}{L(\frac{2}{3}, n)} = \frac{\left(\frac{1}{3}\right)^{\sum x_i} \left(\frac{2}{3}\right)^{n-\sum x_i}}{\left(\frac{2}{3}\right)^{\sum x_i} \left(\frac{1}{3}\right)^{n-\sum x_i}} = 2^{n-2\sum x_i}.$$

If we take logarithms to the base 2, the inequality

$$k_0 < \frac{L(\frac{1}{3}, n)}{L(\frac{2}{3}, n)} < k_1,$$

with $0 < k_0 < k_1$, becomes

$$\log_2 k_0 < n - 2 \sum_1^n x_i < \log_2 k_1,$$

or, equivalently, in the notation of expression (8.4.4),

$$c_0(n) = \frac{n}{2} - \frac{1}{2} \log_2 k_1 < \sum_1^n x_i < \frac{n}{2} - \frac{1}{2} \log_2 k_0 = c_1(n).$$

Note that $L(\frac{1}{3}, n)/L(\frac{2}{3}, n) \leq k_0$ if and only if $c_1(n) \leq \sum_1^n x_i$; and $L(\frac{1}{3}, n)/L(\frac{2}{3}, n) \geq k_1$ if and only if $c_0(n) \geq \sum_1^n x_i$. Thus we continue to observe outcomes as long as $c_0(n) < \sum_1^n x_i < c_1(n)$. The observation of outcomes is discontinued with the first value of n of N for which either $c_1(n) \leq \sum_1^n x_i$ or $c_0(n) \geq \sum_1^n x_i$. The inequality $c_1(n) \leq \sum_1^n x_i$ leads to rejection of $H_0 : \theta = \frac{1}{3}$ (the acceptance of H_1), and the inequality $c_0(n) \geq \sum_1^n x_i$ leads to the acceptance of $H_0 : \theta = \frac{1}{3}$ (the rejection of H_1). ■

Remark 8.4.1. At this point, the reader undoubtedly sees that there are many questions that should be raised in connection with the sequential probability ratio test. Some of these questions are possibly among the following:

1. What is the probability of the procedure continuing indefinitely?
2. What is the value of the power function of this test at each of the points $\theta = \theta'$ and $\theta = \theta''$?
3. If θ'' is one of several values of θ specified by an alternative composite hypothesis, say $H_1 : \theta > \theta'$, what is the power function at each point $\theta \geq \theta'$?
4. Since the sample size N is a random variable, what are some of the properties of the distribution of N ? In particular, what is the expected value $E(N)$ of N ?
5. How does this test compare with tests that have a fixed sample size n ? ■

A course in sequential analysis would investigate these and many other problems. However, in this book our objective is largely that of acquainting the reader with this kind of test procedure. Accordingly, we assert that the answer to question 1 is zero. Moreover, it can be proved that if $\theta = \theta'$ or if $\theta = \theta''$, $E(N)$ is smaller for this sequential procedure than the sample size of a fixed-sample-size test that has the same values of the power function at those points. We now consider question 2 in some detail.

In this section we shall denote the power of the test when H_0 is true by the symbol α and the power of the test when H_1 is true by the symbol $1 - \beta$. Thus α is the probability of committing a Type I error (the rejection of H_0 when H_0 is true), and β is the probability of committing a Type II error (the acceptance of H_0 when H_0 is false). With the sets C_n and B_n as previously defined, and with random variables of the continuous type, we then have

$$\alpha = \sum_{n=1}^{\infty} \int_{C_n} L(\theta', n), \quad 1 - \beta = \sum_{n=1}^{\infty} \int_{C_n} L(\theta'', n).$$

Since the probability is 1 that the procedure terminates, we also have

$$1 - \alpha = \sum_{n=1}^{\infty} \int_{B_n} L(\theta', n), \quad \beta = \sum_{n=1}^{\infty} \int_{B_n} L(\theta'', n).$$

If $(x_1, x_2, \dots, x_n) \in C_n$, we have $L(\theta', n) \leq k_0 L(\theta'', n)$; hence, it is clear that

$$\alpha = \sum_{n=1}^{\infty} \int_{C_n} L(\theta', n) \leq \sum_{n=1}^{\infty} \int_{C_n} k_0 L(\theta'', n) = k_0(1 - \beta).$$

Because $L(\theta', n) \geq k_1 L(\theta'', n)$ at each point of the set B_n , we have

$$1 - \alpha = \sum_{n=1}^{\infty} \int_{B_n} L(\theta', n) \geq \sum_{n=1}^{\infty} \int_{B_n} k_1 L(\theta'', n) = k_1 \beta.$$

Accordingly, it follows that

$$\frac{\alpha}{1 - \beta} \leq k_0, \quad k_1 \leq \frac{1 - \alpha}{\beta}, \tag{8.4.5}$$

provided that β is not equal to 0 or 1.

Now let α_a and β_a be preassigned proper fractions; some typical values in the applications are 0.01, 0.05, and 0.10. If we take

$$k_0 = \frac{\alpha_a}{1 - \beta_a}, \quad k_1 = \frac{1 - \alpha_a}{\beta_a},$$

then inequalities (8.4.5) become

$$\frac{\alpha}{1 - \beta} \leq \frac{\alpha_a}{1 - \beta_a}, \quad \frac{1 - \alpha_a}{\beta_a} \leq \frac{1 - \alpha}{\beta}; \quad (8.4.6)$$

or, equivalently,

$$\alpha(1 - \beta_a) \leq (1 - \beta)\alpha_a, \quad \beta(1 - \alpha_a) \leq (1 - \alpha)\beta_a.$$

If we add corresponding members of the immediately preceding inequalities, we find that

$$\alpha + \beta - \alpha\beta_a - \beta\alpha_a \leq \alpha_a + \beta_a - \beta\alpha_a - \alpha\beta_a$$

and hence

$$\alpha + \beta \leq \alpha_a + \beta_a;$$

that is, the sum $\alpha + \beta$ of the probabilities of the two kinds of errors is bounded above by the sum $\alpha_a + \beta_a$ of the preassigned numbers. Moreover, since α and β are positive proper fractions, inequalities (8.4.6) imply that

$$\alpha \leq \frac{\alpha_a}{1 - \beta_a}, \quad \beta \leq \frac{\beta_a}{1 - \alpha_a};$$

consequently, we have an upper bound on each of α and β . Various investigations of the sequential probability ratio test seem to indicate that in most practical cases, the values of α and β are quite close to α_a and β_a . This prompts us to approximate the power function at the points $\theta = \theta'$ and $\theta = \theta''$ by α_a and $1 - \beta_a$, respectively.

Example 8.4.2. Let X be $N(\theta, 100)$. To find the sequential probability ratio test for testing $H_0 : \theta = 75$ against $H_1 : \theta = 78$ such that each of α and β is approximately equal to 0.10, take

$$k_0 = \frac{0.10}{1 - 0.10} = \frac{1}{9}, \quad k_1 = \frac{1 - 0.10}{0.10} = 9.$$

Since

$$\frac{L(75, n)}{L(78, n)} = \frac{\exp[-\sum(x_i - 75)^2/2(100)]}{\exp[-\sum(x_i - 78)^2/2(100)]} = \exp\left(-\frac{6\sum x_i - 459n}{200}\right),$$

the inequality

$$k_0 = \frac{1}{9} < \frac{L(75, n)}{L(78, n)} < 9 = k_1$$

can be rewritten, by taking logarithms, as

$$-\log 9 < \frac{6 \sum x_i - 459n}{200} < \log 9.$$

This inequality is equivalent to the inequality

$$c_0(n) = \frac{153}{2}n - \frac{100}{3}\log 9 < \sum_1^n x_i < \frac{153}{2}n + \frac{100}{3}\log 9 = c_1(n).$$

Moreover, $L(75, n)/L(78, n) \leq k_0$ and $L(75, n)/L(78, n) \geq k_1$ are equivalent to the inequalities $\sum_1^n x_i \geq c_1(n)$ and $\sum_1^n x_i \leq c_0(n)$, respectively. Thus the observation of outcomes is discontinued with the first value of n of N for which either $\sum_1^n x_i \geq c_1(n)$ or $\sum_1^n x_i \leq c_0(n)$. The inequality $\sum_1^n x_i \geq c_1(n)$ leads to the rejection of $H_0 : \theta = 75$, and the inequality $\sum_1^n x_i \leq c_0(n)$ leads to the acceptance of $H_0 : \theta = 75$. The power of the test is approximately 0.10 when H_0 is true, and approximately 0.90 when H_1 is true. ■

Remark 8.4.2. It is interesting to note that a sequential probability ratio test can be thought of as a *random-walk procedure*. To illustrate, the final inequalities of Examples 8.4.1 and 8.4.2 can be written as

$$-\log_2 k_1 < \sum_1^n 2(x_i - 0.5) < -\log_2 k_0$$

and

$$-\frac{100}{3}\log 9 < \sum_1^n (x_i - 76.5) < \frac{100}{3}\log 9,$$

respectively. In each instance, think of starting at the point zero and taking random steps until one of the boundaries is reached. In the first situation the random steps are $2(X_1 - 0.5), 2(X_2 - 0.5), 2(X_3 - 0.5), \dots$, which have the same length, 1, but with random directions. In the second instance, both the length and the direction of the steps are random variables, $X_1 - 76.5, X_2 - 76.5, X_3 - 76.5, \dots$. ■

In recent years, there has been much attention devoted to improving quality of products using statistical methods. One such simple method was developed by Walter Shewhart in which a sample of size n of the items being produced is taken and they are measured, resulting in n values. The mean \bar{X} of these n measurements has an approximate normal distribution with mean μ and variance σ^2/n . In practice, μ and σ^2 must be estimated, but in this discussion, we assume that they are known. From theory we know that the probability is 0.997 that \bar{x} is between

$$\text{LCL} = \mu - \frac{3\sigma}{\sqrt{n}} \quad \text{and} \quad \text{UCL} = \mu + \frac{3\sigma}{\sqrt{n}}.$$

These two values are called the lower (LCL) and upper (UCL) control limits, respectively. Samples like these are taken periodically, resulting in a sequence of means,

say $\bar{x}_1, \bar{x}_2, \bar{x}_3, \dots$. These are usually plotted; and if they are between the LCL and UCL, we say that the process is **in control**. If one falls outside the limits, this would suggest that the mean μ has shifted, and the process would be investigated.

It was recognized by some that there could be a shift in the mean, say from μ to $\mu + (\sigma/\sqrt{n})$; and it would still be difficult to detect that shift with a single sample mean, for now the probability of a single \bar{x} exceeding UCL is only about 0.023. This means that we would need about $1/0.023 \approx 43$ samples, each of size n , on the average before detecting such a shift. This seems too long; so statisticians recognized that they should be cumulating experience as the sequence $\bar{X}_1, \bar{X}_2, \bar{X}_3, \dots$ is observed in order to help them detect the shift sooner. It is the practice to compute the standardized variable $Z = (\bar{X} - \mu)/(\sigma/\sqrt{n})$; thus, we state the problem in these terms and provide the solution given by a sequential probability ratio test.

Here Z is $N(\theta, 1)$, and we wish to test $H_0 : \theta = 0$ against $H_1 : \theta = 1$ using the sequence of iid random variables $Z_1, Z_2, \dots, Z_m, \dots$. We use m rather than n , as the latter is the size of the samples taken periodically. We have

$$\frac{L(0, m)}{L(1, m)} = \frac{\exp[-\sum z_i^2/2]}{\exp[-\sum(z_i - 1)^2/2]} = \exp\left[-\sum_{i=1}^m (z_i - 0.5)\right].$$

Thus

$$k_0 < \exp\left[-\sum_{i=1}^m (z_i - 0.5)\right] < k_1$$

can be written as

$$h = -\log k_0 > \sum_{i=1}^m (z_i - 0.5) > -\log k_1 = -h.$$

It is true that $-\log k_0 = \log k_1$ when $\alpha_a = \beta_a$. Often, $h = -\log k_0$ is taken to be about 4 or 5, suggesting that $\alpha_a = \beta_a$ is small, like 0.01. As $\sum(z_i - 0.5)$ is cumulating the sum of $z_i - 0.5$, $i = 1, 2, 3, \dots$, these procedures are often called CUSUMS. If the CUSUM $= \sum(z_i - 0.5)$ exceeds h , we would investigate the process, as it seems that the mean has shifted upward. If this shift is to $\theta = 1$, the theory associated with these procedures shows that we need only eight or nine samples on the average, rather than 43, to detect this shift. For more information about these methods, the reader is referred to one of the many books on quality improvement through statistical methods. What we would like to emphasize here is that through sequential methods (not only the sequential probability ratio test), we should take advantage of all past experience that we can gather in making inferences.

EXERCISES

8.4.1. Let X be $N(0, \theta)$ and, in the notation of this section, let $\theta' = 4$, $\theta'' = 9$, $\alpha_a = 0.05$, and $\beta_a = 0.10$. Show that the sequential probability ratio test can be based upon the statistic $\sum_1^n X_i^2$. Determine $c_0(n)$ and $c_1(n)$.

8.4.2. Let X have a Poisson distribution with mean θ . Find the sequential probability ratio test for testing $H_0 : \theta = 0.02$ against $H_1 : \theta = 0.07$. Show that this test can be based upon the statistic $\sum_1^n X_i$. If $\alpha_a = 0.20$ and $\beta_a = 0.10$, find $c_0(n)$ and $c_1(n)$.

8.4.3. Let the independent random variables Y and Z be $N(\mu_1, 1)$ and $N(\mu_2, 1)$, respectively. Let $\theta = \mu_1 - \mu_2$. Let us observe independent observations from each distribution, say Y_1, Y_2, \dots and Z_1, Z_2, \dots . To test sequentially the hypothesis $H_0 : \theta = 0$ against $H_1 : \theta = \frac{1}{2}$, use the sequence $X_i = Y_i - Z_i$, $i = 1, 2, \dots$. If $\alpha_a = \beta_a = 0.05$, show that the test can be based upon $\bar{X} = \bar{Y} - \bar{Z}$. Find $c_0(n)$ and $c_1(n)$.

8.4.4. Suppose that a manufacturing process makes about 3% defective items, which is considered satisfactory for this particular product. The managers would like to decrease this to about 1% and clearly want to guard against a substantial increase, say to 5%. To monitor the process, periodically $n = 100$ items are taken and the number X of defectives counted. Assume that X is $b(n = 100, p = \theta)$. Based on a sequence $X_1, X_2, \dots, X_m, \dots$, determine a sequential probability ratio test that tests $H_0 : \theta = 0.01$ against $H_1 : \theta = 0.05$. (Note that $\theta = 0.03$, the present level, is in between these two values.) Write this test in the form

$$h_0 > \sum_{i=1}^m (x_i - nd) > h_1$$

and determine d , h_0 , and h_1 if $\alpha_a = \beta_a = 0.02$.

8.4.5. Let X_1, X_2, \dots, X_n be a random sample from a distribution with pdf $f(x; \theta) = \theta x^{\theta-1}$, $0 < x < 1$, zero elsewhere.

- (a) Find a complete sufficient statistic for θ .
- (b) If $\alpha_a = \beta_a = \frac{1}{10}$, find the sequential probability ratio test of $H_0 : \theta = 2$ against $H_1 : \theta = 3$.

8.5 *Minimax and Classification Procedures

We have considered several procedures that may be used in problems of point estimation. Among these were decision function procedures (in particular, minimax decisions). In this section, we apply minimax procedures to the problem of testing a simple hypothesis H_0 against an alternative simple hypothesis H_1 . It is important to observe that these procedures yield, in accordance with the Neyman–Pearson theorem, a best test of H_0 against H_1 . We end this section with a discussion on an application of these procedures to a classification problem.

8.5.1 Minimax Procedures

We first investigate the decision function approach to the problem of testing a simple null hypothesis against a simple alternative hypothesis. Let the joint pdf of the n

random variables X_1, X_2, \dots, X_n depend upon the parameter θ . Here n is a fixed positive integer. This pdf is denoted by $L(\theta; x_1, x_2, \dots, x_n)$ or, for brevity, by $L(\theta)$. Let θ' and θ'' be distinct and fixed values of θ . We wish to test the simple hypothesis $H_0 : \theta = \theta'$ against the simple hypothesis $H_1 : \theta = \theta''$. Thus the parameter space is $\Omega = \{\theta : \theta = \theta', \theta''\}$. In accordance with the decision function procedure, we need a function δ of the observed values of X_1, \dots, X_n (or, of the observed value of a statistic Y) that decides which of the two values of θ , θ' or θ'' , to accept. That is, the function δ selects either $H_0 : \theta = \theta'$ or $H_1 : \theta = \theta''$. We denote these decisions by $\delta = \theta'$ and $\delta = \theta''$, respectively. Let $\mathcal{L}(\theta, \delta)$ represent the loss function associated with this decision problem. Because the pairs $(\theta = \theta', \delta = \theta')$ and $(\theta = \theta'', \delta = \theta'')$ represent correct decisions, we shall always take $\mathcal{L}(\theta', \theta') = \mathcal{L}(\theta'', \theta'') = 0$. On the other hand, if either $\delta = \theta''$ when $\theta = \theta'$ or $\delta = \theta'$ when $\theta = \theta''$, then a positive value should be assigned to the loss function; that is, $\mathcal{L}(\theta', \theta'') > 0$ and $\mathcal{L}(\theta'', \theta') > 0$.

It has previously been emphasized that a test of $H_0 : \theta = \theta'$ against $H_1 : \theta = \theta''$ can be described in terms of a critical region in the sample space. We can do the same kind of thing with the decision function. That is, we can choose a subset of C of the sample space and if $(x_1, x_2, \dots, x_n) \in C$, we can make the decision $\delta = \theta''$; whereas if $(x_1, x_2, \dots, x_n) \in C^c$, the complement of C , we make the decision $\delta = \theta'$. Thus a given critical region C determines the decision function. In this sense, we may denote the risk function by $R(\theta, C)$ instead of $R(\theta, \delta)$. That is, in a notation used in Section 7.1,

$$R(\theta, C) = R(\theta, \delta) = \int_{C \cup C^c} \mathcal{L}(\theta, \delta) L(\theta).$$

Since $\delta = \theta''$ if $(x_1, \dots, x_n) \in C$ and $\delta = \theta'$ if $(x_1, \dots, x_n) \in C^c$, we have

$$R(\theta, C) = \int_C \mathcal{L}(\theta, \theta'') L(\theta) + \int_{C^c} \mathcal{L}(\theta, \theta') L(\theta). \quad (8.5.1)$$

If, in Equation (8.5.1), we take $\theta = \theta'$, then $\mathcal{L}(\theta', \theta') = 0$ and hence

$$R(\theta', C) = \int_C \mathcal{L}(\theta', \theta'') L(\theta') = \mathcal{L}(\theta', \theta'') \int_C L(\theta').$$

On the other hand, if in Equation (8.5.1) we let $\theta = \theta''$, then $\mathcal{L}(\theta'', \theta'') = 0$ and, accordingly,

$$R(\theta'', C) = \int_{C^c} \mathcal{L}(\theta'', \theta') L(\theta'') = \mathcal{L}(\theta'', \theta') \int_{C^c} L(\theta'').$$

It is enlightening to note that if $\gamma(\theta)$ is the power function of the test associated with the critical region C , then

$$R(\theta', C) = \mathcal{L}(\theta', \theta'') \gamma(\theta') = \mathcal{L}(\theta', \theta'') \alpha,$$

where $\alpha = \gamma(\theta')$ is the significance level; and

$$R(\theta'', C) = \mathcal{L}(\theta'', \theta') [1 - \gamma(\theta'')] = \mathcal{L}(\theta'', \theta') \beta,$$

where $\beta = 1 - \gamma(\theta'')$ is the probability of the type II error.

Let us now see if we can find a minimax solution to our problem. That is, we want to find a critical region C so that

$$\max[R(\theta', C), R(\theta'', C)]$$

is minimized. We shall show that the solution is the region

$$C = \left\{ (x_1, \dots, x_n) : \frac{L(\theta'; x_1, \dots, x_n)}{L(\theta''; x_1, \dots, x_n)} \leq k \right\},$$

provided the positive constant k is selected so that $R(\theta', C) = R(\theta'', C)$. That is, if k is chosen so that

$$\mathcal{L}(\theta', \theta'') \int_C L(\theta') = \mathcal{L}(\theta'', \theta') \int_{C^c} L(\theta''),$$

then the critical region C provides a minimax solution. In the case of random variables of the continuous type, k can always be selected so that $R(\theta', C) = R(\theta'', C)$. However, with random variables of the discrete type, we may need to consider an auxiliary random experiment when $L(\theta')/L(\theta'') = k$ in order to achieve the exact equality $R(\theta', C) = R(\theta'', C)$.

To see that C is the minimax solution, consider every other region A for which $R(\theta', C) \geq R(\theta', A)$. A region A for which $R(\theta', C) < R(\theta', A)$ is not a candidate for a minimax solution, for then $R(\theta', C) = R(\theta'', C) < \max[R(\theta', A), R(\theta'', A)]$. Since $R(\theta', C) \geq R(\theta', A)$ means that

$$\mathcal{L}(\theta', \theta'') \int_C L(\theta') \geq \mathcal{L}(\theta', \theta'') \int_A L(\theta'),$$

we have

$$\alpha = \int_C L(\theta') \geq \int_A L(\theta');$$

that is, the significance level of the test associated with the critical region A is less than or equal to α . But C , in accordance with the Neyman–Pearson theorem, is a best critical region of size α . Thus

$$\int_C L(\theta'') \geq \int_A L(\theta'')$$

and

$$\int_{C^c} L(\theta'') \leq \int_{A^c} L(\theta'').$$

Accordingly,

$$\mathcal{L}(\theta'', \theta') \int_{C^c} L(\theta'') \leq \mathcal{L}(\theta'', \theta') \int_{A^c} L(\theta''),$$

or, equivalently,

$$R(\theta'', C) \leq R(\theta'', A).$$

That is,

$$R(\theta', C) = R(\theta'', C) \leq R(\theta'', A).$$

This means that

$$\max[R(\theta', C), R(\theta'', C)] \leq R(\theta'', A).$$

Then certainly,

$$\max[R(\theta', C), R(\theta'', C)] \leq \max[R(\theta', A), R(\theta'', A)],$$

and the critical region C provides a minimax solution, as we wanted to show.

Example 8.5.1. Let X_1, X_2, \dots, X_{100} denote a random sample of size 100 from a distribution that is $N(\theta, 100)$. We again consider the problem of testing $H_0 : \theta = 75$ against $H_1 : \theta = 78$. We seek a minimax solution with $\mathcal{L}(75, 78) = 3$ and $\mathcal{L}(78, 75) = 1$. Since $L(75)/L(78) \leq k$ is equivalent to $\bar{x} \geq c$, we want to determine c , and thus k , so that

$$3P(\bar{X} \geq c; \theta = 75) = P(\bar{X} < c; \theta = 78). \quad (8.5.2)$$

Because \bar{X} is $N(\theta, 1)$, the preceding equation can be rewritten as

$$3[1 - \Phi(c - 75)] = \Phi(c - 78).$$

As requested in Exercise 8.5.4, the reader can show by using Newton's algorithm that the solution to one place is $c = 76.8$. The significance level of the test is $1 - \Phi(1.8) = 0.036$, approximately, and the power of the test when H_1 is true is $1 - \Phi(-1.2) = 0.885$, approximately. ■

8.5.2 Classification

The summary above has an interesting application to the problem of **classification**, which can be described as follows. An investigator makes a number of measurements on an item and wants to place it into one of several categories (or classify it). For convenience in our discussion, we assume that only two measurements, say X and Y , are made on the item to be classified. Moreover, let X and Y have a joint pdf $f(x, y; \theta)$, where the parameter θ represents one or more parameters. In our simplification, suppose that there are only two possible joint distributions (categories) for X and Y , which are indexed by the parameter values θ' and θ'' , respectively. In this case, the problem then reduces to one of observing $X = x$ and $Y = y$ and then testing the hypothesis $\theta = \theta'$ against the hypothesis $\theta = \theta''$, with the classification of X and Y being in accord with which hypothesis is accepted. From the Neyman–Pearson theorem, we know that a best decision of this sort is of the following form: If

$$\frac{f(x, y; \theta')}{f(x, y; \theta'')} \leq k,$$

choose the distribution indexed by θ'' ; that is, we classify (x, y) as coming from the distribution indexed by θ'' . Otherwise, choose the distribution indexed by θ' ; that is, we classify (x, y) as coming from the distribution indexed by θ' . Some discussion on the choice of k follows in the next remark.

Remark 8.5.1 (On the Choice of k). Consider the following probabilities:

$$\begin{aligned}\pi' &= P[(X, Y) \text{ is drawn from the distribution with pdf } f(x, y; \theta')] \\ \pi'' &= P[(X, Y) \text{ is drawn from the distribution with pdf } f(x, y; \theta'')].\end{aligned}$$

Note that $\pi' + \pi'' = 1$. Then it can be shown that the optimal classification rule is determined by taking $k = \pi''/\pi'$; see, for instance, Seber (1984). Hence, if we have prior information on how likely the item is drawn from the distribution with parameter θ' , then we can obtain the classification rule. In practice, it is common for each distribution to be equilike, in which case, $\pi' = \pi'' = 1/2$ and, hence, $k = 1$. ■

Example 8.5.2. Let (x, y) be an observation of the random pair (X, Y) , which has a bivariate normal distribution with parameters $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$, and ρ . In Section 3.5 that joint pdf is given by

$$f(x, y; \mu_1, \mu_2, \sigma_1^2, \sigma_2^2) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} e^{-q(x, y; \mu_1, \mu_2)/2},$$

for $-\infty < x < \infty$ and $-\infty < y < \infty$, where $\sigma_1 > 0, \sigma_2 > 0, -1 < \rho < 1$, and

$$q(x, y; \mu_1, \mu_2) = \frac{1}{1-\rho^2} \left[\left(\frac{x-\mu_1}{\sigma_1} \right)^2 - 2\rho \left(\frac{x-\mu_1}{\sigma_1} \right) \left(\frac{y-\mu_2}{\sigma_2} \right) + \left(\frac{y-\mu_2}{\sigma_2} \right)^2 \right].$$

Assume that σ_1^2, σ_2^2 , and ρ are known but that we do not know whether the respective means of (X, Y) are (μ'_1, μ'_2) or (μ''_1, μ''_2) . The inequality

$$\frac{f(x, y; \mu'_1, \mu'_2, \sigma_1^2, \sigma_2^2, \rho)}{f(x, y; \mu''_1, \mu''_2, \sigma_1^2, \sigma_2^2, \rho)} \leq k$$

is equivalent to

$$\frac{1}{2}[q(x, y; \mu''_1, \mu''_2) - q(x, y; \mu'_1, \mu'_2)] \leq \log k.$$

Moreover, it is clear that the difference in the left-hand member of this inequality does not contain terms involving x^2, xy , and y^2 . In particular, this inequality is the same as

$$\begin{aligned}\frac{1}{1-\rho^2} \left\{ \left[\frac{\mu'_1 - \mu''_1}{\sigma_1^2} - \frac{\rho(\mu'_2 - \mu''_2)}{\sigma_1\sigma_2} \right] x + \left[\frac{\mu'_2 - \mu''_2}{\sigma_2^2} - \frac{\rho(\mu'_1 - \mu''_1)}{\sigma_1\sigma_2} \right] y \right\} \\ \leq \log k + \frac{1}{2}[q(0, 0; \mu'_1, \mu'_2) - q(0, 0; \mu''_1, \mu''_2)],\end{aligned}$$

or, for brevity,

$$ax + by \leq c. \quad (8.5.3)$$

That is, if this linear function of x and y in the left-hand member of inequality (8.5.3) is less than or equal to a constant, we classify (x, y) as coming from the bivariate normal distribution with means μ_1'' and μ_2'' . Otherwise, we classify (x, y) as arising from the bivariate normal distribution with means μ_1' and μ_2' . Of course, if the prior probabilities can be assigned as discussed in Remark 8.5.1 then k and thus c can be found easily; see Exercise 8.5.3. ■

Once the rule for classification is established, the statistician might be interested in the two probabilities of misclassifications using that rule. The first of these two is associated with the classification of (x, y) as arising from the distribution indexed by θ'' if, in fact, it comes from that index by θ' . The second misclassification is similar, but with the interchange of θ' and θ'' . In the preceding example, the probabilities of these respective misclassifications are

$$P(aX + bY \leq c; \mu_1', \mu_2') \quad \text{and} \quad P(aX + bY > c; \mu_1'', \mu_2'').$$

The distribution of $Z = aX + bY$ is obtained from Theorem 3.5.2. It follows that the distribution of $Z = aX + bY$ is given by

$$N(a\mu_1 + b\mu_2, a^2\sigma_1^2 + 2ab\rho\sigma_1\sigma_2 + b^2\sigma_2^2).$$

With this information, it is easy to compute the probabilities of misclassifications; see Exercise 8.5.3.

One final remark must be made with respect to the use of the important classification rule established in Example 8.5.2. In most instances the parameter values μ_1', μ_2' and μ_1'', μ_2'' as well as σ_1^2, σ_2^2 , and ρ are unknown. In such cases the statistician has usually observed a random sample (frequently called a *training sample*) from each of the two distributions. Let us say the samples have sizes n' and n'' , respectively, with sample characteristics

$$\bar{x}', \bar{y}', (s'_x)^2, (s'_y)^2, r' \quad \text{and} \quad \bar{x}'', \bar{y}'', (s''_x)^2, (s''_y)^2, r''.$$

The statistics r' and r'' are the sample correlation coefficients, as defined in expression (9.7.1) of Section 9.7. The sample correlation coefficient is the mle for the correlation parameter ρ of a bivariate normal distribution; see Section 9.7. If in inequality (8.5.3) the parameters $\mu_1', \mu_2', \mu_1'', \mu_2'', \sigma_1^2, \sigma_2^2$, and $\rho\sigma_1\sigma_2$ are replaced by the unbiased estimates

$$\bar{x}', \bar{y}', \bar{x}'', \bar{y}'', \frac{(n' - 1)(s'_x)^2 + (n'' - 1)(s''_x)^2}{n' + n'' - 2}, \frac{(n' - 1)(s'_y)^2 + (n'' - 1)(s''_y)^2}{n' + n'' - 2}, \\ \frac{(n' - 1)r's'_x s'_y + (n'' - 1)r''s''_x s''_y}{n' + n'' - 2},$$

the resulting expression in the left-hand member is frequently called Fisher's **linear discriminant function**. Since those parameters have been estimated, the distribution theory associated with $aX + bY$ does provide an approximation.

Although we have considered only bivariate distributions in this section, the results can easily be extended to multivariate normal distributions using the results of Section 3.5; see also Chapter 6 of Seber (1984).

EXERCISES

8.5.1. Let X_1, X_2, \dots, X_{20} be a random sample of size 20 from a distribution that is $N(\theta, 5)$. Let $L(\theta)$ represent the joint pdf of X_1, X_2, \dots, X_{20} . The problem is to test $H_0 : \theta = 1$ against $H_1 : \theta = 0$. Thus $\Omega = \{\theta : \theta = 0, 1\}$.

- (a) Show that $L(1)/L(0) \leq k$ is equivalent to $\bar{x} \leq c$.
- (b) Find c so that the significance level is $\alpha = 0.05$. Compute the power of this test if H_1 is true.
- (c) If the loss function is such that $\mathcal{L}(1, 1) = \mathcal{L}(0, 0) = 0$ and $\mathcal{L}(1, 0) = \mathcal{L}(0, 1) > 0$, find the minimax test. Evaluate the power function of this test at the points $\theta = 1$ and $\theta = 0$.

8.5.2. Let X_1, X_2, \dots, X_{10} be a random sample of size 10 from a Poisson distribution with parameter θ . Let $L(\theta)$ be the joint pdf of X_1, X_2, \dots, X_{10} . The problem is to test $H_0 : \theta = \frac{1}{2}$ against $H_1 : \theta = 1$.

- (a) Show that $L(\frac{1}{2})/L(1) \leq k$ is equivalent to $y = \sum_1^n x_i \geq c$.
- (b) In order to make $\alpha = 0.05$, show that H_0 is rejected if $y > 9$ and, if $y = 9$, reject H_0 with probability $\frac{1}{2}$ (using some auxiliary random experiment).
- (c) If the loss function is such that $\mathcal{L}(\frac{1}{2}, \frac{1}{2}) = \mathcal{L}(1, 1) = 0$ and $\mathcal{L}(\frac{1}{2}, 1) = 1$ and $\mathcal{L}(1, \frac{1}{2}) = 2$, show that the minimax procedure is to reject H_0 if $y > 6$ and, if $y = 6$, reject H_0 with probability 0.08 (using some auxiliary random experiment).

8.5.3. In Example 8.5.2 let $\mu'_1 = \mu'_2 = 0$, $\mu''_1 = \mu''_2 = 1$, $\sigma_1^2 = 1$, $\sigma_2^2 = 1$, and $\rho = \frac{1}{2}$.

- (a) Find the distribution of the linear function $aX + bY$.
- (b) With $k = 1$, compute $P(aX + bY \leq c; \mu'_1 = \mu'_2 = 0)$ and $P(aX + bY > c; \mu''_1 = \mu''_2 = 1)$.

8.5.4. Determine Newton's algorithm to find the solution of Equation (8.5.2). If software is available, write a program that performs your algorithm and then show that the solution is $c = 76.8$. If software is not available, solve (8.5.2) by "trial and error."

8.5.5. Let X and Y have the joint pdf

$$f(x, y; \theta_1, \theta_2) = \frac{1}{\theta_1 \theta_2} \exp\left(-\frac{x}{\theta_1} - \frac{y}{\theta_2}\right), \quad 0 < x < \infty, \quad 0 < y < \infty,$$

zero elsewhere, where $0 < \theta_1$, $0 < \theta_2$. An observation (x, y) arises from the joint distribution with parameters equal to either $(\theta'_1 = 1, \theta'_2 = 5)$ or $(\theta''_1 = 3, \theta''_2 = 2)$. Determine the form of the classification rule.

8.5.6. Let X and Y have a joint bivariate normal distribution. An observation (x, y) arises from the joint distribution with parameters equal to either

$$\mu'_1 = \mu'_2 = 0, \quad (\sigma_1^2)' = (\sigma_2^2)' = 1, \quad \rho' = \frac{1}{2}$$

or

$$\mu''_1 = \mu''_2 = 1, \quad (\sigma_1^2)'' = 4, \quad (\sigma_2^2)'' = 9, \quad \rho'' = \frac{1}{2}.$$

Show that the classification rule involves a second-degree polynomial in x and y .

8.5.7. Let $\mathbf{W}' = (W_1, W_2)$ be an observation from one of two bivariate normal distributions, I and II, each with $\mu_1 = \mu_2 = 0$ but with the respective variance-covariance matrices

$$\mathbf{V}_1 = \begin{pmatrix} 1 & 0 \\ 0 & 4 \end{pmatrix} \quad \text{and} \quad \mathbf{V}_2 = \begin{pmatrix} 3 & 0 \\ 0 & 12 \end{pmatrix}.$$

How would you classify \mathbf{W} into I or II?

Chapter 9

Inferences About Normal Linear Models

9.1 Introduction

In this chapter, we consider analyses of some of the most widely used linear models. These models include one- and two-way analysis of variance (ANOVA) models and regression and correlation models. We generally assume normally distributed random errors for these models. The inference procedures that we discuss are, for the most part, based on maximum likelihood procedures. The theory requires some discussion of quadratic forms which we briefly introduce next.

Consider polynomials of degree 2 in n variables, X_1, \dots, X_n , of the form

$$q(X_1, \dots, X_n) = \sum_{i=1}^n \sum_{j=1}^n X_i a_{ij} X_j,$$

for n^2 constants a_{ij} . We call this form a **quadratic form** in the variables X_1, \dots, X_n . If both the variables and the coefficients are real, it is called a **real quadratic form**. Only real quadratic forms are considered in this book. To illustrate, the form $X_1^2 + X_1 X_2 + X_2^2$ is a quadratic form in the two variables X_1 and X_2 ; the form $X_1^2 + X_2^2 + X_3^2 - 2X_1 X_2$ is a quadratic form in the three variables X_1 , X_2 , and X_3 ; but the form $(X_1 - 1)^2 + (X_2 - 2)^2 = X_1^2 + X_2^2 - 2X_1 - 4X_2 + 5$ is not a quadratic form in X_1 and X_2 , although it is a quadratic form in the variables $X_1 - 1$ and $X_2 - 2$.

Let \bar{X} and S^2 denote, respectively, the mean and variance of a random sample

X_1, X_2, \dots, X_n from an arbitrary distribution. Thus

$$\begin{aligned}
(n-1)S^2 &= \sum_{i=1}^n (X_i - \bar{X})^2 = \sum_{i=1}^n X_i^2 - n\bar{X}^2 \\
&= \sum_{i=1}^n X_i^2 - \frac{n}{n^2} \left(\sum_{i=1}^n X_i \right)^2 \\
&= \sum_{i=1}^n X_i^2 - \frac{1}{n} \left(\sum_{i=1}^n X_i \sum_{j=1}^n X_j \right) \\
&= \sum_{i=1}^n X_i^2 - \frac{1}{n} \left(\sum_{i=1}^n X_i^2 + 2 \sum_{i < j} X_i X_j \right) \\
&= \frac{n-1}{n} \sum_{i=1}^n X_i^2 - \frac{2}{n} \sum_{i < j} X_i X_j.
\end{aligned}$$

So the sample variance is a quadratic form in the variables X_1, \dots, X_n .

9.2 One-Way ANOVA

Consider b independent random variables that have normal distributions with unknown means $\mu_1, \mu_2, \dots, \mu_b$, respectively, and unknown but common variance σ^2 . For each $j = 1, 2, \dots, b$, let $X_{1j}, X_{2j}, \dots, X_{nj}$ represent a random sample of size n_j from the normal distribution with mean μ_j and variance σ^2 . The appropriate model for the observations is

$$X_{ij} = \mu_j + e_{ij}; \quad i = 1, \dots, n_j, \quad j = 1, \dots, b, \quad (9.2.1)$$

where e_{ij} are iid $N(0, \sigma^2)$. Let $n = \sum_{j=1}^b n_j$ denote the total sample size. Suppose that it is desired to test the composite hypothesis

$$H_0 : \mu_1 = \mu_2 = \dots = \mu_b \text{ versus } H_1 : \mu_j \neq \mu_{j'}, \text{ for some } j \neq j'. \quad (9.2.2)$$

We derive the likelihood ratio test for these hypotheses.

Such problems often arise in practice. For example, suppose for a certain type of disease there are b drugs that can be used to treat it and we are interested in determining which drug is best in terms of a certain response. Let X_j denote this response when drug j is applied and let $\mu_j = E(X_j)$. If we assume that X_j is $N(\mu_j, \sigma^2)$, then the above null hypothesis says that all the drugs are equally effective; see Exercise 9.2.6 for a numerical illustration of this situation involving drugs that are intended to lower cholesterol. In general, we often summarize this problem by saying that we have one factor at b levels. In this case the factor is the treatment of the disease and each level corresponds to one of the treatment drugs.

Model (9.2.1) is called a **one-way** model. As shown, the likelihood ratio test can be thought of in terms of estimates of variance. Hence, this is an example of an

analysis of variance (ANOVA). In short, we say that this example is a one-way ANOVA problem.

Here the **full model** parameter space is

$$\Omega = \{(\mu_1, \mu_2, \dots, \mu_b, \sigma^2) : -\infty < \mu_j < \infty, 0 < \sigma^2 < \infty\},$$

while the **reduced model** (full model under H_0) parameter space is

$$\omega = \{(\mu_1, \mu_2, \dots, \mu_b, \sigma^2) : -\infty < \mu_1 = \mu_2 = \dots = \mu_b = \mu < \infty, 0 < \sigma^2 < \infty\}.$$

The likelihood functions, denoted by $L(\Omega)$ and $L(\omega)$ are, respectively,

$$L(\Omega) = \left(\frac{1}{2\pi\sigma^2} \right)^{ab/2} \exp \left[-\frac{1}{2\sigma^2} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \mu_j)^2 \right].$$

and

$$L(\omega) = \left(\frac{1}{2\pi\sigma^2} \right)^{ab/2} \exp \left[-\frac{1}{2\sigma^2} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \mu)^2 \right]$$

We first consider the reduced model. Notice that it is just a one sample model with sample size n from a $N(\mu, \sigma^2)$ distribution. We have derived the mles in Example 4.1.3 of Chapter 4, which, in this notation, are given by

$$\hat{\mu}_\omega = \frac{1}{n} \sum_{j=1}^b \sum_{i=1}^{n_j} x_{ij} = \bar{x}_{..} \quad \text{and} \quad \hat{\sigma}_\omega^2 = \frac{1}{n} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{..})^2. \quad (9.2.3)$$

The notation $\bar{x}_{..}$ denotes that the mean is taken over both subscripts. This is often called the **grand mean**. Evaluating $L(\omega)$ at the mles, we obtain after simplification:

$$L(\hat{\omega}) = \left(\frac{1}{2\pi} \right)^{n/2} \left(\frac{1}{\hat{\sigma}_\omega^2} \right)^{n/2} e^{-n/2}. \quad (9.2.4)$$

Next, we consider the full model. The log of its likelihood is

$$\log L(\Omega) = -(n/2) \log(2\pi) - (n/2) \log(\sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \mu_j)^2. \quad (9.2.5)$$

For $j = 1, \dots, b$, the partial of the log of $L(\Omega)$ with respect to μ_j results in

$$\frac{\partial \log L(\Omega)}{\partial \mu_j} = \frac{1}{\sigma^2} \sum_{i=1}^{n_j} (x_{ij} - \mu_j).$$

Setting this partial to 0 and solving for μ_j , we obtain the mle of μ_j which we denote by

$$\hat{\mu}_j = \frac{1}{n_j} \sum_{i=1}^{n_j} x_{ij} = \bar{x}_{.j}, \quad j = 1, \dots, b. \quad (9.2.6)$$

Since this derivation did not depend on σ , to find the mle of σ , we substitute $\bar{x}_{\cdot j}$ for μ_j in the log $L(\Omega)$. Taking the partial derivative with respect to σ we then get

$$\frac{\partial \log L(\Omega)}{\partial \sigma} = -(n/2) \frac{2\sigma}{\sigma^2} + \frac{1}{\sigma^3} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{\cdot j})^2.$$

Solving this for σ^2 , we obtain¹ the mle

$$\hat{\sigma}_\Omega^2 = \frac{1}{n} \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{\cdot j})^2. \quad (9.2.7)$$

Substituting these mles for their respective parameters in $L(\Omega)$, after some simplification, leads to

$$L(\hat{\Omega}) = \left(\frac{1}{2\pi} \right)^{n/2} \left(\frac{1}{\hat{\sigma}_\Omega^2} \right)^{n/2} e^{-n/2}. \quad (9.2.8)$$

Hence, the likelihood ratio test rejects H_0 in favor of H_1 for small values of the statistic $\hat{\Lambda} = L(\hat{\omega})/L(\hat{\Omega})$ or equivalently, for large values of $\hat{\Lambda}^{-2/n}$. We can express this test statistic as a ratio of two quadratic forms Q_3 and Q as

$$\begin{aligned} \hat{\Lambda}^{n/2} &= \frac{\hat{\sigma}_\Omega^2}{\hat{\sigma}_\omega^2} = \frac{\sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{\cdot j})^2}{\sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{..})^2} \\ &= \text{dfn } \frac{Q_3}{Q}. \end{aligned} \quad (9.2.9)$$

In order to rewrite the test statistic in terms of an F -statistic, consider the identity involving Q , Q_3 , and another quadratic form Q_4 given by:

$$\begin{aligned} Q &= \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{..})^2 = \sum_{j=1}^b \sum_{i=1}^{n_j} [(x_{ij} - \bar{x}_{\cdot j}) + (\bar{x}_{\cdot j} - \bar{x}_{..})]^2 \\ &= \sum_{j=1}^b \sum_{i=1}^{n_j} (x_{ij} - \bar{x}_{\cdot j})^2 + \sum_{j=1}^b n_j (\bar{x}_{\cdot j} - \bar{x}_{..})^2 \\ &= \text{dfn } Q_3 + Q_4. \end{aligned} \quad (9.2.10)$$

This derivation follows because the cross product term in the second line is 0. Using this identity, the test statistic $\hat{\Lambda}^{-2/n}$ can be expressed as

$$\hat{\Lambda}^{-2/n} = \frac{Q_3 + Q_4}{Q_3} = 1 + \frac{Q_4}{Q_3}.$$

As the final version, note that the test rejects H_0 if F is too large where

$$F = \frac{Q_4/(b-1)}{Q_3/(n-b)}. \quad (9.2.11)$$

¹We are using the fact that the mle of σ^2 is the square of the mle of σ .

To complete the test, we need to determine the distribution of F under H_0 . First consider the sum of squares in the denominator, Q_3 , which we write as:

$$Q_3/\sigma^2 = \sum_{j=1}^b \left\{ \frac{1}{\sigma^2} \sum_{i=1}^{n_j} (X_{ij} - \bar{X}_{.j})^2 \right\}.$$

Notice, since we are discussing distributions, we are now using random variable notation. By Part (c) of Theorem 3.6.1, for $j = 1, \dots, b$, the term within the braces has a χ^2 -distribution with $n_j - 1$ degrees of freedom. Further, the samples are independent so these χ^2 random variables are independent. Hence, by Corollary 3.3.1, Q_3/σ^2 has a χ^2 -distribution with $\sum_{j=1}^b (n_j - 1) = n - b$ degrees of freedom. By Part (b) of Theorem 3.6.1, the random variable $\bar{X}_{.j}$ is independent of the sum of squares within the braces and further, by the independence of the samples, it is independent of Q_3 . Thus, all b sample means are independent of Q_3 . Because $\bar{X}_{..} = \sum_{j=1}^b n_j \bar{X}_{.j}$, the grand mean $\bar{X}_{..}$ is a function of the b sample means, it must be independent of Q_3 , also. Therefore, Q_4 is independent of Q_3 . For the distribution of the numerator sum of squares, write the identity (9.2.10) as

$$Q/\sigma^2 = Q_3/\sigma^2 + Q_4/\sigma^2.$$

For the left side, under H_0 , Q/σ^2 has a χ^2 -distribution with $n - 1$ degrees of freedom. On the right side Q_3/σ^2 has a χ^2 -distribution with $n - b$ degrees of freedom and it is also independent of Q_4/σ^2 . By equating the mgfs of both sides, it follows that Q_4/σ^2 has a χ^2 -distribution with $(n - 1) - (n - b) = b - 1$ degrees of freedom. Therefore, under H_0 , the F test statistic, (9.2.11), has a F -distribution with $b - 1$ and $n - b$ degrees of freedom.

Suppose now that we wish to compute the power of the test of H_0 against H_1 when H_0 is false, that is, when we do not have $\mu_1 = \mu_2 = \dots = \mu_b$. In Section 9.3 we show that under H_1 , Q_4/σ^2 no longer has a $\chi^2(b - 1)$ distribution. Thus we cannot use an F -statistic to compute the power of the test when H_1 is true. The problem is discussed in Section 9.3.

Next, based on a simple example, we illustrate the computation of the F -test using R.

Example 9.2.1. Devore (2012), page 412, presents a data set where the response is the elastic modulus for an alloy that is cast by one of three different casting processes. The null hypothesis is that the mean of the elastic modulus is not affected by the casting process. The data are:

Cast Method	Elastic Modulus							
Permanent mold	45.5	45.3	45.4	44.4	44.6	43.9	44.6	44.0
Die cast	44.2	43.9	44.7	44.2	44.0	43.8	44.6	43.1
Plaster mold	46.0	45.9	44.8	46.2	45.1	45.5		

The data are in the file `elasticmod.rda`. The variable `elasticmod` contains the response while the variable `ind` contains the casting method (1, 2, or 3). The R code and results (test statistic F and the p -value) are:

```
oneway.test(elasticmod~ind, var.equal=T)
F = 12.565, num df = 2, denom df = 19, p-value = 0.0003336
```

With such a low p -value, the null hypothesis would be rejected and we would conclude that the casting method does have an effect on the elastic modulus. ■

In this example, the experimenter would also be interested in the pairwise comparisons of the casting methods. We consider this in Section 9.4.

EXERCISES

9.2.1. Consider the T -statistic that was derived through a likelihood ratio for testing the equality of the means of two normal distributions having common variance in Example 8.3.1. Show that T^2 is exactly the F -statistic of expression (9.2.11).

9.2.2. Under Model (9.2.1), show that the linear functions $X_{ij} - \bar{X}_{\cdot j}$ and $\bar{X}_{\cdot j} - \bar{X}_{\cdot \cdot}$ are uncorrelated.

Hint: Recall the definition of $\bar{X}_{\cdot j}$ and $\bar{X}_{\cdot \cdot}$ and, without loss of generality, we can let $E(X_{ij}) = 0$ for all i, j .

9.2.3. The following are observations associated with independent random samples from three normal distributions having equal variances and respective means μ_1, μ_2, μ_3 .

	I	II	III
	0.5	2.1	3.0
	1.3	3.3	5.1
	-1.0	0.0	1.9
	1.8	2.3	2.4
	2.5	4.2	
	4.1		

Using R or another statistical package, compute the F -statistic that is used to test $H_0 : \mu_1 = \mu_2 = \mu_3$.

9.2.4. Let X_1, X_2, \dots, X_n be a random sample from a normal distribution $N(\mu, \sigma^2)$. Show that

$$\sum_{i=1}^n (X_i - \bar{X})^2 = \sum_{i=2}^n (X_i - \bar{X}')^2 + \frac{n-1}{n} (X_1 - \bar{X}')^2,$$

where $\bar{X} = \sum_{i=1}^n X_i/n$ and $\bar{X}' = \sum_{i=2}^n X_i/(n-1)$.

Hint: Replace $X_i - \bar{X}$ by $(X_i - \bar{X}') - (X_1 - \bar{X}')/n$. Show that $\sum_{i=2}^n (X_i - \bar{X}')^2/\sigma^2$ has a chi-square distribution with $n - 2$ degrees of freedom. Prove that the two terms in the right-hand member are independent. What then is the distribution of

$$\frac{[(n-1)/n](X_1 - \bar{X}')^2}{\sigma^2}?$$

9.2.5. Using the notation of this section, assume that the means satisfy the condition that $\mu = \mu_1 + (b - 1)d = \mu_2 - d = \mu_3 - d = \dots = \mu_b - d$. That is, the last $b - 1$ means are equal but differ from the first mean μ_1 , provided that $d \neq 0$. Let independent random samples of size a be taken from the b normal distributions with common unknown variance σ^2 .

- (a) Show that the maximum likelihood estimators of μ and d are $\hat{\mu} = \bar{X}_{..}$ and

$$\hat{d} = \frac{\sum_{j=2}^b \bar{X}_{.j} / (b - 1) - \bar{X}_{..}}{b}.$$

- (b) Using Exercise 9.2.4, find Q_6 and $Q_7 = c\hat{d}^2$ so that, when $d = 0$, Q_7/σ^2 is $\chi^2(1)$ and

$$\sum_{i=1}^a \sum_{j=1}^b (X_{ij} - \bar{X}_{..})^2 = Q_3 + Q_6 + Q_7.$$

- (c) Argue that the three terms in the right-hand member of part (b), once divided by σ^2 , are independent random variables with chi-square distributions, provided that $d = 0$.
- (d) The ratio $Q_7/(Q_3 + Q_6)$ times what constant has an F -distribution, provided that $d = 0$? Note that this F is really the square of the two-sample T used to test the equality of the mean of the first distribution and the common mean of the other distributions, in which the last $b - 1$ samples are combined into one.

9.2.6. On page 123 of their text, Kroke and McKean (2014) present the results of an experiment investigating 4 drugs (treatments) for their effect on lowering LDL (low density lipids) cholesterol. For the experimental design, 39 quail were randomly assigned to one of the 4 drugs. The drug was mixed in their food, but, other than this, the quail were all treated in the same way. After a specified period of time, the LDL level of each quail was determined. The first drug was a placebo, so the interest is to see if any other of the drugs resulted in lower LDL than the placebo. The data are in the file `quailldl.rda`. The first column of this matrix contains the drug indicator (1 through 4) for the quail while the second column contains the ldl level of that quail.

- (a) Obtain comparison boxplots of LDL levels. Which drugs seem to result in lower LDL levels? Identify, by observation number, the outliers in the data.
- (b) Compute the F -test that all mean levels of LDL are the same for all 4 drugs. Report the F -test statistic and p -value. Conclude in terms of the problem using the nominal significance level of 0.05. Use the R code in Example 9.2.1.
- (c) Does your conclusion in Part (b) agree with the boxplots of Part (a)?

- (d) Note that one assumption for the F -test is that the random errors e_{ij} in Model (9.2.1) are normally distributed. An estimate of e_{ij} is $x_{ij} - \bar{x}_{\cdot j}$. These are called **residuals**, i.e., what is left after the full model fit. Compute these residuals and then obtain a histogram, a boxplot, and a normal $q-q$ plot of them. Comment on the normality assumption. Use the code:

```
resd <- lm(quailmat[,2]~factor(quailmat[,1]))$resid
par(mfrow=c(2,2)); hist(resd); boxplot(resd); qqnorm(resd)
```

9.2.7. Let μ_1, μ_2, μ_3 be, respectively, the means of three normal distributions with a common but unknown variance σ^2 . In order to test, at the $\alpha = 5\%$ significance level, the hypothesis $H_0 : \mu_1 = \mu_2 = \mu_3$ against all possible alternative hypotheses, we take an independent random sample of size 4 from each of these distributions. Determine whether we accept or reject H_0 if the observed values from these three distributions are, respectively,

$$\begin{array}{cccc} X_1 : & 5 & 9 & 6 & 8 \\ X_2 : & 11 & 13 & 10 & 12 \\ X_3 : & 10 & 6 & 9 & 9 \end{array}$$

9.2.8. The driver of a diesel-powered automobile decided to test the quality of three types of diesel fuel sold in the area based on mpg. Test the null hypothesis that the three means are equal using the following data. Make the usual assumptions and take $\alpha = 0.05$.

$$\begin{array}{ccccc} \text{Brand A:} & 38.7 & 39.2 & 40.1 & 38.9 \\ \text{Brand B:} & 41.9 & 42.3 & 41.3 & \\ \text{Brand C:} & 40.8 & 41.2 & 39.5 & 38.9 & 40.3 \end{array}$$

9.3 Noncentral χ^2 and F -Distributions

Let X_1, X_2, \dots, X_n denote independent random variables that are $N(\mu_i, \sigma^2)$, $i = 1, 2, \dots, n$, and consider the quadratic form $Y = \sum_1^n X_i^2 / \sigma^2$. If each μ_i is zero, we know that Y is $\chi^2(n)$. We shall now investigate the distribution of Y when each μ_i is not zero. The mgf of Y is given by

$$\begin{aligned} M(t) &= E \left[\exp \left(t \sum_{i=1}^n \frac{X_i^2}{\sigma^2} \right) \right] \\ &= \prod_{i=1}^n E \left[\exp \left(t \frac{X_i^2}{\sigma^2} \right) \right]. \end{aligned}$$

Consider

$$E \left[\exp \left(\frac{tX_i^2}{\sigma^2} \right) \right] = \int_{-\infty}^{\infty} \frac{1}{\sigma \sqrt{2\pi}} \exp \left[\frac{tx_i^2}{\sigma^2} - \frac{(x_i - \mu_i)^2}{2\sigma^2} \right] dx_i.$$

The integral exists if $t < \frac{1}{2}$. To evaluate the integral, note that

$$\begin{aligned} \frac{tx_i^2}{\sigma^2} - \frac{(x_i - \mu_i)^2}{2\sigma^2} &= -\frac{x_i^2(1-2t)}{2\sigma^2} + \frac{2\mu_i x_i}{2\sigma^2} - \frac{\mu_i^2}{2\sigma^2} \\ &= \frac{t\mu_i^2}{\sigma^2(1-2t)} - \frac{1-2t}{2\sigma^2} \left(x_i - \frac{\mu_i}{1-2t} \right)^2. \end{aligned}$$

Accordingly, with $t < \frac{1}{2}$, we have

$$E \left[\exp \left(\frac{tX_i^2}{\sigma^2} \right) \right] = \exp \left[\frac{t\mu_i^2}{\sigma^2(1-2t)} \right] \int_{-\infty}^{\infty} \frac{1}{\sigma\sqrt{2\pi}} \exp \left[-\frac{1-2t}{2\sigma^2} \left(x_i - \frac{\mu_i}{1-2t} \right)^2 \right] dx_i.$$

If we multiply the integrand by $\sqrt{1-2t}$, $t < \frac{1}{2}$, we have the integral of a normal pdf with mean $\mu_i/(1-2t)$ and variance $\sigma^2/(1-2t)$. Thus

$$E \left[\exp \left(\frac{tX_i^2}{\sigma^2} \right) \right] = \frac{1}{\sqrt{1-2t}} \exp \left[\frac{t\mu_i^2}{\sigma^2(1-2t)} \right],$$

and the mgf of $Y = \sum_1^n X_i^2/\sigma^2$ is given by

$$M(t) = \frac{1}{(1-2t)^{n/2}} \exp \left[\frac{t \sum_1^n \mu_i^2}{\sigma^2(1-2t)} \right], \quad t < \frac{1}{2}. \quad (9.3.1)$$

A random variable that has the mgf

$$M(t) = \frac{1}{(1-2t)^{r/2}} e^{t\theta/(1-2t)}, \quad (9.3.2)$$

where $t < \frac{1}{2}$, $0 < \theta$, and r is a positive integer, is said to have a **noncentral chi-square distribution** with r degrees of freedom and noncentrality parameter θ . If one sets the noncentrality parameter $\theta = 0$, one has $M(t) = (1-2t)^{-r/2}$, which is the mgf of a random variable that is $\chi^2(r)$. Such a random variable can appropriately be called a **central chi-square variable**. We shall use the symbol $\chi^2(r, \theta)$ to denote a noncentral chi-square distribution that has the parameters r and θ ; and we shall say that a random variable is $\chi^2(r, \theta)$ when that random variable has this kind of distribution. The symbol $\chi^2(r, 0)$ is equivalent to $\chi^2(r)$. Thus our random variable $Y = \sum_1^n X_i^2/\sigma^2$ of this section is $\chi^2(n, \sum_1^n \mu_i^2/\sigma^2)$. The mean of Y is given by

$$E(Y) = \frac{1}{\sigma^2} \sum_{i=1}^n E(X_i^2) = \frac{1}{\sigma^2} \sum_{i=1}^n (\sigma^2 + \mu_i^2) = n + \theta, \quad (9.3.3)$$

i.e., the mean of the central χ^2 plus the noncentrality parameter. If each μ_i is equal to zero, then Y is $\chi^2(n, 0)$ or, more simply, Y is $\chi^2(n)$ with mean n .

The noncentral χ^2 -variables, in which we have interest, are certain quadratic forms in normally distributed variables divided by a variance σ^2 . In our example it is worth noting that the noncentrality parameter of $\sum_1^n X_i^2/\sigma^2$, which is

$\sum_i^n \mu_i^2 / \sigma^2$, may be computed by replacing each X_i in the quadratic form by its mean μ_i , $i = 1, 2, \dots, n$. This is no fortuitous circumstance; any quadratic form $Q = Q(X_1, \dots, X_n)$ in normally distributed variables, which is such that Q/σ^2 is $\chi^2(r, \theta)$, has $\theta = Q(\mu_1, \mu_2, \dots, \mu_n)/\sigma^2$; and if Q/σ^2 is a chi-square variable (central or noncentral) for certain real values of $\mu_1, \mu_2, \dots, \mu_n$, it is chi-square (central or noncentral) for all real values of these means.

We next discuss the noncentral F -distribution. If U and V are independent and are, respectively, $\chi^2(r_1)$ and $\chi^2(r_2)$, the random variable F has been defined by $F = r_2 U / r_1 V$. Now suppose, in particular, that U is $\chi^2(r_1, \theta)$, V is $\chi^2(r_2)$, and U and V are independent. The distribution of the random variable $r_2 U / r_1 V$ is called a **noncentral F -distribution** with r_1 and r_2 degrees of freedom with noncentrality parameter θ . Note that the noncentrality parameter of F is precisely the noncentrality parameter of the random variable U , which is $\chi^2(r_1, \theta)$. To obtain the expectation of F , use the $E(U)$ in expression (9.3.3) and the derivation of the expected value of a central F given in expression (3.6.8). These together immediately imply that

$$E(F) = \frac{r_2}{r_2 - 2} \left[\frac{r_1 + \theta}{r_1} \right], \quad (9.3.4)$$

provided, of course, that $r_2 > 2$. If $\theta > 0$ then the quantity in brackets exceeds one and, hence, the mean of the noncentral F exceeds the mean of the corresponding central F .

We next discuss the noncentral F distribution for the one-way ANOVA of the last section.

Example 9.3.1 (Noncentrality Parameter for One-way ANOVA). Consider the one-way model with b levels, expression (9.2.1), with the hypotheses $H_0 : \mu_1 = \dots = \mu_b$ versus $H_1 : \mu_j \neq \mu_{j'}$ for some $j \neq j'$. From expression (9.2.11), the F test statistic is $F = [Q_4/(b-1)]/[Q_3/(n-b)]$. In the denominator, the random variable Q_3/σ^2 is $\chi^2(n-b)$ under the full model and, hence, in particular, under H_1 . It follows from Remark 9.8.3 of Section 9.8, though, that the distribution of Q_4/σ^2 is noncentral $\chi^2(b-1, \theta)$ under the full model. Recall that

$$Q_4/\sigma^2 = \frac{1}{\sigma^2} \sum_{j=1}^b n_j (\bar{X}_{\cdot j} - \bar{X}_{\cdot \cdot})^2.$$

Under the full model, $E(\bar{X}_{\cdot j}) = \mu_j$ and $E(\bar{X}_{\cdot \cdot}) = \sum_{j=1}^b (n_j/n) \mu_j$. Calling this last expectation $\bar{\mu}$, we have from the above discussion that

$$\theta = \frac{1}{\sigma^2} \sum_{j=1}^b n_j (\mu_j - \bar{\mu})^2. \quad (9.3.5)$$

If H_0 is true then $\mu_j \equiv \mu$, for some μ , and, hence, $\bar{\mu} = \mu$. Thus, under H_0 , $\theta = 0$. Under H_1 , there are distinct j and j' such that $\mu_j \neq \mu_{j'}$. In particular, then both μ_j and $\mu_{j'}$ cannot equal $\bar{\mu}$, so $\theta > 0$. Therefore, under H_1 the expectation of F exceeds the null expectation. ■

There are R commands that compute the cdf of noncentral χ^2 and F random variables. For example, suppose we want to compute $P(Y \leq y)$, where Y has a χ^2 -distribution with d degrees of freedom and noncentrality parameter b . This probability is returned with the command `pchisq(y, d, b)`. The corresponding value of the pdf at y is computed by the command `dchisq(y, d, b)`. As another example, suppose we want $P(W \geq w)$, where W has an F -distribution with n_1 and n_2 degrees of freedom and noncentrality parameter `theta`. This is computed by the command `1-pf(w, n1, n2, theta)`, while the command `df(w, n1, n2, theta)` computes the value of the density of W at w . Tables of the noncentral chi-square and noncentral F -distributions are available in the literature also.

EXERCISES

9.3.1. Let Y_i , $i = 1, 2, \dots, n$, denote independent random variables that are, respectively, $\chi^2(r_i, \theta_i)$, $i = 1, 2, \dots, n$. Prove that $Z = \sum_1^n Y_i$ is $\chi^2(\sum_1^n r_i, \sum_1^n \theta_i)$.

9.3.2. Compute the variance of a random variable that is $\chi^2(r, \theta)$.

9.3.3. Three different medical procedures (A, B, and C) for a certain disease are under investigation. For the study, $3m$ patients having this disease are to be selected and m are to be assigned to each procedure. This common sample size m must be determined. Let μ_1, μ_2 , and μ_3 , be the means of the response of interest under treatments A, B, and C, respectively. The hypotheses are: $H_0 : \mu_1 = \mu_2 = \mu_3$ versus $H_1 : \mu_j \neq \mu_{j'}$ for some $j \neq j'$. To determine m , from a pilot study the experimenters use a guess of 30 of σ^2 and they select the significance level of 0.05. They are interested in detecting the pattern of means: $\mu_2 = \mu_1 + 5$ and $\mu_3 = \mu_1 + 10$.

- (a) Determine the noncentrality parameter under the above pattern of means.
- (b) Use the R function `pf` to determine the powers of the F -test to detect the above pattern of means for $m = 5$ and $m = 10$.
- (c) Determine the smallest value of m so that the power of detection is at least 0.80.
- (d) Answer (a)–(c) if $\sigma^2 = 40$.

9.3.4. Show that the square of a noncentral T random variable is a noncentral F random variable.

9.3.5. Let X_1 and X_2 be two independent random variables. Let X_1 and $Y = X_1 + X_2$ be $\chi^2(r_1, \theta_1)$ and $\chi^2(r, \theta)$, respectively. Here $r_1 < r$ and $\theta_1 \leq \theta$. Show that X_2 is $\chi^2(r - r_1, \theta - \theta_1)$.

9.4 Multiple Comparisons

For this section, consider the one-way ANONA model with b treatments as described in expression (9.2.1) of Section 9.2. In that section, we developed the F -test

of the hypotheses of equal means, (9.2.2). In practice, besides this test, statisticians usually want to make pairwise comparisons of the form $\mu_j - \mu_{j'}$. This is often called the **Second Stage Analysis**, while the F -test is consider the **First Stage Analysis**. The analysis for such comparisons usually consists of confidence intervals for the differences $\mu_j - \mu_{j'}$ and μ_j is **declared different** from $\mu_{j'}$ if 0 is not in the confidence interval. The random samples for treatments j and j' are: $X_{1j}, \dots, X_{n_{jj}}$ from the $N(\mu_j, \sigma^2)$ distribution and $X_{1j'}, \dots, X_{n_{j'}j'}$ from the $N(\mu_{j'}, \sigma^2)$ distribution, which are independent random samples. Based on these samples the estimator of $\mu_j - \mu_{j'}$ is $\bar{X}_{\cdot j} - \bar{X}_{\cdot j'}$. Further in the one-way analysis, an estimator of σ^2 is the full model estimator $\hat{\sigma}_\Omega^2$ defined in expression (9.2.7). As discussed in Section 9.2, $(n - b)\hat{\sigma}_\Omega^2/\sigma^2$ has a $\chi^2(n - b)$ distribution which is independent of all the sample means $\bar{X}_{\cdot j}$. Hence, for a specified α it follows as in (4.2.13) of Chapter 4 that

$$\bar{X}_{\cdot j} - \bar{X}_{\cdot j'} \pm t_{\alpha/2, n-b} \hat{\sigma}_\Omega \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}} \quad (9.4.1)$$

is a $(1 - \alpha)100\%$ confidence interval for $\mu_j - \mu_{j'}$.

We often want to make many pairwise comparisons, though. For example, the first treatment might be a placebo or represent the standard treatment. In this case, there are $b - 1$ pairwise comparisons of interest. On the other hand, we may want to make all $\binom{b}{2}$ pairwise comparisons. In making so many comparisons, while each confidence interval, (9.4.1), has confidence $(1 - \alpha)$, it would seem that the overall confidence diminishes. As we next show, this **slippage** of overall confidence is true. These problems are often called **Multiple Comparison Problems (MCP)**. In this section, we present several MCP procedures.

Bonferroni Multiple Comparison Procedure

It is easy to motivate the **Bonferroni Procedure** while, at the same time, showing the slippage of confidence. This procedure is quite general and can be used in many settings not just the one-way design. So suppose we have k parameters θ_i with $(1 - \alpha)100\%$ confidence intervals I_i , $i = 1, \dots, k$, where $0 < \alpha < 1$ is given. Then the overall confidence is $P(\theta_1 \in I_1, \dots, \theta_k \in I_k)$. Using the method of complements, DeMorgan's Laws, and Boole's inequality, expression (1.3.7) of Chapter 1, we have

$$\begin{aligned} P(\theta_1 \in I_1, \dots, \theta_k \in I_k) &= 1 - P(\cup_{i=1}^k \theta_i \notin I_i) \\ &\geq 1 - \sum_{i=1}^k P(\theta_i \notin I_i) = 1 - k\alpha. \end{aligned} \quad (9.4.2)$$

The quantity $1 - k\alpha$ is the lower bound on the slippage of confidence. For example, if $k = 20$ and $\alpha = 0.05$ then the overall confidence may be 0. The Bonferroni procedure follows from expression (9.4.2). Simply change the confidence level of each confidence interval to $[1 - (\alpha/k)]$. Then the overall confidence is at least $1 - \alpha$.

For our one-way analysis, suppose we have k differences of interest. Then the

Bonferroni confidence interval for $\mu_j - \mu_{j'}$ is

$$\bar{X}_{\cdot j} - \bar{X}_{\cdot j'} \pm t_{\alpha/(2k), n-b} \hat{\sigma}_\Omega \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}} \quad (9.4.3)$$

While the overall confidence of the Bonferroni procedure is at least $(1 - \alpha)$, for a large number of comparisons, the lengths of its intervals are wide; i.e., a loss in precision. We offer two other procedures that, generally, lessen this effect.

The R function `mcpbon.R2` computes the Bonferroni procedure for all pairwise comparisons for a one-way design. The call is `mcpbon(y, ind, alpha=0.05)` where `y` is the vector of the combined samples and `ind` is the corresponding treatment vector. See Example 9.4.1 below.

Tukey's Multiple Comparison Procedure

To state **Tukey's procedure**, we first need to define the Studentized range distribution.

Definition 9.4.1. Let Y_1, \dots, Y_k be iid $N(\mu, \sigma^2)$. Denote the range of these variables by $R = \max\{Y_i\} - \min\{Y_i\}$. Suppose mS^2/σ^2 has a $\chi^2(m)$ distribution which is independent of Y_1, \dots, Y_k . Then we say that $Q = R/S$ has a **Studentized range distribution** with parameters k and m . ■

The distribution of Q cannot be obtained in close form but packages such as R have functions that compute the cdf and quantiles. In R, the call `ptukey(x, k, m)` computes the cdf of Q at x , while the call `qtukey(p, k, m)` returns the p th quantile.

Consider the one-way design. First, assume that all the sample sizes are the same; i.e., for some positive integer a , $n_j = a$, for all $j = 1, \dots, b$. Let $R = \text{Range}\{\bar{X}_{\cdot 1} - \mu_1, \dots, \bar{X}_{\cdot b} - \mu_b\}$. Then since $\bar{X}_{\cdot 1} - \mu_1, \dots, \bar{X}_{\cdot b} - \mu_b$ are iid $N(0, \sigma^2/a)$, the random variable $Q = R/(\hat{\sigma}_\Omega/\sqrt{a})$ has a Studentized range distribution with parameters b and $n - b$. Let $q_c = q_{1-\alpha, b, n-b}$.

$$\begin{aligned} 1 - \alpha &= P(Q \leq q_c) = P(\max\{\bar{X}_{\cdot j} - \mu_j\} - \min\{\bar{X}_{\cdot j} - \mu_j\} \leq q_c \hat{\sigma}_\Omega / \sqrt{a}) \\ &= P(|(\mu_j - \mu_{j'}) - (\bar{X}_{\cdot j} - \bar{X}_{\cdot j'})| \leq q_c \hat{\sigma}_\Omega / \sqrt{a}, \text{ for all } j, j') \end{aligned}$$

If we expand the inequality in the last statement, we obtain the $(1 - \alpha)100\%$ simultaneous confidence intervals for all pairwise differences given by

$$\bar{X}_{\cdot j} - \bar{X}_{\cdot j'} \pm q_{1-\alpha, b, n-b} \frac{\hat{\sigma}_\Omega}{\sqrt{a}}, \quad \text{for all } j, j' \text{ in } 1, \dots, b. \quad (9.4.4)$$

The statistician John Tukey developed these simultaneous confidence intervals for the balanced case. For the unbalanced case, first write the error term in (9.4.4) as

$$\frac{q_{1-\alpha, b, n-b}}{\sqrt{2}} \hat{\sigma}_\Omega \sqrt{\frac{1}{a} + \frac{1}{a}}$$

²Downloadable at the site listed in the Preface.

For the unbalanced case, this suggests the following intervals

$$\bar{X}_{\cdot j} - \bar{X}_{\cdot j'} \pm \frac{q_{1-\alpha, b, n-b}}{\sqrt{2}} \hat{\sigma}_\Omega \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}}, \quad \text{for all } j, j' \text{ in } 1, \dots, b. \quad (9.4.5)$$

This correction is due to Kramer and these intervals are often referred to as the Tukey-Kramer multiple comparison procedure; see Miller (1981) for discussion. These intervals do not have exact confidence $(1 - \alpha)$ but studies have indicated that if the unbalance is not severe the confidence is close to $(1 - \alpha)$; see Dunnett (1980). Corresponding R code is shown in Example 9.4.1.

Fisher's PLSD Multiple Comparison Procedure

The final procedure we discuss is **Fisher's Protected Least Significance Difference (PLSD)**. The setting is the general (unbalanced) one-way design (9.2.1). This procedure is a two-stage procedure. It can be used for an arbitrary number of comparisons but we state it for all comparisons. For a specified level of significance α , Stage 1 consists of the F -test of the hypotheses of equal means, (9.2.2). If the test rejects at level α then Stage 2 consists of the usual pairwise $(1 - \alpha)100\%$ confidence intervals, i.e.,

$$\bar{X}_{\cdot j} - \bar{X}_{\cdot j'} \pm t_{\alpha/2, n-b} \hat{\sigma}_\Omega \sqrt{\frac{1}{n_j} + \frac{1}{n_{j'}}}, \quad \text{for all } j, j' \text{ in } 1, \dots, b. \quad (9.4.6)$$

If the test in Stage 1 fails to reject, users sometimes perform Stage 2 using the Bonferroni procedure. Fisher's procedure does not have overall coverage $1 - \alpha$, but the initial F -test offers protection. Simulation studies have shown that Fisher's procedure performs well in terms of power and level; see, for instance, Carmer and Swanson (1973) and McKean et al. (1989). The R function³ `mcpfisher.R` computes this procedure as discussed in the next example.

Example 9.4.1 (Fast Cars). Kitchens (1997) discusses an experiment concerning the speed of cars. Five cars are considered: Acura (1), Ferrari (2), Lotus (3), Porsche (4), and Viper (5). For each car, 6 runs were made, 3 in each direction. For each run, the speed recorded is the maximum speed on the run achieved without exceeding the engine's redline. The data are in the file `fastcars.rda`. Figure 9.4.1 displays the comparison boxplots of the speeds versus the cars, which shows clearly that there are differences in speed due to the car. Ferrari and Porsche seem to be the fastest but are the differences significant? We assume the one-way design (9.2.1) and use R to do the computations. Key commands and corresponding results are given next. The overall F -test of the hypotheses of equal means, (9.2.2), is quite significant: $F = 25.15$ with the p -value 0.0000. We selected the Tukey MCP at level 0.05. The command below returns all $\binom{5}{2} = 10$ pairwise comparisons, but in our summary we only list two.

```

For discussion, we cite only two of Tukey's confidence intervals. As the second interval in the above printout shows, the mean speeds of both the Ferrari and Porsche are significantly faster than the mean speeds of the other cars. The difference between the Ferrari's and Porsche's mean speeds, though, is insignificant. Below the two Tukey confidence intervals, we display the results based on the Bonferroni and Fisher procedures. Note that all three procedures result in the same conclusions for these comparisons. The Bonferroni intervals are slightly larger than those of the Tukey procedure. The Fisher procedure gives the shortest intervals as expected. ■

In practice, the Tukey-Kramer procedure is often used, but there are many other multiple comparison procedures. A classical monograph on MCPs is Miller (1981) while Hus (1996) offers a more recent discussion.

EXERCISES

9.4.1. For the study discussed in Exercise 9.2.8, obtain the results of Bonferroni multiple comparison procedure using $\alpha = 0.10$. Based on this procedure, which brand of fuel if any is significantly best?

9.4.2. For the study discussed in Exercise 9.2.6, compute the Tukey-Kramer procedure. Are there any significant differences?

9.4.3. Suppose X and Y are discrete random variables that have the common range $\{1, 2, \dots, k\}$. Let p_{1j} and p_{2j} be the respective probabilities $P(X = j)$ and

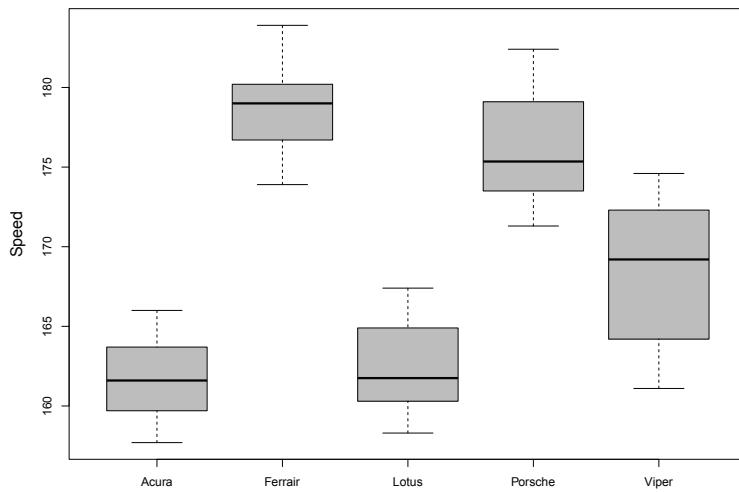

Figure 9.4.1: Boxplot of car speeds cited in Example 9.4.1.

$P(Y = j)$. Let X_1, \dots, X_{n_1} and Y_1, \dots, Y_{n_2} be respective independent random samples on X and Y . The samples are recorded in a $2 \times k$ contingency table of counts O_{ij} , where $O_{1j} = \#\{X_i = j\}$ and $O_{2j} = \#\{Y_i = j\}$. In Example 4.7.3, based on this table, we discussed a test that the distributions of X and Y are the same. Here we want to consider all the differences $p_{1j} - p_{2j}$ for $j = 1, \dots, k$. Let $\hat{p}_{ij} = O_{ij}/n_i$.

- (a) Determine the Bonferroni method for performing all these comparisons.
- (b) Determine the Fisher method for performing all these comparisons.

9.4.4. Suppose the samples in Exercise 9.4.3 resulted in the contingency table:

	1	2	3	4	5	6	7	8	9	10
x	20	31	56	18	45	55	47	78	56	81
y	36	41	65	15	38	78	18	72	59	85

To compute (in R) the confidence intervals below, use the command `prop.test` as in Example 4.2.5.

- (a) Based on the Bonferroni procedure for all 10 comparisons, compute the confidence interval for $p_{16} - p_{26}$.
- (b) Based on the Fisher procedure for all 10 comparisons, compute the confidence interval for $p_{16} - p_{26}$.

9.4.5. Write an R function that computes the Fisher procedure of Exercise 9.4.3. Validate it using the data of Exercise 9.4.4.

9.4.6. Extend the Bonferroni procedure to simultaneous testing. That is, suppose we have m hypotheses of interest: H_{0i} versus H_{1i} , $i = 1, \dots, m$. For testing H_{0i} versus H_{1i} , let $C_{i,\alpha}$ be a critical region of size α and assume H_{0i} is rejected if $\mathbf{X}_i \in C_{i,\alpha}$, for a sample \mathbf{X}_i . Determine a rule so that we can simultaneously test these m hypotheses with a Type I error rate less than or equal to α .

9.5 Two-Way ANOVA

Recall the one-way analysis of variance (ANOVA) problem considered in Section 9.2 which was concerned with one factor at b levels. In this section, we are concerned with the situation where we have two factors A and B with levels a and b , respectively. This is called a **two-way** analysis of variance (ANOVA). Let X_{ij} , $i = 1, 2, \dots, a$ and $j = 1, 2, \dots, b$, denote the response for factor A at level i and factor B at level j . Denote the total sample size by $n = ab$. We shall assume that the X_{ij} s are independent normally distributed random variables with common variance σ^2 . Denote the mean of X_{ij} by μ_{ij} . The mean μ_{ij} is often referred to as the mean of the (i, j) th cell. For our first model, we consider the **additive model** where

$$\mu_{ij} = \bar{\mu} + (\bar{\mu}_{i\cdot} - \bar{\mu}) + (\bar{\mu}_{\cdot j} - \bar{\mu}); \quad (9.5.1)$$

that is, the mean in the (i, j) th cell is due to additive effects of the levels, i of factor A and j of factor B , over the average (constant) $\bar{\mu}$. Let $\alpha_i = \bar{\mu}_{i\cdot} - \bar{\mu}$, $i = 1, \dots, a$; $\beta_j = \bar{\mu}_{\cdot j} - \bar{\mu}$, $j = 1, \dots, b$; and $\mu = \bar{\mu}$. Then the model can be written more simply as

$$\mu_{ij} = \mu + \alpha_i + \beta_j, \quad (9.5.2)$$

where $\sum_{i=1}^a \alpha_i = 0$ and $\sum_{j=1}^b \beta_j = 0$. We refer to this model as being a **two-way additive ANOVA model**.

For example, take $a = 2$, $b = 3$, $\mu = 5$, $\alpha_1 = 1$, $\alpha_2 = -1$, $\beta_1 = 1$, $\beta_2 = 0$, and $\beta_3 = -1$. Then the cell means are

		Factor B		
		1	2	3
Factor A	1	$\mu_{11} = 7$	$\mu_{12} = 6$	$\mu_{13} = 5$
	2	$\mu_{21} = 5$	$\mu_{22} = 4$	$\mu_{23} = 3$

Note that for each i , the plots of μ_{ij} versus j are parallel. This is true for additive models in general; see Exercise 9.5.9. We call these plots **mean profile plots**.

Had we taken $\beta_1 = \beta_2 = \beta_3 = 0$, then the cell means would be

		Factor B		
		1	2	3
Factor A	1	$\mu_{11} = 6$	$\mu_{12} = 6$	$\mu_{13} = 6$
	2	$\mu_{21} = 4$	$\mu_{22} = 4$	$\mu_{23} = 4$

The hypotheses of interest are

$$H_{0A} : \alpha_1 = \dots = \alpha_a = 0 \text{ versus } H_{1A} : \alpha_i \neq 0, \text{ for some } i, \quad (9.5.3)$$

and

$$H_{0B} : \beta_1 = \cdots = \beta_b = 0 \text{ versus } H_{1B} : \beta_j \neq 0, \text{ for some } j. \quad (9.5.4)$$

If H_{0A} is true, then by (9.5.2) the mean of the (i, j) th cell does not depend on the level of A . The second example above is under H_{0B} . The cell means remain the same from column to column for a specified row. We call these hypotheses **main effect** hypotheses.

Remark 9.5.1. The model just described, and others similar to it, are widely used in statistical applications. Consider a situation in which it is desirable to investigate the effects of two factors that influence an outcome. Thus the variety of a grain and the type of fertilizer used influence the yield; or the teacher and the size of the class may influence the score on a standardized test. Let X_{ij} denote the yield from the use of variety i of a grain and type j of fertilizer. A test of the hypothesis that $\beta_1 = \beta_2 = \cdots = \beta_b = 0$ would then be a test of the hypothesis that the mean yield of each variety of grain is the same regardless of the type of fertilizer used. ■

Call the model described around expression (9.5.2) the full model. We want to determine the mles. If we write out the likelihood function, the summation in the exponent of e is

$$SS = \sum_{i=1}^a \sum_{j=1}^b (x_{ij} - \bar{\mu} - \alpha_i - \beta_j)^2.$$

The mles of α_i , β_j , and $\bar{\mu}$ minimize SS . By adding in and subtracting out, we obtain:

$$SS = \sum_{i=1}^a \sum_{j=1}^b \{[\bar{x}_{..} - \bar{\mu}] - [\alpha_i - (\bar{x}_{i\cdot} - \bar{x}_{..})] - [\beta_j - (\bar{x}_{\cdot j} - \bar{x}_{..})] + [x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}]\}^2. \quad (9.5.5)$$

From expression (9.5.2), we have $\sum_i \alpha_i = \sum_j \beta_j = 0$. Further,

$$\sum_{i=1}^a (\bar{x}_{i\cdot} - \bar{x}_{..}) = \sum_{j=1}^b (\bar{x}_{\cdot j} - \bar{x}_{..}) = 0$$

and

$$\sum_{i=1}^a (x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}) = \sum_{j=1}^b (x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}) = 0.$$

Therefore, in the expansion of the sum of squares, (9.5.5), all cross product terms are 0. Hence, we have the identity

$$\begin{aligned} SS &= ab[\bar{x}_{..} - \bar{\mu}]^2 + b \sum_{i=1}^a [\alpha_i - (\bar{x}_{i\cdot} - \bar{x}_{..})]^2 + a \sum_{j=1}^b [\beta_j - (\bar{x}_{\cdot j} - \bar{x}_{..})]^2 \\ &\quad + \sum_{i=1}^a \sum_{j=1}^b [x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}]^2. \end{aligned} \quad (9.5.6)$$

Since these are sums of squares, the minimizing values, (mles), must be

$$\hat{\mu} = \bar{X}_{..}, \hat{\alpha}_i = \bar{X}_{i\cdot} - \bar{X}_{..}, \text{ and } \hat{\beta}_j = \bar{X}_{\cdot j} - \bar{X}_{..}. \quad (9.5.7)$$

Note that we have used random variable notation. So these are the maximum likelihood estimators. It then follows that the maximum likelihood estimator of σ^2 is

$$\hat{\sigma}_\Omega^2 = \frac{\sum_{i=1}^a \sum_{j=1}^b [X_{ij} - \bar{X}_{i\cdot} - \bar{X}_{\cdot j} + \bar{X}_{..}]^2}{ab} = \text{dfn } \frac{Q'_3}{ab}, \quad (9.5.8)$$

where we have defined the numerator of $\hat{\sigma}_\Omega^2$ as the quadratic form Q'_3 . It follows from an advanced course in linear models that $ab\hat{\sigma}_\Omega^2/\sigma^2$ has a $\chi^2((a-1)(b-1))$ distribution.

Next we construct the likelihood ratio test for H_{0B} . Under the reduced model (full model constrained by H_{0B}), $\beta_j = 0$ for all $j = 1, \dots, b$. To obtain the mles for the reduced model, the identity (9.5.6) becomes

$$\begin{aligned} SS &= ab[\bar{x}_{..} - \bar{\mu}]^2 + b \sum_{i=1}^a [\alpha_i - (\bar{x}_{i\cdot} - \bar{x}_{..})]^2 \\ &\quad + a \sum_{j=1}^b [\bar{x}_{\cdot j} - \bar{x}_{..}]^2 + \sum_{i=1}^a \sum_{j=1}^b [x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}]^2. \end{aligned} \quad (9.5.9)$$

Thus the mles for α_i and $\bar{\mu}$ remain the same as in the full model and the reduced model maximum likelihood estimator of σ^2 is

$$\hat{\sigma}_\omega^2 = \frac{\left\{ a \sum_{j=1}^b [\bar{x}_{\cdot j} - \bar{x}_{..}]^2 + \sum_{i=1}^a \sum_{j=1}^b [x_{ij} - \bar{x}_{i\cdot} - \bar{x}_{\cdot j} + \bar{x}_{..}]^2 \right\}}{ab}. \quad (9.5.10)$$

Denote the numerator of $\hat{\sigma}_\omega^2$ by Q' . Note that it is the **residual variation** left after fitting the reduced model.

Let Λ denote the likelihood ratio test statistic for H_{0B} . Our derivation is similar to the derivation for the likelihood ratio test statistic for one-way ANOVA of Section 9.2. Hence, similar to equation (9.2.9), our likelihood ratio test statistic simplifies to

$$\Lambda^{ab/2} = \frac{\hat{\sigma}_\Omega^2}{\hat{\sigma}_\omega^2} = \frac{Q'_3}{Q'}.$$

Then, similar to the one-way derivation, the likelihood ratio test rejects H_{0B} for large values of Q'_4/Q'_3 , where in this case,

$$Q'_4 = a \sum_{j=1}^b [\bar{x}_{\cdot j} - \bar{x}_{..}]^2. \quad (9.5.11)$$

Note that $Q'_4 = Q' - Q'_3$; i.e., it is the incremental increase in residual variation if we use the reduced model instead of the full model.

To obtain the null distribution of Q'_4 , notice that it is the numerator of the sample variance of the random variables $\sqrt{a}\bar{X}_{\cdot 1}, \dots, \sqrt{a}\bar{X}_{\cdot b}$. These random variables are

independent with the common $N(\sqrt{a}\bar{\mu}, \sigma^2)$ distribution; see Exercise 9.5.2. Hence, by Theorem 3.6.1, Q'_4/σ^2 has $\chi^2(b-1)$ distribution. In a more advanced course, it can be further shown that Q'_4 and Q'_3 are independent. Hence, the statistic

$$F_B = \frac{a \sum_{j=1}^b [\bar{X}_{\cdot j} - \bar{X}_{..}]^2 / (b-1)}{\sum_{i=1}^a \sum_{j=1}^b [X_{ij} - \bar{X}_{i\cdot} - \bar{X}_{\cdot j} + \bar{X}_{..}]^2 / (a-1)(b-1)} \quad (9.5.12)$$

has an $F(b-1, (a-1)(b-1))$ under H_{0B} . Thus, a level α test is to reject H_{0B} in favor of H_{1B} if

$$F_B \geq F(\alpha, b-1, (a-1)(b-1)). \quad (9.5.13)$$

If we are to compute the power function of the test, we need the distribution of F_B when H_{0B} is not true. As we have stated above, Q'_3/σ^2 , (9.5.8), has a central χ^2 -distribution with $(a-1)(b-1)$ degrees of freedom under the full model, and, hence, under H_{1B} . Further, it can be shown that Q'_4 , (9.5.11), has a noncentral χ^2 -distribution with $b-1$ degrees of freedom under H_{1B} . To compute the noncentrality parameters of Q'_4/σ^2 when H_{1B} is true, we have $E(X_{ij}) = \mu + \alpha_i + \beta_j$, $E(\bar{X}_{i\cdot}) = \mu + \alpha_i$, $E(\bar{X}_{\cdot j}) = \mu + \beta_j$, and $E(\bar{X}_{..}) = \mu$. Using the general rule discussed in Section 9.4, we replace the variables in Q'_4/σ^2 with their means. Accordingly, the noncentrality parameter Q'_4/σ^2 is

$$\frac{a}{\sigma^2} \sum_{j=1}^b (\mu + \beta_j - \mu)^2 = \frac{a}{\sigma^2} \sum_{j=1}^b \beta_j^2.$$

Thus, if the hypothesis H_{0B} is not true, F has a noncentral F -distribution with $b-1$ and $(a-1)(b-1)$ degrees of freedom and noncentrality parameter $a \sum_{j=1}^b \beta_j^2 / \sigma^2$.

A similar argument can be used to construct the likelihood ratio test statistics F_A to test H_{0A} versus H_{1A} , (9.5.3). The numerator of the F test statistic is the sum of squares among rows. The test statistic is

$$F_A = \frac{b \sum_{i=1}^a [\bar{X}_{i\cdot} - \bar{X}_{..}]^2 / (a-1)}{\sum_{i=1}^a \sum_{j=1}^b [X_{ij} - \bar{X}_{i\cdot} - \bar{X}_{\cdot j} + \bar{X}_{..}]^2 / (a-1)(b-1)} \quad (9.5.14)$$

and it has an $F(a-1, (a-1)(b-1))$ distribution under H_{0A} .

9.5.1 Interaction between Factors

The analysis of variance problem that has just been discussed is usually referred to as a *two-way classification with one observation per cell*. Each combination of i and j determines a cell; thus, there is a total of ab cells in this model. Let us now investigate another two-way classification problem, but in this case we take $c > 1$ independent observations per cell.

Let X_{ijk} , $i = 1, 2, \dots, a$, $j = 1, 2, \dots, b$, and $k = 1, 2, \dots, c$, denote $n = abc$ random variables that are independent and have normal distributions with common, but unknown, variance σ^2 . Denote the mean of each X_{ijk} , $k = 1, 2, \dots, c$, by μ_{ij} .

Under the additive model, (9.5.1), the mean of each cell depended on its row and column, but often the mean is cell-specific. To allow this, consider the parameters

$$\begin{aligned}\gamma_{ij} &= \mu_{ij} - \{\mu + (\bar{\mu}_{i\cdot} - \mu) + (\bar{\mu}_{\cdot j} - \mu)\} \\ &= \mu_{ij} - \bar{\mu}_{i\cdot} - \bar{\mu}_{\cdot j} + \mu,\end{aligned}$$

for $i = 1, \dots, a, j = 1, \dots, b$. Hence γ_{ij} reflects the specific contribution to the cell mean over and above the additive model. These parameters are called **interaction parameters**. Using the second form (9.5.2), we can write the cell means as

$$\mu_{ij} = \mu + \alpha_i + \beta_j + \gamma_{ij}, \quad (9.5.15)$$

where $\sum_{i=1}^a \alpha_i = 0$, $\sum_{j=1}^b \beta_j = 0$, and $\sum_{i=1}^a \gamma_{ij} = \sum_{j=1}^b \gamma_{ij} = 0$. This model is called a **two-way** model with interaction.

For example, take $a = 2$, $b = 3$, $\mu = 5$, $\alpha_1 = 1$, $\alpha_2 = -1$, $\beta_1 = 1$, $\beta_2 = 0$, $\beta_3 = -1$, $\gamma_{11} = 1$, $\gamma_{12} = 1$, $\gamma_{13} = -2$, $\gamma_{21} = -1$, $\gamma_{22} = -1$, and $\gamma_{23} = 2$. Then the cell means are

		Factor B		
		1	2	3
Factor A	1	$\mu_{11} = 8$	$\mu_{12} = 7$	$\mu_{13} = 3$
	2	$\mu_{21} = 4$	$\mu_{22} = 3$	$\mu_{23} = 5$

If each $\gamma_{ij} = 0$, then the cell means are

		Factor B		
		1	2	3
Factor A	1	$\mu_{11} = 7$	$\mu_{12} = 6$	$\mu_{13} = 5$
	2	$\mu_{21} = 5$	$\mu_{22} = 4$	$\mu_{23} = 3$

Note that the mean profile plots for this second example are parallel, but those in the first example (where interaction is present) are not.

The derivation of the mles under the full model, (9.5.15), is quite similar to the derivation for the additive model. Letting SS denote the sums of squares in the exponent of e in the likelihood function, we obtain the following identity by adding in and subtracting out (we have omitted subscripts on the sums):

$$\begin{aligned}SS &= \sum \sum \sum (x_{ijk} - \mu - \alpha_i - \beta_j - \gamma_{ijk})^2 \\ &= \sum \sum \sum \{[x_{ijk} - \bar{x}_{ij\cdot}] - [\mu - \bar{x}_{\dots}] - [\alpha_i - (\bar{x}_{i\cdot\cdot} - \bar{x}_{\dots})] - [\beta_j - (\bar{x}_{\cdot j\cdot} - \bar{x}_{\dots})] \\ &\quad - [\gamma_{ij} - (\bar{x}_{ij\cdot} - \bar{x}_{i\cdot\cdot} - \bar{x}_{\cdot j\cdot} + \bar{x}_{\dots})]\}^2 \\ &= \sum \sum \sum [x_{ijk} - \bar{x}_{ij\cdot}]^2 + abc[\mu - \bar{x}_{\dots}]^2 + bc \sum [\alpha_i - (\bar{x}_{i\cdot\cdot} - \bar{x}_{\dots})]^2 + \\ &\quad ac \sum [\beta_j - (\bar{x}_{\cdot j\cdot} - \bar{x}_{\dots})]^2 + c \sum \sum [\gamma_{ij} - (\bar{x}_{ij\cdot} - \bar{x}_{i\cdot\cdot} - \bar{x}_{\cdot j\cdot} + \bar{x}_{\dots})]^2 \quad (9.5.16)\end{aligned}$$

where, as in the additive model, the cross product terms in the expansion are 0. Thus, the mles of μ , α_i and β_j are the same as in the additive model; the mle of γ_{ij} is $\hat{\gamma}_{ij} = \bar{X}_{ij\cdot} - \bar{X}_{i\cdot\cdot} - \bar{X}_{\cdot j\cdot} + \bar{X}_{\dots}$; and the mle of σ^2 is

$$\hat{\sigma}_\Omega^2 = \frac{\sum \sum \sum [x_{ijk} - \bar{x}_{ij\cdot}]^2}{abc}. \quad (9.5.17)$$

Let Q_3'' denote the numerator of $\hat{\sigma}^2$.

The major hypotheses of interest for the interaction model are

$$H_{0AB} : \gamma_{ij} = 0 \text{ for all } i, j \text{ versus } H_{1AB} : \gamma_{ij} \neq 0, \text{ for some } i, j. \quad (9.5.18)$$

Substituting $\gamma_{ij} = 0$ in SS , it is clear that the reduced model mle of σ^2 is

$$\hat{\sigma}_\omega^2 = \frac{\sum \sum \sum [X_{ijk} - \bar{X}_{ij.}]^2 + c \sum \sum [\bar{X}_{ij.} - \bar{X}_{i..} - \bar{X}_{.j.} + \bar{X}_{...}]^2}{abc}. \quad (9.5.19)$$

Let Q'' denote the numerator of $\hat{\sigma}_\omega^2$ and let $Q_4'' = Q'' - Q_3''$. Then it follows as in the additive model that the likelihood ratio test statistic rejects H_{0AB} for large values of Q_4''/Q_3'' . In a more advanced class, it is shown that the standardized test statistic

$$F_{AB} = \frac{Q_4''/[(a-1)(b-1)]}{Q_3''/[ab(c-1)]} \quad (9.5.20)$$

has under H_{0AB} an F -distribution with $(a-1)(b-1)$ and $ab(c-1)$ degrees of freedom.

If $H_{0AB} : \gamma_{ij} = 0$ is accepted, then one usually continues to test $\alpha_i = 0$, $i = 1, 2, \dots, a$, by using the test statistic

$$F = \frac{bc \sum_{i=1}^a (\bar{X}_{i..} - \bar{X}_{...})^2 / (a-1)}{\sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (X_{ijk} - \bar{X}_{ij.})^2 / [ab(c-1)]},$$

which has a null F -distribution with $a-1$ and $ab(c-1)$ degrees of freedom. Similarly, the test of $\beta_j = 0$, $j = 1, 2, \dots, b$, proceeds by using the test statistic

$$F = \frac{ac \sum_{j=1}^b (\bar{X}_{.j.} - \bar{X}_{...})^2 / (b-1)}{\sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (X_{ijk} - \bar{X}_{ij.})^2 / [ab(c-1)]},$$

which has a null F -distribution with $b-1$ and $ab(c-1)$ degrees of freedom.

We conclude this section with an example that serves as an illustration of two-way ANOVA along with its associated R code.

Example 9.5.1. Devore (2012), page 435, presents a study concerning the effects to the thermal conductivity of an asphalt mix due to two factors: Binder Grade at three different levels (PG58, PG64, and PG70) and Coarseness of Aggregate Content at three levels (38%, 41%, and 44%). Hence, there are $3 \times 3 = 9$ different treatments. The responses are the thermal conductivities of the mixes of asphalt at these crossed levels. Two replications were performed at each treatment. The data are:

	Coarse Aggregate Content		
Binder-Grade	38%	41%	44%
PG58	0.835	0.822	0.785
	0.845	0.826	0.795
PG64	0.855	0.832	0.790
	0.865	0.836	0.800
PG70	0.815	0.800	0.770
	0.825	0.820	0.790

The data are also in the file `conductivity.rda`. Assuming this file has been loaded into the R work area, the mean profile plot is computed by

```
interaction.plot(Binder, Aggregate, Conductivity, legend=T)
```

and it is displayed in Figure 9.5.1. Note that the mean profiles are almost parallel, a graphical indication of little interaction between the factors. The ANOVA for the study is computed by the following two commands. It yields the tabled results (which we have abbreviated). The next to last column shows the *F*-test statistics discussed in this section.

```
fit=lm(Conductivity ~ factor(Binder) + factor(Aggregate) +
       factor(Binder)*factor(Aggregate))
anova(fit)
Analysis of Variance Table
```

	Df	Sum Sq	F value	Pr(>F)
factor(Binder)	2	0.0020893	14.1171	0.001678
factor(Aggregate)	2	0.0082973	56.0631	8.308e-06
factor(Binder):factor(Aggregate)	4	0.0003253	1.0991	0.413558

As the interaction plot suggests, interaction is not significant ($p = 0.4135$). In practice, we would accept the additive (no interaction) model. The main effects are both highly significant. So both factors have an effect on conductivity. See Devore (2012) for more discussion. ■

EXERCISES

9.5.1. For the two-way interaction model, (9.5.15), show that the following decomposition of sums of squares is true:

$$\begin{aligned} \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (X_{ijk} - \bar{X}_{...})^2 &= bc \sum_{i=1}^a (\bar{X}_{i..} - \bar{X}_{...})^2 + ac \sum_{j=1}^b (\bar{X}_{.j.} - \bar{X}_{...})^2 \\ &\quad + c \sum_{i=1}^a \sum_{j=1}^b (\bar{X}_{ij.} - \bar{X}_{i..} - \bar{X}_{.j.} + \bar{X}_{...})^2 \\ &\quad + \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (X_{ijk} - \bar{X}_{ij.})^2; \end{aligned}$$

that is, the total sum of squares is decomposed into that due to *row* differences, that due to *column* differences, that due to *interaction*, and that *within cells*.

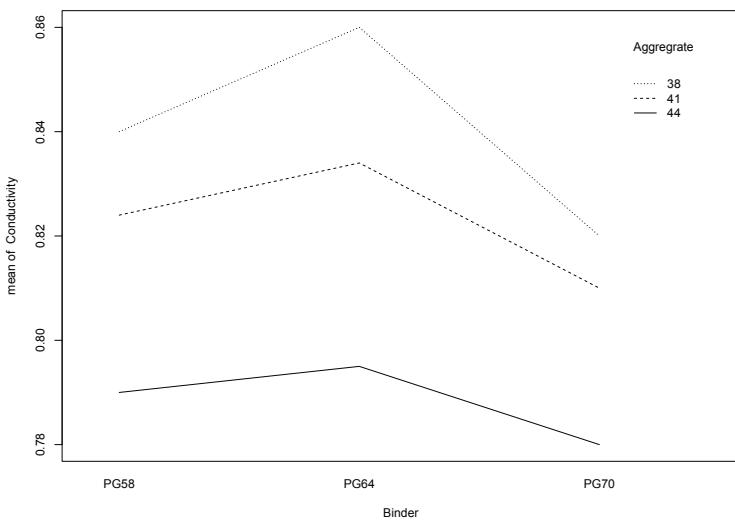

Figure 9.5.1: Mean profile plot for the study discussed in Example 9.5.1. The profiles are nearly parallel, indicating little interaction between the factors.

9.5.2. Consider the discussion above expression (9.5.14). Show that the random variables $\sqrt{a}\bar{X}_{.1}, \dots, \sqrt{a}\bar{X}_{.b}$ are independent with the common $N(\sqrt{a}\bar{\mu}, \sigma^2)$ distribution.

9.5.3. For the two-way interaction model, (9.5.15), show that the noncentrality parameter of the test statistic F_{AB} is equal to $c \sum_{j=1}^b \sum_{i=1}^a \gamma_{ij}^2 / \sigma^2$.

9.5.4. Using the background of the two-way classification with one observation per cell, determine the distribution of the maximum likelihood estimators of α_i , β_j , and μ .

9.5.5. Prove that the linear functions $X_{ij} - \bar{X}_{i\cdot} - \bar{X}_{.j} + \bar{X}_{..}$ and $\bar{X}_{.j} - \bar{X}_{..}$ are uncorrelated, under the assumptions of this section.

9.5.6. Given the following observations associated with a two-way classification with $a = 3$ and $b = 4$, use R or another statistical package to compute the F -statistic used to test the equality of the column means ($\beta_1 = \beta_2 = \beta_3 = \beta_4 = 0$) and the equality of the row means ($\alpha_1 = \alpha_2 = \alpha_3 = 0$), respectively.

Row/Column	1	2	3	4
1	3.1	4.2	2.7	4.9
2	2.7	2.9	1.8	3.0
3	4.0	4.6	3.0	3.9

9.5.7. With the background of the two-way classification with $c > 1$ observations per cell, determine the distribution of the mles of α_i , β_j , and γ_{ij} .

9.5.8. Given the following observations in a two-way classification with $a = 3$, $b = 4$, and $c = 2$, compute the F -statistics used to test that all interactions are equal to zero ($\gamma_{ij} = 0$), all column means are equal ($\beta_j = 0$), and all row means are equal ($\alpha_i = 0$), respectively. Data are in the form x_{ijk} , i, j in the data set `sec951.rda`.

Row/Column	1	2	3	4
1	3.1	4.2	2.7	4.9
	2.9	4.9	3.2	4.5
2	2.7	2.9	1.8	3.0
	2.9	2.3	2.4	3.7
3	4.0	4.6	3.0	3.9
	4.4	5.0	2.5	4.2

9.5.9. For the additive model (9.5.1), show that the mean profile plots are parallel. The sample mean profile plots are given by plotting \bar{X}_{ij} versus j , for each i . These offer a graphical diagnostic for interaction detection. Obtain these plots for the last exercise.

9.5.10. We wish to compare compressive strengths of concrete corresponding to $a = 3$ different drying methods (treatments). Concrete is mixed in batches that are just large enough to produce three cylinders. Although care is taken to achieve uniformity, we expect some variability among the $b = 5$ batches used to obtain the following compressive strengths. (There is little reason to suspect interaction, and hence only one observation is taken in each cell.) Data are also in the data set `sec95set2.rda`.

Treatment	Batch				
	B_1	B_2	B_3	B_4	B_5
A_1	52	47	44	51	42
A_2	60	55	49	52	43
A_3	56	48	45	44	38

- (a) Use the 5% significance level and test $H_A : \alpha_1 = \alpha_2 = \alpha_3 = 0$ against all alternatives.
- (b) Use the 5% significance level and test $H_B : \beta_1 = \beta_2 = \beta_3 = \beta_4 = \beta_5 = 0$ against all alternatives.

9.5.11. With $a = 3$ and $b = 4$, find μ, α_i, β_j and γ_{ij} if μ_{ij} , for $i = 1, 2, 3$ and $j = 1, 2, 3, 4$, are given by

$$\begin{matrix} 6 & 7 & 7 & 12 \\ 10 & 3 & 11 & 8 \\ 8 & 5 & 9 & 10 \end{matrix}$$

9.6 A Regression Problem

There is often interest in the relationship between two variables, for example, a student's scholastic aptitude test score in mathematics and this same student's

grade in calculus. Frequently, one of these variables, say x , is known in advance of the other and there is interest in predicting a future random variable Y . Since Y is a random variable, we cannot predict its future observed value $Y = y$ with certainty. Thus let us first concentrate on the problem of estimating the mean of Y , that is, $E(Y)$. Now $E(Y)$ is usually a function of x ; for example, in our illustration with the calculus grade, say Y , we would expect $E(Y)$ to increase with increasing mathematics aptitude score x . Sometimes $E(Y) = \mu(x)$ is assumed to be of a given form, such as a linear or quadratic or exponential function; that is, $\mu(x)$ could be assumed to be equal to $\alpha + \beta x$ or $\alpha + \beta x + \gamma x^2$ or $\alpha e^{\beta x}$. To estimate $E(Y) = \mu(x)$, or equivalently the parameters α , β , and γ , we observe the random variable Y for each of n possible different values of x , say x_1, x_2, \dots, x_n , which are not all equal. Once the n independent experiments have been performed, we have n pairs of known numbers $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$. These pairs are then used to estimate the mean $E(Y)$. Problems like this are often classified under *regression* because $E(Y) = \mu(x)$ is frequently called a regression curve.

Remark 9.6.1. A model for the mean such as $\alpha + \beta x + \gamma x^2$ is called a **linear model** because it is linear in the parameters α , β , and γ . Thus $\alpha e^{\beta x}$ is not a linear model because it is not linear in α and β . Note that, in Sections 9.2 to 9.5, all the means were linear in the parameters and hence are linear models. ■

For the most part in this section, we consider the case in which $E(Y) = \mu(x)$ is a linear function. Denote by Y_i the response at x_i and consider the model

$$Y_i = \alpha + \beta(x_i - \bar{x}) + e_i, \quad i = 1, \dots, n, \quad (9.6.1)$$

where $\bar{x} = n^{-1} \sum_{i=1}^n x_i$ and e_1, \dots, e_n are iid random variables with a common $N(0, \sigma^2)$ distribution. Hence $E(Y_i) = \alpha + \beta(x_i - \bar{x})$, $\text{Var}(Y_i) = \sigma^2$, and Y_i has $N(\alpha + \beta(x_i - \bar{x}), \sigma^2)$ distribution. The major assumption is that the random errors, e_i , are iid. In particular, this means that the errors are not a function of the x_i 's. This is discussed in Remark 9.6.3. First, we discuss the maximum likelihood estimates of the parameters α , β , and σ .

9.6.1 Maximum Likelihood Estimates

Assume that the n points $(x_1, Y_1), (x_2, Y_2), \dots, (x_n, Y_n)$ follow Model 9.6.1. So the first problem is that of fitting a straight line to the set of points; i.e., estimating α and β . As an aid to our discussion, Figure 9.6.1 shows a **scatterplot** of 60 observations $(x_1, y_1), \dots, (x_{60}, y_{60})$ simulated from a linear model of the form (9.6.1). Our method of estimation in this section is that of maximum likelihood (mle). The joint pdf of Y_1, \dots, Y_n is the product of the individual probability density functions; that is, the likelihood function equals

$$\begin{aligned} L(\alpha, \beta, \sigma^2) &= \prod_{i=1}^n \frac{1}{\sqrt{2\pi\sigma^2}} \exp \left\{ -\frac{[y_i - \alpha - \beta(x_i - \bar{x})]^2}{2\sigma^2} \right\} \\ &= \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \exp \left\{ -\frac{1}{2\sigma^2} \sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})]^2 \right\}. \end{aligned}$$

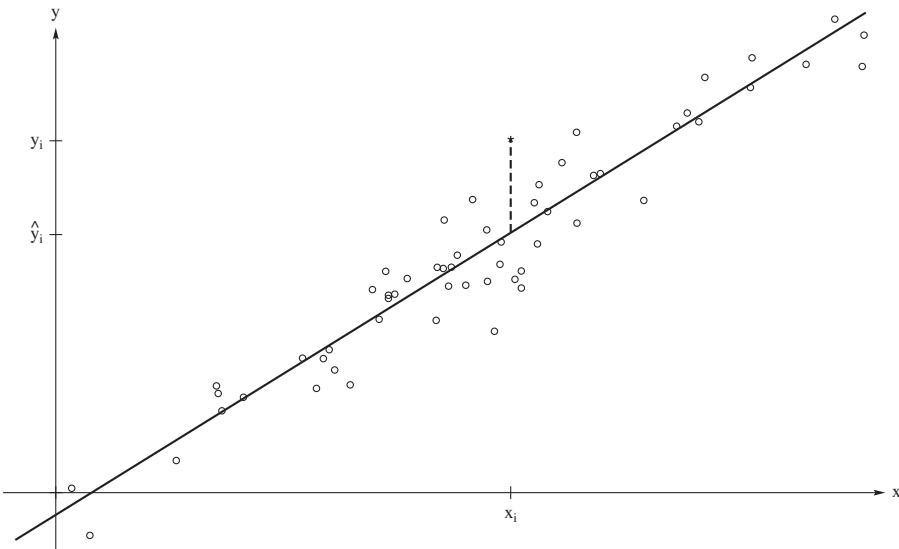

Figure 9.6.1: The plot shows the least squares fitted line (solid line) to a set of data. The dashed-line segment from (x_i, \hat{y}_i) to (x_i, y_i) shows the deviation of (x_i, y_i) from its fit.

To maximize $L(\alpha, \beta, \sigma^2)$, or, equivalently, to minimize

$$-\log L(\alpha, \beta, \sigma^2) = \frac{n}{2} \log(2\pi\sigma^2) + \frac{\sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})]^2}{2\sigma^2},$$

we must select α and β to minimize

$$H(\alpha, \beta) = \sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})]^2.$$

Since $|y_i - \alpha - \beta(x_i - \bar{x})| = |y_i - \mu(x_i)|$ is the vertical distance from the point (x_i, y_i) to the line $y = \mu(x)$ (see the dashed-line segment in Figure 9.6.1), we note that $H(\alpha, \beta)$ represents the sum of the squares of those distances. Thus, selecting α and β so that the sum of the squares is minimized means that we are fitting the straight line to the data by the **method of least squares** (LS).

To minimize $H(\alpha, \beta)$, we find the two first partial derivatives,

$$\frac{\partial H(\alpha, \beta)}{\partial \alpha} = 2 \sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})](-1)$$

and

$$\frac{\partial H(\alpha, \beta)}{\partial \beta} = 2 \sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})][-(x_i - \bar{x})].$$

Setting $\partial H(\alpha, \beta)/\partial\alpha = 0$, we obtain

$$\sum_{i=1}^n y_i - n\alpha - \beta \sum_{i=1}^n (x_i - \bar{x}) = 0. \quad (9.6.2)$$

Since $\sum_{i=1}^n (x_i - \bar{x}) = 0$, the equation becomes $\sum_{i=1}^n y_i - n\alpha = 0$; hence, the mle of α is

$$\hat{\alpha} = \bar{Y}. \quad (9.6.3)$$

The equation $\partial H(\alpha, \beta)/\partial\beta = 0$ yields, with α replaced by \bar{y} ,

$$\sum_{i=1}^n (y_i - \bar{y})(x_i - \bar{x}) - \beta \sum_{i=1}^n (x_i - \bar{x})^2 = 0 \quad (9.6.4)$$

and, hence, the mle of β is

$$\hat{\beta} = \frac{\sum_{i=1}^n (Y_i - \bar{Y})(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n Y_i(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2}. \quad (9.6.5)$$

Equations (9.6.2) and (9.6.4) are the estimating equations for the LS solutions for this simple linear model.

The **fitted value** at the point (x_i, y_i) is given by

$$\hat{y}_i = \hat{\alpha} + \hat{\beta}(x_i - \bar{x}), \quad (9.6.6)$$

which is shown on Figure 9.6.1. The fitted value \hat{y}_i is also called the **predicted value** of y_i at x_i . The **residual** at the point (x_i, y_i) is given by

$$\hat{e}_i = y_i - \hat{y}_i, \quad (9.6.7)$$

which is also shown on Figure 9.6.1. Residual means “what is left” and the residual in regression is exactly that, i.e., what is left over after the fit. The relationship between the fitted values and the residuals are explored in Remark 9.6.3 and in Exercise 9.6.13.

To find the maximum likelihood estimator of σ^2 , consider the partial derivative

$$\frac{\partial[-\log L(\alpha, \beta, \sigma^2)]}{\partial(\sigma^2)} = \frac{n}{2\sigma^2} - \frac{\sum_{i=1}^n [y_i - \alpha - \beta(x_i - \bar{x})]^2}{2(\sigma^2)^2}.$$

Setting this equal to zero and replacing α and β by their solutions $\hat{\alpha}$ and $\hat{\beta}$, we obtain

$$\hat{\sigma}^2 = \frac{1}{n} \sum_{i=1}^n [Y_i - \hat{\alpha} - \hat{\beta}(x_i - \bar{x})]^2. \quad (9.6.8)$$

Of course, due to the invariance of mles, $\hat{\sigma} = \sqrt{\hat{\sigma}^2}$. Note that in terms of the residuals, $\hat{\sigma}^2 = n^{-1} \sum_{i=1}^n \hat{e}_i^2$. As shown in Exercise 9.6.13, the average of the residuals is 0.

Since $\hat{\alpha}$ is a linear function of independent and normally distributed random variables, $\hat{\alpha}$ has a normal distribution with mean

$$E(\hat{\alpha}) = E\left(\frac{1}{n} \sum_{i=1}^n Y_i\right) = \frac{1}{n} \sum_{i=1}^n E(Y_i) = \frac{1}{n} \sum_{i=1}^n [\alpha + \beta(x_i - \bar{x})] = \alpha$$

and variance

$$\text{var}(\hat{\alpha}) = \sum_{i=1}^n \left(\frac{1}{n}\right)^2 \text{var}(Y_i) = \frac{\sigma^2}{n}.$$

The estimator $\hat{\beta}$ is also a linear function of Y_1, Y_2, \dots, Y_n and hence has a normal distribution with mean

$$\begin{aligned} E(\hat{\beta}) &= \frac{\sum_{i=1}^n (x_i - \bar{x})[\alpha + \beta(x_i - \bar{x})]}{\sum_{i=1}^n (x_i - \bar{x})^2} \\ &= \frac{\alpha \sum_{i=1}^n (x_i - \bar{x}) + \beta \sum_{i=1}^n (x_i - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} = \beta \end{aligned}$$

and variance

$$\begin{aligned} \text{var}(\hat{\beta}) &= \sum_{i=1}^n \left[\frac{x_i - \bar{x}}{\sum_{i=1}^n (x_i - \bar{x})^2} \right]^2 \text{var}(Y_i) \\ &= \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{[\sum_{i=1}^n (x_i - \bar{x})^2]^2} \sigma^2 = \frac{\sigma^2}{\sum_{i=1}^n (x_i - \bar{x})^2}. \end{aligned}$$

In summary, the estimators $\hat{\alpha}$ and $\hat{\beta}$ are linear functions of the independent normal random variables Y_1, \dots, Y_n . In Exercise 9.6.4 it is further shown that the covariance between $\hat{\alpha}$ and $\hat{\beta}$ is zero. It follows that $\hat{\alpha}$ and $\hat{\beta}$ are independent random variables with a bivariate normal distribution; that is,

$$\begin{pmatrix} \hat{\alpha} \\ \hat{\beta} \end{pmatrix} \text{ has a } N_2 \left(\begin{pmatrix} \alpha \\ \beta \end{pmatrix}, \sigma^2 \begin{bmatrix} \frac{1}{n} & 0 \\ 0 & \frac{1}{\sum_{i=1}^n (x_i - \bar{x})^2} \end{bmatrix} \right) \text{ distribution.} \quad (9.6.9)$$

Next, we consider the estimator of σ^2 . It can be shown (Exercise 9.6.9) that

$$\begin{aligned} \sum_{i=1}^n [Y_i - \alpha - \beta(x_i - \bar{x})]^2 &= \sum_{i=1}^n \{(\hat{\alpha} - \alpha) + (\hat{\beta} - \beta)(x_i - \bar{x}) \\ &\quad + [Y_i - \hat{\alpha} - \hat{\beta}(x_i - \bar{x})]\}^2 \\ &= n(\hat{\alpha} - \alpha)^2 + (\hat{\beta} - \beta)^2 \sum_{i=1}^n (x_i - \bar{x})^2 + n\hat{\sigma}^2, \end{aligned}$$

or for brevity,

$$Q = Q_1 + Q_2 + Q_3.$$

Here Q, Q_1, Q_2 , and Q_3 are real quadratic forms in the variables

$$Y_i - \alpha - \beta(x_i - \bar{x}), \quad i = 1, 2, \dots, n.$$

In this equation, Q represents the sum of the squares of n independent random variables that have normal distributions with means zero and variances σ^2 . Thus Q/σ^2 has a χ^2 distribution with n degrees of freedom. Each of the random variables $\sqrt{n}(\hat{\alpha} - \alpha)/\sigma$ and $\sqrt{\sum_{i=1}^n(x_i - \bar{x})^2}(\hat{\beta} - \beta)/\sigma$ has a normal distribution with zero mean and unit variance; thus, each of Q_1/σ^2 and Q_2/σ^2 has a χ^2 distribution with 1 degree of freedom. In accordance with Theorem 9.9.2 (proved in Section 9.9), because Q_3 is nonnegative, we have that Q_1 , Q_2 , and Q_3 are independent and that Q_3/σ^2 has a χ^2 distribution with $n - 1 - 1 = n - 2$ degrees of freedom. That is, $n\hat{\sigma}^2/\sigma^2$ has a χ^2 distribution with $n - 2$ degrees of freedom.

We now extend this discussion to obtain inference for the parameters α and β . It follows from the above derivations that both the random variable T_1

$$T_1 = \frac{[\sqrt{n}(\hat{\alpha} - \alpha)]/\sigma}{\sqrt{Q_3/[\sigma^2(n-2)]}} = \frac{\hat{\alpha} - \alpha}{\sqrt{\hat{\sigma}^2/(n-2)}}$$

and the random variable T_2

$$T_2 = \frac{\left[\sqrt{\sum_{i=1}^n(x_i - \bar{x})^2}(\hat{\beta} - \beta)\right]/\sigma}{\sqrt{Q_3/[\sigma^2(n-2)]}} = \frac{\hat{\beta} - \beta}{\sqrt{n\hat{\sigma}^2/[(n-2)\sum_{i=1}^n(x_i - \bar{x})^2]}} \quad (9.6.10)$$

have a t -distribution with $n - 2$ degrees of freedom. These facts enable us to obtain confidence intervals for α and β ; see Exercise 9.6.5. The fact that $n\hat{\sigma}^2/\sigma^2$ has a χ^2 distribution with $n - 2$ degrees of freedom provides a means of determining a confidence interval for σ^2 . These are some of the statistical inferences about the parameters to which reference was made in the introductory remarks of this section.

Remark 9.6.2. The more discerning reader should quite properly question our construction of T_1 and T_2 immediately above. We know that the *squares* of the linear forms are independent of $Q_3 = n\hat{\sigma}^2$, but we do not know, at this time, that the linear forms themselves enjoy this independence. A more general result is obtained in Theorem 9.9.1 of Section 9.9 and the present case is a special instance. ■

Before considering a numerical example, we discuss a diagnostic plot for the major assumption of Model 9.6.1.

Remark 9.6.3 (Diagnostic Plot Based on Fitted Values and Residuals). The major assumption in the model is that the random errors e_1, \dots, e_n are iid. In particular, this means that the errors are not a function of the x_i 's so that a plot of e_i versus $\alpha + \beta(x_i - \bar{x})$ should result in a random scatter. Since the errors and the parameters are unknown this plot is not possible. We have estimates, though, of these quantities, namely the residuals \hat{e}_i and the fitted values \hat{y}_i . A diagnostic for the assumption is to plot the residuals versus the fitted values. This is called the **residual plot**. If the plot results in a random scatter, it is an indication that the model is appropriate. Patterns in the plot, though, are indicative of a poor model. Often in this later case, the patterns in the plot lead to better models. ■

As a final note, in Model 9.6.1 we have centered the x 's; i.e., subtracted \bar{x} from x_i . In practice, usually we do not precenter the x 's. Instead, we fit the model $y_i = \alpha^* + \beta x_i + e_i$. In this case, the least squares, and hence, mles minimize the sum of squares

$$\sum_{i=1}^n (y_i - \alpha^* - \beta x_i)^2. \quad (9.6.11)$$

In Exercise 9.6.1, the reader is asked to show that the estimate of β remains the same as in expression (9.6.5), while $\hat{\alpha}^* = \bar{y} - \hat{\beta}\bar{x}$. We use this noncentered model in the following example.

Example 9.6.1 (Men's 1500 meters). As a numerical illustration, consider data drawn from the Olympics. The response of interest is the winning time of the men's 1500 meters, while the predictor is the year of the olympics. The data were taken from Wikipedia and can be found in `olymp1500mara.rda`. Assume the R vectors for the winning times and year are `time` and `year`, respectively. There are $n = 27$ data points. The top panel of Figure 9.6.2 shows a scatterplot of the data that is computed by the R command

```
par(mfrow=c(2,1)); plot(time~year, xlab="Year", ylab="Winning time")
```

The winning times are steadily decreasing over time and, based on this plot, a simple linear model seems reasonable. Obviously the time for 2016 is an outlier but it is the correct time. Before proceeding to inference, though, we check the quality of the fit of the model. The following R commands obtain the least squares fit, overlaying it on the scatterplot in Figure 9.6.2, the fitted values, and the residuals. These are used to obtain the residual plot that is displayed in the bottom panel of 9.6.2.

```
fit <- lm(time~year); abline(fit)
ehat <- fit$resid; yhat <- fit$fitted.values
plot(ehat~yhat, xlab="Fitted values", ylab="Residuals")
```

Recall a “good” fit is indicated by a random scatter in the residual plot. This does not appear to be the case. There is a dependence⁴ between adjacent points over time. This dependence is apparent from the scatterplot too. In a time series course, this dependence would be investigated.

Based on the dependence, the following inference is approximate. The command `summary(fit)` produces the table of coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	12.325411	1.039402	11.858	9.26e-12
year	-0.004376	0.000530	-8.257	1.31e-08

Hence, the prediction equation is $\hat{y} = 12.33 - .0044\text{year}$. Based on the slope estimate, we predict the winning time to drop by 0.004 minutes every year. For a 95% confidence interval for the slope, the t -critical value via R is `qt(.975, 25)` which computes to 2.060. Using the standard error in the summary table, the following R commands compute confidence interval for the slope parameter:

```
err=0.000530*2.060; lb=-0.004376-err; ub=-0.004376+err; ci=c(lb,ub)
```

⁴This dependence is not surprising. The runners race against each other but they also try to beat the Olympic record.

$ci; -0.0054678 \text{--} 0.0032842$

So with approximate confidence 95%, we estimate the drop in winning time to between 0.0032 to 0.0055 minutes per year.

Based on the fit, the predicted winning time for the men's 1500 meters in the 2020 Olympics is

$$\hat{y} = 12.325411 - 0.004376(2020) = 3.486. \quad (9.6.12)$$

Exercise 9.6.8 provides an estimate (predictive interval) of error for this prediction.

■

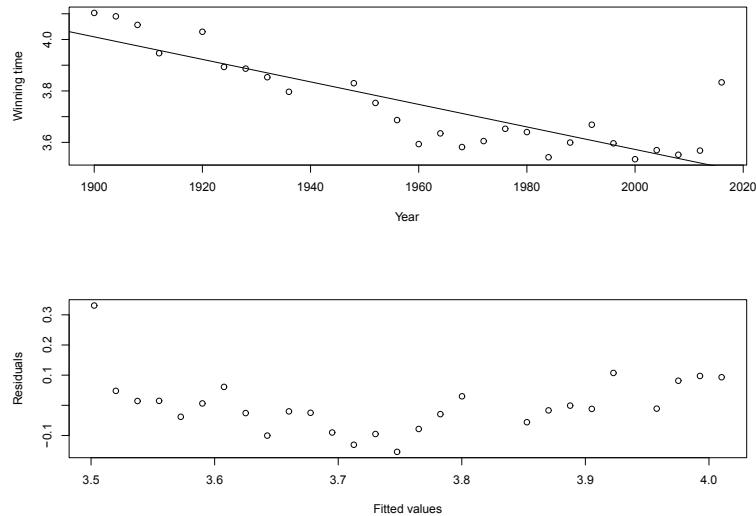

Figure 9.6.2: The top panel is the scatterplot of winning times in the men's 1500 meters versus the year of the Olympics. The least squares fit is overlaid. The bottom panel is the residual plot of the fit.

9.6.2 *Geometry of the Least Squares Fit

In the modern literature, linear models are usually expressed in terms of matrices and vectors, which we briefly introduce in this example. Furthermore, this allows us to discuss the simple geometry behind the least squares fit. Consider then Model (9.6.1). Write the vectors $\mathbf{Y} = (Y_1, \dots, Y_n)', \mathbf{e} = (e_1, \dots, e_n)',$ and $\mathbf{x}_c = (x_1 - \bar{x}, \dots, x_n - \bar{x})'.$ Let $\mathbf{1}$ denote the $n \times 1$ vector whose components are all 1. Then

Model (9.6.1) can be expressed equivalently as

$$\begin{aligned}\mathbf{Y} &= \alpha \mathbf{1} + \beta \mathbf{x}_c + \mathbf{e} \\ &= [\mathbf{1} \ \mathbf{x}_c] \begin{pmatrix} \alpha \\ \beta \end{pmatrix} + \mathbf{e} \\ &= \mathbf{X}\boldsymbol{\beta} + \mathbf{e},\end{aligned}\tag{9.6.13}$$

where \mathbf{X} is the $n \times 2$ matrix with columns $\mathbf{1}$ and \mathbf{x}_c and $\boldsymbol{\beta} = (\alpha, \beta)'$. Next, let $\boldsymbol{\theta} = E(\mathbf{Y}) = \mathbf{X}\boldsymbol{\beta}$. Finally, let V be the two-dimensional subspace of R^n spanned by the columns of \mathbf{X} ; i.e., V is the range of the matrix \mathbf{X} . Hence we can also express the model succinctly as

$$\mathbf{Y} = \boldsymbol{\theta} + \mathbf{e}, \quad \boldsymbol{\theta} \in V.\tag{9.6.14}$$

Hence, except for the random error vector \mathbf{e} , \mathbf{Y} would lie in V . It makes sense intuitively then, as suggested by Figure 9.6.3, to estimate $\boldsymbol{\theta}$ by the vector in V that is “closest” (in Euclidean distance) to \mathbf{Y} , that is, by $\hat{\boldsymbol{\theta}}$, where

$$\hat{\boldsymbol{\theta}} = \operatorname{Argmin}_{\boldsymbol{\theta} \in V} \|\mathbf{Y} - \boldsymbol{\theta}\|^2,\tag{9.6.15}$$

where the square of the **Euclidean norm** is given by $\|\mathbf{u}\|^2 = \sum_{i=1}^n u_i^2$, for $\mathbf{u} \in R^n$. As shown in Exercise 9.6.13 and depicted on the plot in Figure 9.6.3, $\hat{\boldsymbol{\theta}} = \hat{\alpha} \mathbf{1} + \hat{\beta} \mathbf{x}_c$, where $\hat{\alpha}$ and $\hat{\beta}$ are the least squares estimates given above. Also, the vector $\hat{\mathbf{e}} = \mathbf{Y} - \hat{\boldsymbol{\theta}}$ is the vector of residuals and $n\hat{\sigma}^2 = \|\hat{\mathbf{e}}\|^2$. Also, just as depicted in Figure 9.6.3, the angle between the vectors $\hat{\boldsymbol{\theta}}$ and $\hat{\mathbf{e}}$ is a right angle. In linear models, we say that $\hat{\boldsymbol{\theta}}$ is the projection of \mathbf{Y} onto the subspace V .

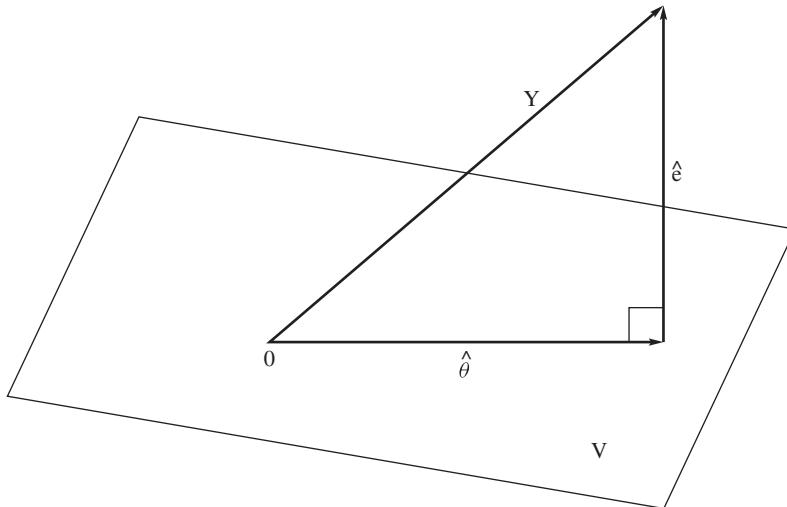

Figure 9.6.3: The sketch shows the geometry of least squares. The vector of responses is \mathbf{Y} , the fit is $\hat{\boldsymbol{\theta}}$, and the vector of residuals is $\hat{\mathbf{e}}$.

EXERCISES

9.6.1. Obtain the least squares estimates for the model $y_i = \alpha^* + \beta x_i + e_i$ by minimizing the sum of squares given in expression (9.6.11). Determine the distribution of $\hat{\alpha}^*$.

9.6.2. Students' scores on the mathematics portion of the ACT examination, x , and on the final examination in the first-semester calculus (200 points possible), y , are:

x	25	20	26	26	28	28	29	32	20	25
y	138	84	104	112	88	132	90	183	100	143
x	26	28	25	31	30					
y	141	161	124	118	168					

The data are also in the rda file `regr1.rda`. Use R or another statistical package for computation and plotting.

- (a) Calculate the least squares regression line for these data.
- (b) Plot the points and the least squares regression line on the same graph.
- (c) Obtain the residual plot and comment on the appropriateness of the model.
- (d) Find 95% confidence interval for β under the usual assumptions. Comment in terms of the problem.

9.6.3 (Telephone Data). Consider the data presented below. The responses (y) for this data set are the numbers of telephone calls (tens of millions) made in Belgium for the years 1950 through 1973. Time, the years, serves as the predictor variable (x). The data are discussed on page 172 of Hettmansperger and McKean (2011) and are in the file `telephone.rda`.

Year	50	51	52	53	54	55
No. Calls	0.44	0.47	0.47	0.59	0.66	0.73
Year	56	57	58	59	60	61
No. Calls	0.81	0.88	1.06	1.20	1.35	1.49
Year	62	63	64	65	66	67
No. Calls	1.61	2.12	11.90	12.40	14.20	15.90
Year	68	69	70	71	72	73
No. Calls	18.20	21.20	4.30	2.40	2.70	2.90

- (a) Calculate the least squares regression line for these data.
- (b) Plot the points and the least squares regression line on the same graph.
- (c) What is the reason for the poor least squares fit?

9.6.4. Show that the covariance between $\hat{\alpha}$ and $\hat{\beta}$ is zero.

9.6.5. Find $(1 - \alpha)100\%$ confidence intervals for the parameters α and β in Model (9.6.1).

9.6.6. Consider Model (9.6.1). Let $\eta_0 = E(Y|x = x_0 - \bar{x})$. The least squares estimator of η_0 is $\hat{\eta}_0 = \hat{\alpha} + \hat{\beta}(x_0 - \bar{x})$.

- (a) Using (9.6.9), show that $\hat{\eta}_0$ is an unbiased estimator and show that its variance is given by

$$V(\hat{\eta}_0) = \sigma^2 \left[\frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} \right]$$

- (b) Obtain the distribution of $\hat{\eta}_0$ and use it to determine a $(1 - \alpha)100\%$ confidence interval for η_0 .

9.6.7. Assume that the sample $(x_1, Y_1), \dots, (x_n, Y_n)$ follows the linear model (9.6.1). Suppose Y_0 is a future observation at $x = x_0 - \bar{x}$ and we want to determine a predictive interval for it. Assume that the model (9.6.1) holds for Y_0 ; i.e., Y_0 has a $N(\alpha + \beta(x_0 - \bar{x}), \sigma^2)$ distribution. We use $\hat{\eta}_0$ of Exercise 9.6.6 as our prediction of Y_0 .

- (a) Obtain the distribution of $Y_0 - \hat{\eta}_0$, showing that its variance is:

$$V(Y_0 - \hat{\eta}_0) = \sigma^2 \left[1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} \right]$$

Use the fact that the future observation Y_0 is independent of the sample $(x_1, Y_1), \dots, (x_n, Y_n)$.

- (b) Determine a t -statistic with numerator $Y_0 - \hat{\eta}_0$.
(c) Now beginning with $1 - \alpha = P[-t_{\alpha/2, n-2} < T < t_{\alpha/2, n-2}]$, where $0 < \alpha < 1$, determine a $(1 - \alpha)100\%$ predictive interval for Y_0 .
(d) Compare this predictive interval with the confidence interval obtained in Exercise 9.6.6. Intuitively, why is the predictive interval larger?

9.6.8. In Example 9.6.1, we obtain the predicted winning time for the men's 1500 meters in the 2020 Olympics. Compute the 95% predictive interval for this prediction that is given in the last exercise. These computations are performed by the R function `cipi.R`. The call is `cipi(lm(time~year), matrix(c(1, 2020), ncol=2))`. In terms of the problem, what does this predictive interval mean? Next compute the prediction for the 2024 and 2028 Olympics. Why are the intervals increasing in length?

9.6.9. Show that

$$\sum_{i=1}^n [Y_i - \alpha - \beta(x_i - \bar{x})]^2 = n(\hat{\alpha} - \alpha)^2 + (\hat{\beta} - \beta)^2 \sum_{i=1}^n (x_i - \bar{x})^2 + \sum_{i=1}^n [Y_i - \hat{\alpha} - \hat{\beta}(x_i - \bar{x})]^2.$$

9.6.10. Let the independent random variables Y_1, Y_2, \dots, Y_n have, respectively, the probability density functions $N(\beta x_i, \gamma^2 x_i^2)$, $i = 1, 2, \dots, n$, where the given numbers x_1, x_2, \dots, x_n are not all equal and no one is zero. Find the maximum likelihood estimators of β and γ^2 .

9.6.11. Let the independent random variables Y_1, \dots, Y_n have the joint pdf

$$L(\alpha, \beta, \sigma^2) = \left(\frac{1}{2\pi\sigma^2} \right)^{n/2} \exp \left\{ -\frac{1}{2\sigma^2} \sum_1^n [y_i - \alpha - \beta(x_i - \bar{x})]^2 \right\},$$

where the given numbers x_1, x_2, \dots, x_n are not all equal. Let $H_0 : \beta = 0$ (α and σ^2 unspecified). It is desired to use a likelihood ratio test to test H_0 against all possible alternatives. Find Λ and see whether the test can be based on a familiar statistic.

Hint: In the notation of this section, show that

$$\sum_1^n (Y_i - \hat{\alpha})^2 = Q_3 + \hat{\beta}^2 \sum_1^n (x_i - \bar{x})^2.$$

9.6.12. Using the notation of Section 9.2, assume that the means μ_j satisfy a linear function of j , namely, $\mu_j = c + d[j - (b+1)/2]$. Let independent random samples of size a be taken from the b normal distributions having means $\mu_1, \mu_2, \dots, \mu_b$, respectively, and common unknown variance σ^2 .

- (a) Show that the maximum likelihood estimators of c and d are, respectively, $\hat{c} = \bar{X}_{..}$ and

$$\hat{d} = \frac{\sum_{j=1}^b [j - (b-1)/2] (\bar{X}_{.j} - \bar{X}_{..})}{\sum_{j=1}^b [j - (b+1)/2]^2}.$$

- (b) Show that

$$\begin{aligned} \sum_{i=1}^a \sum_{j=1}^b (X_{ij} - \bar{X}_{..})^2 &= \sum_{i=1}^a \sum_{j=1}^b \left[X_{ij} - \bar{X}_{..} - \hat{d} \left(j - \frac{b+1}{2} \right) \right]^2 \\ &\quad + \hat{d}^2 \sum_{j=1}^b a \left(j - \frac{b+1}{2} \right)^2. \end{aligned}$$

- (c) Argue that the two terms in the right-hand member of part (b), once divided by σ^2 , are independent random variables with χ^2 distributions provided that $d = 0$.

- (d) What F -statistic would be used to test the equality of the means, that is, $H_0 : d = 0$?

9.6.13. Consider the discussion in Section 9.6.2.

- (a) Show that $\hat{\theta} = \hat{\alpha}\mathbf{1} + \hat{\beta}\mathbf{x}_c$, where $\hat{\alpha}$ and $\hat{\beta}$ are the least squares estimators derived in this section.
- (b) Show that the vector $\hat{\mathbf{e}} = \mathbf{Y} - \hat{\theta}$ is the vector of residuals; i.e., its i th entry is \hat{e}_i , (9.6.7).

- (c) As depicted in Figure 9.6.3, show that the angle between the vectors $\hat{\theta}$ and \hat{e} is a right angle.
- (d) Show that the residuals sum to zero; i.e., $\mathbf{1}'\hat{\mathbf{e}} = 0$.

9.6.14. Fit $y = a + x$ to the data

x	0	1	2
y	1	3	4

by the method of least squares.

9.6.15. Fit by the method of least squares the plane $z = a + bx + cy$ to the five points $(x, y, z) : (-1, -2, 5), (0, -2, 4), (0, 0, 4), (1, 0, 2), (2, 1, 0)$.

Let the R vectors $\mathbf{x}, \mathbf{y}, \mathbf{z}$ contain the values for x, y , and z . Then the LS fit is computed by $\text{lm}(\mathbf{z} \sim \mathbf{x} + \mathbf{y})$.

9.6.16. Let the 4×1 matrix \mathbf{Y} be multivariate normal $N(\mathbf{X}\beta, \sigma^2 \mathbf{I})$, where the 4×3 matrix \mathbf{X} equals

$$\mathbf{X} = \begin{bmatrix} 1 & 1 & 2 \\ 1 & -1 & 2 \\ 1 & 0 & -3 \\ 1 & 0 & -1 \end{bmatrix}$$

and β is the 3×1 regression coefficient matrix.

- (a) Find the mean matrix and the covariance matrix of $\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$.
- (b) If we observe \mathbf{Y}' to be equal to $(6, 1, 11, 3)$, compute $\hat{\beta}$.

9.6.17. Suppose \mathbf{Y} is an $n \times 1$ random vector, \mathbf{X} is an $n \times p$ matrix of known constants of rank p , and β is a $p \times 1$ vector of regression coefficients. Let \mathbf{Y} have a $N(\mathbf{X}\beta, \sigma^2 \mathbf{I})$ distribution. Obtain the pdf of $\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$.

9.6.18. Let the independent normal random variables Y_1, Y_2, \dots, Y_n have, respectively, the probability density functions $N(\mu, \gamma^2 x_i^2)$, $i = 1, 2, \dots, n$, where the given x_1, x_2, \dots, x_n are not all equal and no one of which is zero. Discuss the test of the hypothesis $H_0 : \gamma = 1$, μ unspecified, against all alternatives $H_1 : \gamma \neq 1$, μ unspecified.

9.7 A Test of Independence

Let X and Y have a bivariate normal distribution with means μ_1 and μ_2 , positive variances σ_1^2 and σ_2^2 , and correlation coefficient ρ . We wish to test the hypothesis that X and Y are independent. Because two jointly normally distributed random variables are independent if and only if $\rho = 0$, we test the hypothesis $H_0 : \rho = 0$ against the hypothesis $H_1 : \rho \neq 0$. A likelihood ratio test is used. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ denote a random sample of size $n > 2$ from the

bivariate normal distribution; that is, the joint pdf of these $2n$ random variables is given by

$$f(x_1, y_1) f(x_2, y_2) \cdots f(x_n, y_n).$$

Although it is fairly difficult to show, the statistic that is defined by the likelihood ratio Λ is a function of the statistic, which is the mle of ρ , namely,

$$R = \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^n (X_i - \bar{X})^2 \sum_{i=1}^n (Y_i - \bar{Y})^2}}. \quad (9.7.1)$$

This statistic R is called the sample **correlation coefficient** of the random sample. Following the discussion after expression (5.4.5), the statistic R is a consistent estimate of ρ ; see Exercise 9.7.5. The likelihood ratio principle, which calls for the rejection of H_0 if $\Lambda \leq \lambda_0$, is equivalent to the computed value of $|R| \geq c$. That is, if the absolute value of the correlation coefficient of the sample is too large, we reject the hypothesis that the correlation coefficient of the distribution is equal to zero. To determine a value of c for a satisfactory significance level, it is necessary to obtain the distribution of R , or a function of R , when H_0 is true, as we outline next.

Let $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$, $n > 2$, where x_1, x_2, \dots, x_n and $\bar{x} = \sum_1^n x_i/n$ are fixed numbers such that $\sum_1^n (x_i - \bar{x})^2 > 0$. Consider the conditional pdf of Y_1, Y_2, \dots, Y_n given that $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$. Because Y_1, Y_2, \dots, Y_n are independent and, with $\rho = 0$, are also independent of X_1, X_2, \dots, X_n , this conditional pdf is given by

$$\left(\frac{1}{\sqrt{2\pi}\sigma_2} \right)^n \exp \left\{ -\frac{1}{2\sigma_2^2} \sum_1^n (y_i - \mu_2)^2 \right\}.$$

Let R_c be the correlation coefficient, given $X_1 = x_1, X_2 = x_2, \dots, X_n = x_n$, so that

$$\frac{R_c \sqrt{\sum_{i=1}^n (Y_i - \bar{Y})^2}}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} = \frac{\sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y})}{\sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n (x_i - \bar{x})Y_i}{\sum_{i=1}^n (x_i - \bar{x})^2} \quad (9.7.2)$$

is $\hat{\beta}$, expression (9.6.5) of Section 9.6. Conditionally the mean of Y_i is μ_2 ; i.e., a constant. So here expression (9.7.2) has expectation 0 which implies that $E(R_c) = 0$. Next consider the t -ratio of $\hat{\beta}$ given by T_2 of expression (9.6.10) of Section 9.6. In this notation T_2 can be expressed as

$$T_2 = \frac{R_c \sqrt{\sum (Y_i - \bar{Y})^2} / \sqrt{\sum (x_i - \bar{x})^2}}{\sqrt{\frac{\sum_{i=1}^n \{ Y_i - \bar{Y} - [R_c \sqrt{\sum_{j=1}^n (Y_j - \bar{Y})^2} / \sqrt{\sum_{j=1}^n (x_j - \bar{x})^2}] (x_i - \bar{x}) \}^2}{(n-2) \sum_{j=1}^n (x_j - \bar{x})^2}}} = \frac{R_c \sqrt{n-2}}{\sqrt{1-R_c^2}}. \quad (9.7.3)$$

Thus T_2 , given $X_1 = x_1, \dots, X_n = x_n$, has a conditional t -distribution with $n - 2$ degrees of freedom. Note that the pdf, say $g(t)$, of this t -distribution does not depend upon x_1, x_2, \dots, x_n . Now the joint pdf of X_1, X_2, \dots, X_n and $R\sqrt{n-2}/\sqrt{1-R^2}$, where R is given by expression (9.7.1), is the product of $g(t)$ and the joint pdf of X_1, \dots, X_n . Integration on x_1, \dots, x_n yields the marginal pdf of $R\sqrt{n-2}/\sqrt{1-R^2}$; because $g(t)$ does not depend upon x_1, x_2, \dots, x_n , it is obvious that this marginal pdf is $g(t)$, the conditional pdf of $R\sqrt{n-2}/\sqrt{1-R^2}$. The change-of-variable technique can now be used to find the pdf of R .

Remark 9.7.1. Since R has, when $\rho = 0$, a conditional distribution that does not depend upon x_1, x_2, \dots, x_n (and hence that conditional distribution is, in fact, the marginal distribution of R), we have the remarkable fact that R is independent of X_1, X_2, \dots, X_n . It follows that R is independent of *every function* of X_1, X_2, \dots, X_n alone, that is, a function that does not depend upon any Y_i . In like manner, R is independent of every function of Y_1, Y_2, \dots, Y_n alone. Moreover, a careful review of the argument reveals that nowhere did we use the fact that X has a normal marginal distribution. Thus, if X and Y are independent, and if Y has a normal distribution, then R has the same conditional distribution whatever the distribution of X , subject to the condition $\sum_1^n (x_i - \bar{x})^2 > 0$. Moreover, if $P[\sum_1^n (X_i - \bar{X})^2 > 0] = 1$, then R has the same marginal distribution whatever the distribution of X . ■

If we write $T = R\sqrt{n-2}/\sqrt{1-R^2}$, where T has a t -distribution with $n - 2 > 0$ degrees of freedom, it is easy to show by the change-of-variable technique (Exercise 9.7.4) that the pdf of R is given by

$$h(r) = \begin{cases} \frac{\Gamma[(n-1)/2]}{\Gamma(\frac{1}{2})\Gamma[(n-2)/2]}(1-r^2)^{(n-4)/2} & -1 < r < 1 \\ 0 & \text{elsewhere.} \end{cases} \quad (9.7.4)$$

We have now solved the problem of the distribution of R , when $\rho = 0$ and $n > 2$, or perhaps more conveniently, that of $R\sqrt{n-2}/\sqrt{1-R^2}$. The likelihood ratio test of the hypothesis $H_0 : \rho = 0$ against all alternatives $H_1 : \rho \neq 0$ may be based either on the statistic R or on the statistic $R\sqrt{n-2}/\sqrt{1-R^2} = T$, although the latter is easier to use. Therefore, a level α test is to reject $H_0 : \rho = 0$ if $|T| \geq t_{\alpha/2, n-2}$.

Remark 9.7.2. It is possible to obtain an approximate test of size α by using the fact that

$$W = \frac{1}{2} \log \left(\frac{1+R}{1-R} \right)$$

has an approximate normal distribution with mean $\frac{1}{2} \log[(1+\rho)/(1-\rho)]$ and with variance $1/(n-3)$. We accept this statement without proof. Thus a test of $H_0 : \rho = 0$ can be based on the statistic

$$Z = \frac{\frac{1}{2} \log[(1+R)/(1-R)] - \frac{1}{2} \log[(1+\rho)/(1-\rho)]}{\sqrt{1/(n-3)}}, \quad (9.7.5)$$

with $\rho = 0$ so that $\frac{1}{2} \log[(1 + \rho)/(1 - \rho)] = 0$. However, using W , we can also test a hypothesis like $H_0 : \rho = \rho_0$ against $H_1 : \rho \neq \rho_0$, where ρ_0 is not necessarily zero. In that case, the hypothesized mean of W is

$$\frac{1}{2} \log \left(\frac{1 + \rho_0}{1 - \rho_0} \right).$$

Furthermore, as outlined in Exercise 9.7.6, Z can be used to obtain an asymptotic confidence interval for ρ . ■

EXERCISES

9.7.1. Show that

$$R = \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^n (X_i - \bar{X})^2 \sum_{i=1}^n (Y_i - \bar{Y})^2}} = \frac{\sum_{i=1}^n X_i Y_i - n \bar{X} \bar{Y}}{\sqrt{\left(\sum_{i=1}^n X_i^2 - n \bar{X}^2 \right) \left(\sum_{i=1}^n Y_i^2 - n \bar{Y}^2 \right)}}.$$

9.7.2. A random sample of size $n = 6$ from a bivariate normal distribution yields a value of the correlation coefficient of 0.89. Would we accept or reject, at the 5% significance level, the hypothesis that $\rho = 0$?

9.7.3. Verify Equation (9.7.3) of this section.

9.7.4. Verify the pdf (9.7.4) of this section.

9.7.5. Using the results of Section 4.5, show that R , (9.7.1), is a consistent estimate of ρ .

9.7.6. By doing the following steps, determine a $(1 - \alpha)100\%$ approximate confidence interval for ρ .

- (a) For $0 < \alpha < 1$, in the usual way, start with $1 - \alpha = P(-z_{\alpha/2} < Z < z_{\alpha/2})$, where Z is given by expression (9.7.5). Then isolate $h(\rho) = (1/2) \log [(1 + \rho)/(1 - \rho)]$ in the middle part of the inequality. Find $h'(\rho)$ and show that it is strictly positive on $-1 < \rho < 1$; hence, h is strictly increasing and its inverse function exists.
- (b) Show that this inverse function is the hyperbolic tangent function given by $\tanh(y) = (e^y - e^{-y})/(e^y + e^{-y})$.
- (c) Obtain a $(1 - \alpha)100\%$ confidence interval for ρ .

9.7.7. The intrinsic R function `cor.test(x,y)` computes the estimate of ρ and the confidence interval in Exercise 9.7.6. Recall the baseball data which is in the file `bb.rda`.

- (a) Using the baseball data, determine the estimate and the confidence interval for the correlation coefficient between height and weight for professional baseball players.
- (b) Separate the pitchers and hitters and for each obtain the estimate and confidence for the correlation coefficient between height and weight. Do they differ significantly?
- (c) Argue that the difference in the estimates of the correlation coefficients is the mle of $\rho_1 - \rho_2$ for two independent samples, as in Part (b).

9.7.8. Two experiments gave the following results:

n	\bar{x}	\bar{y}	s_x	s_y	r
100	10	20	5	8	0.70
200	12	22	6	10	0.80

Calculate r for the combined sample.

9.8 The Distributions of Certain Quadratic Forms

Remark 9.8.1. It is essential that the reader have the background of the multivariate normal distribution as given in Section 3.5 to understand Sections 9.8 and 9.9. ■

Remark 9.8.2. We make use of the **trace** of a square matrix. If $\mathbf{A} = [a_{ij}]$ is an $n \times n$ matrix, then we define the trace of \mathbf{A} , ($\text{tr } \mathbf{A}$), to be the sum of its diagonal entries; i.e.,

$$\text{tr } \mathbf{A} = \sum_{i=1}^n a_{ii}. \quad (9.8.1)$$

The trace of a matrix has several interesting properties. One is that it is a linear operator; that is,

$$\text{tr}(a\mathbf{A} + b\mathbf{B}) = a \text{tr } \mathbf{A} + b \text{tr } \mathbf{B}. \quad (9.8.2)$$

A second useful property is: If \mathbf{A} is an $n \times m$ matrix, \mathbf{B} is an $m \times k$ matrix, and \mathbf{C} is a $k \times n$ matrix, then

$$\text{tr } (\mathbf{ABC}) = \text{tr } (\mathbf{BCA}) = \text{tr } (\mathbf{CAB}). \quad (9.8.3)$$

The reader is asked to prove these facts in Exercise 9.8.7. Finally, a simple but useful property is that $\text{tr } a = a$, for any scalar a . ■

We begin this section with a more formal but equivalent definition of a quadratic form. Let $\mathbf{X} = (X_1, \dots, X_n)$ be an n -dimensional random vector and let \mathbf{A} be a real $n \times n$ symmetric matrix. Then the random variable $Q = \mathbf{X}'\mathbf{AX}$ is called a

quadratic form in \mathbf{X} . Due to the symmetry of \mathbf{A} , there are several ways we can write Q :

$$Q = \mathbf{X}'\mathbf{AX} = \sum_{i=1}^n \sum_{j=1}^n a_{ij} X_i X_j = \sum_{i=1}^n a_{ii} X_i^2 + \sum_{i \neq j} a_{ij} X_i X_j \quad (9.8.4)$$

$$= \sum_{i=1}^n a_{ii} X_i^2 + 2 \sum_{i < j} a_{ij} X_i X_j. \quad (9.8.5)$$

These are very useful random variables in analysis of variance models. As the following theorem shows, the mean of a quadratic form is easily obtained.

Theorem 9.8.1. Suppose the n -dimensional random vector \mathbf{X} has mean $\boldsymbol{\mu}$ and variance-covariance matrix $\boldsymbol{\Sigma}$. Let $Q = \mathbf{X}'\mathbf{AX}$, where \mathbf{A} is a real $n \times n$ symmetric matrix. Then

$$E(Q) = \text{tr } \mathbf{A}\boldsymbol{\Sigma} + \boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu}. \quad (9.8.6)$$

Proof: Using the trace operator and property (9.8.3), we have

$$\begin{aligned} E(Q) = E(\text{tr } \mathbf{X}'\mathbf{AX}) &= E(\text{tr } \mathbf{AXX}') \\ &= \text{tr } \mathbf{A} E(\mathbf{XX}') \\ &= \text{tr } \mathbf{A} (\boldsymbol{\Sigma} + \boldsymbol{\mu}\boldsymbol{\mu}') \\ &= \text{tr } \mathbf{A}\boldsymbol{\Sigma} + \boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu}, \end{aligned}$$

where the third line follows from Theorem 2.6.3. ■

Example 9.8.1 (Sample Variance). Let $\mathbf{X}' = (X_1, \dots, X_n)$ be an n -dimensional vector of random variables. Let $\mathbf{1}' = (1, \dots, 1)$ be the n -dimensional vector whose components are 1. Let \mathbf{I} be the $n \times n$ identity matrix. Consider the quadratic form $Q = \mathbf{X}'(\mathbf{I} - \frac{1}{n}\mathbf{J})\mathbf{X}$, where $\mathbf{J} = \mathbf{1}\mathbf{1}'$; i.e., \mathbf{J} is an $n \times n$ matrix with all entries equal to 1. Note that the off-diagonal entries of $(\mathbf{I} - \frac{1}{n}\mathbf{J})$ are $-n^{-1}$ while the diagonal entries are $1 - n^{-1}$; hence, by (9.8.4), Q simplifies to

$$\begin{aligned} Q &= \sum_{i=1}^n X_i^2 \left(1 - \frac{1}{n}\right) + \sum_{i \neq j} \left(-\frac{1}{n}\right) X_i X_j \\ &= \sum_{i=1}^n X_i^2 \left(1 - \frac{1}{n}\right) - \frac{1}{n} \sum_{i=1}^n X_i \sum_{j=1}^n X_j + \frac{1}{n} \sum_{i=1}^n X_i^2 \\ &= \sum_{i=1}^n X_i^2 - n\bar{X}^2 = (n-1)S^2, \end{aligned} \quad (9.8.7)$$

where \bar{X} and S^2 denote the sample mean and variance of X_1, \dots, X_n .

Suppose we further assume that X_1, \dots, X_n are iid random variables with common mean μ and variance σ^2 . Using Theorem 9.8.1, we can obtain yet another

proof that S^2 is an unbiased estimate of σ^2 . Note that the mean of the random vector \mathbf{X} is $\mu\mathbf{1}$ and that its variance–covariance matrix is $\sigma^2\mathbf{I}$. Based on Theorem 9.8.1, we find immediately that

$$E(S^2) = \frac{1}{n-1} \left\{ \text{tr} \left(\mathbf{I} - \frac{1}{n}\mathbf{J} \right) \sigma^2\mathbf{I} + \mu^2 \left(\mathbf{1}'\mathbf{1} - \frac{1}{n}\mathbf{1}'\mathbf{1}\mathbf{1}'\mathbf{1} \right) \right\} = \sigma^2 . \quad \blacksquare$$

The spectral decomposition of symmetric matrices proves quite useful in this part of the chapter. As discussed around expression (3.5.8), a real symmetric matrix \mathbf{A} can be diagonalized as

$$\mathbf{A} = \mathbf{\Gamma}'\mathbf{\Lambda}\mathbf{\Gamma}, \quad (9.8.8)$$

where $\mathbf{\Lambda}$ is the diagonal matrix $\mathbf{\Lambda} = \text{diag}(\lambda_1, \dots, \lambda_n)$, $\lambda_1 \geq \dots \geq \lambda_n$ are the eigenvalues of \mathbf{A} , and the columns of $\mathbf{\Gamma}' = [\mathbf{v}_1 \cdots \mathbf{v}_n]$ are the corresponding orthonormal eigenvectors (i.e., $\mathbf{\Gamma}$ is an orthogonal matrix). Recall from linear algebra that the rank of \mathbf{A} is the number of nonzero eigenvalues. Further, because $\mathbf{\Lambda}$ is diagonal, we can write this expression as

$$\mathbf{A} = \sum_{i=1}^n \lambda_i \mathbf{v}_i \mathbf{v}_i'. \quad (9.8.9)$$

The R command to compute the spectral decomposition of \mathbf{A} is `sdc=eigen(amat)`, where `amat` is the R matrix for \mathbf{A} . The eigenvalues and eigenvectors are in the respective attributes `sdc$values` and `sdc$vectors`. For normal random variables, we make use of equation (9.8.9) to obtain the mgf of the quadratic form Q in the next theorem, Theorem 9.8.2.

Theorem 9.8.2. *Let $\mathbf{X}' = (X_1, \dots, X_n)$, where X_1, \dots, X_n are iid $N(0, \sigma^2)$. Consider the quadratic form $Q = \sigma^{-2}\mathbf{X}'\mathbf{A}\mathbf{X}$ for a symmetric matrix \mathbf{A} of rank $r \leq n$. Then Q has the moment generating function*

$$M(t) = \prod_{i=1}^r (1 - 2t\lambda_i)^{-1/2} = |\mathbf{I} - 2t\mathbf{A}|^{-1/2}, \quad (9.8.10)$$

where $\lambda_1, \dots, \lambda_r$ are the nonzero eigenvalues of \mathbf{A} , $|t| < 1/(2\lambda^*)$, and the value of λ^* is given by $\lambda^* = \max_{1 \leq i \leq r} |\lambda_i|$.

Proof: Write the spectral decomposition of \mathbf{A} as in expression (9.8.9). Since the rank of \mathbf{A} is r , exactly r of the eigenvalues are not 0. Denote the nonzero eigenvalues by $\lambda_1, \dots, \lambda_r$. Then we can write Q as

$$Q = \sum_{i=1}^r \lambda_i (\sigma^{-1}\mathbf{v}_i'\mathbf{X})^2. \quad (9.8.11)$$

Let $\mathbf{\Gamma}'_1 = [\mathbf{v}_1 \cdots \mathbf{v}_r]$ and define the r -dimensional random vector \mathbf{W} by $\mathbf{W} = \sigma^{-1}\mathbf{\Gamma}'_1\mathbf{X}$. Since \mathbf{X} is $N_n(\mathbf{0}, \sigma^2\mathbf{I}_n)$ and $\mathbf{\Gamma}'_1\mathbf{\Gamma}_1 = \mathbf{I}_r$, Theorem 3.5.2 shows that \mathbf{W} has a $N_r(\mathbf{0}, \mathbf{I}_r)$ distribution. In terms of the W_i , we can write (9.8.11) as

$$Q = \sum_{i=1}^r \lambda_i W_i^2. \quad (9.8.12)$$

Because W_1, \dots, W_r are independent $N(0, 1)$ random variables, W_1^2, \dots, W_r^2 are independent $\chi^2(1)$ random variables. Thus the mgf of Q is

$$\begin{aligned} E[\exp\{tQ\}] &= E\left[\exp\left\{\sum_{i=1}^r t\lambda_i W_i^2\right\}\right] \\ &= \prod_{i=1}^r E[\exp\{t\lambda_i W_i^2\}] = \prod_{i=1}^r (1 - 2t\lambda_i)^{-1/2}. \end{aligned} \quad (9.8.13)$$

The last equality holds if we assume that $|t| < 1/(2\lambda^*)$, where $\lambda^* = \max_{1 \leq i \leq r} |\lambda_i|$; see Exercise 9.8.6. To obtain the second form in (9.8.10), recall that the determinant of an orthogonal matrix is 1. The result then follows from

$$\begin{aligned} |\mathbf{I} - 2t\mathbf{A}| &= |\boldsymbol{\Gamma}'\boldsymbol{\Gamma} - 2t\boldsymbol{\Gamma}'\mathbf{\Lambda}\boldsymbol{\Gamma}| = |\boldsymbol{\Gamma}'(\mathbf{I} - 2t\mathbf{\Lambda})\boldsymbol{\Gamma}| \\ &= |\mathbf{I} - 2t\mathbf{\Lambda}| = \left\{ \prod_{i=1}^r (1 - 2t\lambda_i)^{-1/2} \right\}^{-2}. \quad \blacksquare \end{aligned}$$

Example 9.8.2. To illustrate this theorem, suppose X_i , $i = 1, 2, \dots, n$, are independent random variables with X_i distributed as $N(\mu_i, \sigma_i^2)$, $i = 1, 2, \dots, n$, respectively. Let $Z_i = (X_i - \mu_i)/\sigma_i$. We know that $\sum_{i=1}^n Z_i^2$ has a χ^2 distribution with n degrees of freedom. To illustrate Theorem 9.8.2, let $\mathbf{Z}' = (Z_1, \dots, Z_n)$. Let $Q = \mathbf{Z}'\mathbf{I}\mathbf{Z}$. Hence the symmetric matrix associated with Q is the identity matrix \mathbf{I} , which has n eigenvalues, all of value 1; i.e., $\lambda_i \equiv 1$. By Theorem 9.8.2, the mgf of Q is $(1 - 2t)^{-n/2}$; i.e., Q is distributed χ^2 with n degrees of freedom. ■

In general, from Theorem 9.8.2, note how close the mgf of the quadratic form Q is to the mgf of a χ^2 distribution. The next two theorems give conditions where this is true.

Theorem 9.8.3. Let $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ have a $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ distribution, where $\boldsymbol{\Sigma}$ is positive definite. Then $Q = (\mathbf{X} - \boldsymbol{\mu})'\boldsymbol{\Sigma}^{-1}(\mathbf{X} - \boldsymbol{\mu})$ has a $\chi^2(n)$ distribution.

Proof: Write the spectral decomposition of $\boldsymbol{\Sigma}$ as $\boldsymbol{\Sigma} = \boldsymbol{\Gamma}'\mathbf{\Lambda}\boldsymbol{\Gamma}$, where $\boldsymbol{\Gamma}$ is an orthogonal matrix and $\mathbf{\Lambda} = \text{diag}\{\lambda_1, \dots, \lambda_n\}$ is a diagonal matrix whose diagonal entries are the eigenvalues of $\boldsymbol{\Sigma}$. Because $\boldsymbol{\Sigma}$ is positive definite, all $\lambda_i > 0$. Hence we can write

$$\boldsymbol{\Sigma}^{-1} = \boldsymbol{\Gamma}'\mathbf{\Lambda}^{-1}\boldsymbol{\Gamma} = \boldsymbol{\Gamma}'\mathbf{\Lambda}^{-1/2}\boldsymbol{\Gamma}\boldsymbol{\Gamma}'\mathbf{\Lambda}^{-1/2}\boldsymbol{\Gamma},$$

where $\mathbf{\Lambda}^{-1/2} = \text{diag}\{\lambda_1^{-1/2}, \dots, \lambda_n^{-1/2}\}$. Thus we have

$$Q = \left\{ \mathbf{\Lambda}^{-1/2}\boldsymbol{\Gamma}(\mathbf{X} - \boldsymbol{\mu}) \right\}' \mathbf{I} \left\{ \mathbf{\Lambda}^{-1/2}\boldsymbol{\Gamma}(\mathbf{X} - \boldsymbol{\mu}) \right\}.$$

But by Theorem 3.5.2, it is easy to show that the random vector $\mathbf{\Lambda}^{-1/2}\boldsymbol{\Gamma}(\mathbf{X} - \boldsymbol{\mu})$ has a $N_n(\mathbf{0}, \mathbf{I})$ distribution; hence, Q has a $\chi^2(n)$ distribution. ■

The remarkable fact that the random variable Q in the last theorem is $\chi^2(n)$ stimulates a number of questions about quadratic forms in normally distributed

variables. We would like to treat this problem generally, but limitations of space forbid this, and we find it necessary to restrict ourselves to some special cases; see, for instance, Stapleton (2009) for discussion.

Recall from linear algebra that a symmetric matrix \mathbf{A} is **idempotent** if $\mathbf{A}^2 = \mathbf{A}$. In Section 9.1, we have already met some idempotent matrices. For example, the matrix $\mathbf{I} - \frac{1}{n}\mathbf{J}$ of Example 9.8.1 is idempotent. Idempotent matrices possess some important characteristics. Suppose λ is an eigenvalue of an idempotent matrix \mathbf{A} with corresponding eigenvector \mathbf{v} . Then the following identity is true:

$$\lambda\mathbf{v} = \mathbf{Av} = \mathbf{A}^2\mathbf{v} = \lambda\mathbf{Av} = \lambda^2\mathbf{v}.$$

Hence $\lambda(\lambda - 1)\mathbf{v} = \mathbf{0}$. Since $\mathbf{v} \neq \mathbf{0}$, $\lambda = 0$ or 1. Conversely, if the eigenvalues of a real symmetric matrix are only 0s and 1s then it is idempotent; see Exercise 9.8.10. Thus the rank of an idempotent matrix \mathbf{A} is the number of its eigenvalues which are 1. Denote the spectral decomposition of \mathbf{A} by $\mathbf{A} = \mathbf{\Gamma}\mathbf{\Lambda}\mathbf{\Gamma}'$, where $\mathbf{\Lambda}$ is a diagonal matrix of eigenvalues and $\mathbf{\Gamma}$ is an orthogonal matrix whose columns are the corresponding orthonormal eigenvectors. Because the diagonal entries of $\mathbf{\Lambda}$ are 0 or 1 and $\mathbf{\Gamma}$ is orthogonal, we have

$$\text{tr } \mathbf{A} = \text{tr } \mathbf{\Lambda}\mathbf{\Gamma}\mathbf{\Gamma}' = \text{tr } \mathbf{\Lambda} = \text{rank}(\mathbf{A});$$

i.e., the rank of an idempotent matrix is equal to its trace.

Theorem 9.8.4. *Let $\mathbf{X}' = (X_1, \dots, X_n)$, where X_1, \dots, X_n are iid $N(0, \sigma^2)$. Let $Q = \sigma^{-2}\mathbf{X}'\mathbf{A}\mathbf{X}$ for a symmetric matrix \mathbf{A} with rank r . Then Q has a $\chi^2(r)$ distribution if and only if \mathbf{A} is idempotent.*

Proof: By Theorem 9.8.2, the mgf of Q is

$$M_Q(t) = \prod_{i=1}^r (1 - 2t\lambda_i)^{-1/2}, \quad (9.8.14)$$

where $\lambda_1, \dots, \lambda_r$ are the r nonzero eigenvalues of \mathbf{A} . Suppose, first, that \mathbf{A} is idempotent. Then $\lambda_1 = \dots = \lambda_r = 1$ and the mgf of Q is $M_Q(t) = (1 - 2t)^{-r/2}$; i.e., Q has a $\chi^2(r)$ distribution. Next, suppose Q has a $\chi^2(r)$ distribution. Then for t in a neighborhood of 0, we have the identity

$$\prod_{i=1}^r (1 - 2t\lambda_i)^{-1/2} = (1 - 2t)^{-r/2},$$

which, upon squaring both sides, leads to

$$\prod_{i=1}^r (1 - 2t\lambda_i) = (1 - 2t)^r,$$

By the uniqueness of the factorization of polynomials, $\lambda_1 = \dots = \lambda_r = 1$. Hence \mathbf{A} is idempotent. ■

Example 9.8.3. Based on this last theorem, we can obtain quickly the distribution of the sample variance when sampling from a normal distribution. Suppose X_1, X_2, \dots, X_n are iid $N(\mu, \sigma^2)$. Let $\mathbf{X} = (X_1, X_2, \dots, X_n)'$. Then \mathbf{X} has a $N_n(\mu\mathbf{1}, \sigma^2\mathbf{I})$ distribution, where $\mathbf{1}$ denotes a $n \times 1$ vector with all components equal to 1. Let $S^2 = (n-1)^{-1} \sum_{i=1}^n (X_i - \bar{X})^2$. Then by Example 9.8.1, we can write

$$\frac{(n-1)S^2}{\sigma^2} = \sigma^{-2}\mathbf{X}' \left(\mathbf{I} - \frac{1}{n}\mathbf{J} \right) \mathbf{X} = \sigma^{-2}(\mathbf{X} - \mu\mathbf{1})' \left(\mathbf{I} - \frac{1}{n}\mathbf{J} \right) (\mathbf{X} - \mu\mathbf{1}),$$

where the last equality holds because $(\mathbf{I} - \frac{1}{n}\mathbf{J})\mathbf{1} = \mathbf{0}$. Because the matrix $\mathbf{I} - \frac{1}{n}\mathbf{J}$ is idempotent, $\text{tr}(\mathbf{I} - \frac{1}{n}\mathbf{J}) = n-1$, and $\mathbf{X} - \mu\mathbf{1}$ is $N_n(\mathbf{0}, \sigma^2\mathbf{I})$, it follows from Theorem 9.8.4 that $(n-1)S^2/\sigma^2$ has a $\chi^2(n-1)$ distribution. ■

Remark 9.8.3. If the normal distribution in Theorem 9.8.4 is $N_n(\boldsymbol{\mu}, \sigma^2\mathbf{I})$, the condition $\mathbf{A}^2 = \mathbf{A}$ remains a necessary and sufficient condition that Q/σ^2 have a chi-square distribution. In general, however, Q/σ^2 is not central $\chi^2(r)$ but instead, Q/σ^2 has a noncentral chi-square distribution if $\mathbf{A}^2 = \mathbf{A}$. The number of degrees of freedom is r , the rank of \mathbf{A} , and the noncentrality parameter is $\boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu}/\sigma^2$. If $\boldsymbol{\mu} = \mu\mathbf{1}$, then $\boldsymbol{\mu}'\mathbf{A}\boldsymbol{\mu} = \mu^2 \sum_{i,j} a_{ij}$, where $\mathbf{A} = [a_{ij}]$. Then, if $\mu \neq 0$, the conditions $\mathbf{A}^2 = \mathbf{A}$ and $\sum_{i,j} a_{ij} = 0$ are necessary and sufficient conditions that Q/σ^2

be central $\chi^2(r)$. Moreover, the theorem may be extended to a quadratic form in random variables which have a multivariate normal distribution with positive definite covariance matrix $\boldsymbol{\Sigma}$; here the necessary and sufficient condition that Q have a chi-square distribution is $\mathbf{A}\boldsymbol{\Sigma}\mathbf{A} = \mathbf{A}$. See Exercise 9.8.9. ■

EXERCISES

9.8.1. Let $Q = X_1X_2 - X_3X_4$, where X_1, X_2, X_3, X_4 is a random sample of size 4 from a distribution that is $N(0, \sigma^2)$. Show that Q/σ^2 does not have a chi-square distribution. Find the mgf of Q/σ^2 .

9.8.2. Let $\mathbf{X}' = [X_1, X_2]$ be bivariate normal with matrix of means $\boldsymbol{\mu}' = [\mu_1, \mu_2]$ and positive definite covariance matrix $\boldsymbol{\Sigma}$. Let

$$Q_1 = \frac{X_1^2}{\sigma_1^2(1-\rho^2)} - 2\rho \frac{X_1X_2}{\sigma_1\sigma_2(1-\rho^2)} + \frac{X_2^2}{\sigma_2^2(1-\rho^2)}.$$

Show that Q_1 is $\chi^2(r, \theta)$ and find r and θ . When and only when does Q_1 have a central chi-square distribution?

9.8.3. Let $\mathbf{X}' = [X_1, X_2, X_3]$ denote a random sample of size 3 from a distribution that is $N(4, 8)$ and let

$$\mathbf{A} = \begin{pmatrix} \frac{1}{2} & 0 & \frac{1}{2} \\ 0 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{2} \end{pmatrix}.$$

Let $Q = \mathbf{X}'\mathbf{A}\mathbf{X}/\sigma^2$.

- (a) Use Theorem 9.8.1 to find the $E(Q)$.
 (b) Justify the assertion that Q is $\chi^2(2, 6)$.

9.8.4. Suppose X_1, \dots, X_n are independent random variables with the common mean μ but with unequal variances $\sigma_i^2 = \text{Var}(X_i)$.

- (a) Determine the variance of \bar{X} .
 (b) Determine the constant K so that $Q = K \sum_{i=1}^n (X_i - \bar{X})^2$ is an unbiased estimate of the variance of \bar{X} . (*Hint:* Proceed as in Example 9.8.3.)

9.8.5. Suppose X_1, \dots, X_n are correlated random variables, with common mean μ and variance σ^2 but with correlations ρ (all correlations are the same).

- (a) Determine the variance of \bar{X} .
 (b) Determine the constant K so that $Q = K \sum_{i=1}^n (X_i - \bar{X})^2$ is an unbiased estimate of the variance of \bar{X} . (*Hint:* Proceed as in Example 9.8.3.)

9.8.6. Fill in the details for expression (9.8.13).

9.8.7. For the trace operator defined in expression (9.8.1), prove the following properties are true.

- (a) If \mathbf{A} and \mathbf{B} are $n \times n$ matrices and a and b are scalars, then

$$\text{tr}(a\mathbf{A} + b\mathbf{B}) = a \text{tr}\mathbf{A} + b \text{tr}\mathbf{B}.$$

- (b) If \mathbf{A} is an $n \times m$ matrix, \mathbf{B} is an $m \times k$ matrix, and \mathbf{C} is a $k \times n$ matrix, then

$$\text{tr}(\mathbf{ABC}) = \text{tr}(\mathbf{BCA}) = \text{tr}(\mathbf{CAB}).$$

- (c) If \mathbf{A} is a square matrix and $\mathbf{\Gamma}$ is an orthogonal matrix, use the result of part (a) to show that $\text{tr}(\mathbf{\Gamma}'\mathbf{A}\mathbf{\Gamma}) = \text{tr}\mathbf{A}$.

- (d) If \mathbf{A} is a real symmetric idempotent matrix, use the result of part (b) to prove that the rank of \mathbf{A} is equal to $\text{tr}\mathbf{A}$.

9.8.8. Let $\mathbf{A} = [a_{ij}]$ be a real symmetric matrix. Prove that $\sum_i \sum_j a_{ij}^2$ is equal to the sum of the squares of the eigenvalues of \mathbf{A} .

Hint: If $\mathbf{\Gamma}$ is an orthogonal matrix, show that $\sum_j \sum_i a_{ij}^2 = \text{tr}(\mathbf{A}^2) = \text{tr}(\mathbf{\Gamma}'\mathbf{A}^2\mathbf{\Gamma}) = \text{tr}[(\mathbf{\Gamma}'\mathbf{A}\mathbf{\Gamma})(\mathbf{\Gamma}'\mathbf{A}\mathbf{\Gamma})]$.

9.8.9. Suppose \mathbf{X} has a $N_n(0, \boldsymbol{\Sigma})$ distribution, where $\boldsymbol{\Sigma}$ is positive definite. Let $Q = \mathbf{X}'\mathbf{A}\mathbf{X}$ for a symmetric matrix \mathbf{A} with rank r . Prove Q has a $\chi^2(r)$ distribution if and only if $\mathbf{A}\boldsymbol{\Sigma}\mathbf{A} = \mathbf{A}$.

Hint: Write Q as

$$Q = (\boldsymbol{\Sigma}^{-1/2}\mathbf{X})'\boldsymbol{\Sigma}^{1/2}\mathbf{A}\boldsymbol{\Sigma}^{1/2}(\boldsymbol{\Sigma}^{-1/2}\mathbf{X}),$$

where $\boldsymbol{\Sigma}^{1/2} = \mathbf{\Gamma}'\boldsymbol{\Lambda}^{1/2}\mathbf{\Gamma}$ and $\boldsymbol{\Sigma} = \mathbf{\Gamma}'\boldsymbol{\Lambda}\mathbf{\Gamma}$ is the spectral decomposition of $\boldsymbol{\Sigma}$. Then use Theorem 9.8.4.

9.8.10. Suppose \mathbf{A} is a real symmetric matrix. If the eigenvalues of \mathbf{A} are only 0s and 1s then prove that \mathbf{A} is idempotent.

9.9 The Independence of Certain Quadratic Forms

We have previously investigated the independence of linear functions of normally distributed variables. In this section we shall prove some theorems about the independence of quadratic forms. We shall confine our attention to normally distributed variables that constitute a random sample of size n from a distribution that is $N(0, \sigma^2)$.

Remark 9.9.1. In the proof of the next theorem, we use the fact that if \mathbf{A} is an $m \times n$ matrix of rank n (i.e., \mathbf{A} has full column rank), then the matrix $\mathbf{A}'\mathbf{A}$ is nonsingular. A proof of this linear algebra fact is sketched in Exercises 9.9.12 and 9.9.13. ■

Theorem 9.9.1 (Craig). *Let $\mathbf{X}' = (X_1, \dots, X_n)$, where X_1, \dots, X_n are iid $N(0, \sigma^2)$ random variables. For real symmetric matrices \mathbf{A} and \mathbf{B} , let $Q_1 = \sigma^{-2}\mathbf{X}'\mathbf{A}\mathbf{X}$ and $Q_2 = \sigma^{-2}\mathbf{X}'\mathbf{B}\mathbf{X}$ denote quadratic forms in \mathbf{X} . The random variables Q_1 and Q_2 are independent if and only if $\mathbf{AB} = \mathbf{0}$.*

Proof: First, we obtain some preliminary results. Based on these results, the proof follows immediately. Assume the ranks of the matrices \mathbf{A} and \mathbf{B} are r and s , respectively. Let $\mathbf{\Gamma}'_1 \mathbf{\Lambda}_1 \mathbf{\Gamma}_1$ denote the spectral decomposition of \mathbf{A} . Denote the r nonzero eigenvalues of \mathbf{A} by $\lambda_1, \dots, \lambda_r$. Without loss of generality, assume that these nonzero eigenvalues of \mathbf{A} are the first r elements on the main diagonal of $\mathbf{\Lambda}_1$ and let $\mathbf{\Gamma}'_{11}$ be the $n \times r$ matrix whose columns are the corresponding eigenvectors. Finally, let $\mathbf{\Lambda}_{11} = \text{diag}\{\lambda_1, \dots, \lambda_r\}$. Then we can write the spectral decomposition of \mathbf{A} in either of the two ways

$$\mathbf{A} = \mathbf{\Gamma}'_1 \mathbf{\Lambda}_1 \mathbf{\Gamma}_1 = \mathbf{\Gamma}'_{11} \mathbf{\Lambda}_{11} \mathbf{\Gamma}_{11}. \quad (9.9.1)$$

Note that we can write Q_1 as

$$Q_1 = \sigma^{-2}\mathbf{X}'\mathbf{\Gamma}'_{11}\mathbf{\Lambda}_{11}\mathbf{\Gamma}_{11}\mathbf{X} = \sigma^{-2}(\mathbf{\Gamma}_{11}\mathbf{X})'\mathbf{\Lambda}_{11}(\mathbf{\Gamma}_{11}\mathbf{X}) = \mathbf{W}'_1 \mathbf{\Lambda}_{11} \mathbf{W}_1, \quad (9.9.2)$$

where $\mathbf{W}_1 = \sigma^{-1}\mathbf{\Gamma}_{11}\mathbf{X}$. Next, obtain a similar representation based on the s nonzero eigenvalues $\gamma_1, \dots, \gamma_s$ of \mathbf{B} . Let $\mathbf{\Lambda}_{22} = \text{diag}\{\gamma_1, \dots, \gamma_s\}$ denote the $s \times s$ diagonal matrix of nonzero eigenvalues and form the $n \times s$ matrix $\mathbf{\Gamma}'_{21} = [\mathbf{u}_1 \cdots \mathbf{u}_s]$ of corresponding eigenvectors. Then we can write the spectral decomposition of \mathbf{B} as

$$\mathbf{B} = \mathbf{\Gamma}'_{21} \mathbf{\Lambda}_{22} \mathbf{\Gamma}_{21}. \quad (9.9.3)$$

Also, we can write Q_2 as

$$Q_2 = \mathbf{W}'_2 \mathbf{\Lambda}_{22} \mathbf{W}_2, \quad (9.9.4)$$

where $\mathbf{W}_2 = \sigma^{-1}\mathbf{\Gamma}_{21}\mathbf{X}$. Letting $\mathbf{W}' = (\mathbf{W}'_1, \mathbf{W}'_2)$, we have

$$\mathbf{W} = \sigma^{-1} \begin{bmatrix} \mathbf{\Gamma}_{11} \\ \mathbf{\Gamma}_{21} \end{bmatrix} \mathbf{X}.$$

Because \mathbf{X} has a $N_n(\mathbf{0}, \sigma^2\mathbf{I})$ distribution, Theorem 3.5.2 shows that \mathbf{W} has an $(r+s)$ -dimensional multivariate normal distribution with mean $\mathbf{0}$ and variance-covariance matrix

$$\text{Var}(\mathbf{W}) = \begin{bmatrix} \mathbf{I}_r & \mathbf{\Gamma}_{11}\mathbf{\Gamma}'_{21} \\ \mathbf{\Gamma}_{21}\mathbf{\Gamma}'_{11} & \mathbf{I}_s \end{bmatrix}. \quad (9.9.5)$$

Finally, using (9.9.1) and (9.9.3), we have the identity

$$\mathbf{AB} = \{\boldsymbol{\Gamma}'_{11}\boldsymbol{\Lambda}_{11}\}\boldsymbol{\Gamma}_{11}\boldsymbol{\Gamma}'_{21}\{\boldsymbol{\Lambda}_{22}\boldsymbol{\Gamma}_{21}\}. \quad (9.9.6)$$

Let \mathbf{U} denote the matrix in the first set of braces. Note that \mathbf{U} has full column rank, so its kernel is null; i.e., its kernel consists of the vector $\mathbf{0}$. Let \mathbf{V} denote the matrix in the second set of braces. Note that \mathbf{V} has full row rank, hence the kernel of \mathbf{V}' is null.

For the proof then, suppose $\mathbf{AB} = \mathbf{0}$. Then

$$\mathbf{U}[\boldsymbol{\Gamma}_{11}\boldsymbol{\Gamma}'_{21}\mathbf{V}] = \mathbf{0}.$$

Because the kernel of \mathbf{U} is null this implies each column of the matrix in the brackets is the vector $\mathbf{0}$; i.e., the matrix in the brackets is the matrix $\mathbf{0}$. This implies that

$$\mathbf{V}'[\boldsymbol{\Gamma}_{21}\boldsymbol{\Gamma}'_{11}] = \mathbf{0}.$$

In the same way, because the kernel of \mathbf{V}' is null, we have $\boldsymbol{\Gamma}_{11}\boldsymbol{\Gamma}'_{21} = \mathbf{0}$. Hence, by (9.9.5), the random vectors \mathbf{W}_1 and \mathbf{W}_2 are independent. Therefore, by (9.9.2) and (9.9.4), Q_1 and Q_2 are independent.

Conversely, if Q_1 and Q_2 are independent, then

$$\{E[\exp\{t_1Q_1 + t_2Q_2\}]\}^{-2} = \{E[\exp\{t_1Q_1\}]\}^{-2} \{E[\exp\{t_2Q_2\}]\}^{-2}, \quad (9.9.7)$$

for (t_1, t_2) in an open neighborhood of $(0, 0)$. Note that $t_1Q_1 + t_2Q_2$ is a quadratic form in \mathbf{X} with symmetric matrix $t_1\mathbf{A} + t_2\mathbf{B}$. Recall that the matrix $\boldsymbol{\Gamma}_1$ is orthogonal and hence has determinant ± 1 . Using this and Theorem 9.8.2, we can write the left side of (9.9.7) as

$$\begin{aligned} E^{-2}[\exp\{t_1Q_1 + t_2Q_2\}] &= |\mathbf{I}_n - 2t_1\mathbf{A} - 2t_2\mathbf{B}| \\ &= |\boldsymbol{\Gamma}'_1\boldsymbol{\Gamma}_1 - 2t_1\boldsymbol{\Gamma}'_1\boldsymbol{\Lambda}_1\boldsymbol{\Gamma}_1 - 2t_2\boldsymbol{\Gamma}'_1(\boldsymbol{\Gamma}_1\mathbf{B}\boldsymbol{\Gamma}'_1)\boldsymbol{\Gamma}_1| \\ &= |\mathbf{I}_n - 2t_1\boldsymbol{\Lambda}_1 - 2t_2\mathbf{D}|, \end{aligned} \quad (9.9.8)$$

where the matrix \mathbf{D} is given by

$$\mathbf{D} = \boldsymbol{\Gamma}_1\mathbf{B}\boldsymbol{\Gamma}'_1 = \begin{bmatrix} \mathbf{D}_{11} & \mathbf{D}_{12} \\ \mathbf{D}_{21} & \mathbf{D}_{22} \end{bmatrix}, \quad (9.9.9)$$

and \mathbf{D}_{11} is $r \times r$. By (9.9.2), (9.9.3), and Theorem 9.8.2, the right side of (9.9.7) can be written as

$$\{E[\exp\{t_1Q_1\}]\}^{-2} \{E[\exp\{t_2Q_2\}]\}^{-2} = \left\{ \prod_{i=1}^r (1 - 2t_1\lambda_i) \right\} |\mathbf{I}_n - 2t_2\mathbf{D}|. \quad (9.9.10)$$

This leads to the identity

$$|\mathbf{I}_n - 2t_1\boldsymbol{\Lambda}_1 - 2t_2\mathbf{D}| = \left\{ \prod_{i=1}^r (1 - 2t_1\lambda_i) \right\} |\mathbf{I}_n - 2t_2\mathbf{D}|, \quad (9.9.11)$$

for (t_1, t_2) in an open neighborhood of $(0, 0)$.

The coefficient of $(-2t_1)^r$ on the right side of (9.9.11) is $\lambda_1 \cdots \lambda_r |\mathbf{I} - 2t_2 \mathbf{D}|$. It is not so easy to find the coefficient of $(-2t_1)^r$ in the left side of the equation (9.9.11). Conceive of expanding this determinant in terms of minors of order r formed from the first r columns. One term in this expansion is the product of the minor of order r in the upper left-hand corner, namely, $|\mathbf{I}_r - 2t_1 \mathbf{\Lambda}_{11} - 2t_2 \mathbf{D}_{11}|$, and the minor of order $n - r$ in the lower right-hand corner, namely, $|\mathbf{I}_{n-r} - 2t_2 \mathbf{D}_{22}|$. Moreover, this product is the only term in the expansion of the determinant that involves $(-2t_1)^r$. Thus the coefficient of $(-2t_1)^r$ in the left-hand member of Equation (9.9.11) is $\lambda_1 \cdots \lambda_r |\mathbf{I}_{n-r} - 2t_2 \mathbf{D}_{22}|$. If we equate these coefficients of $(-2t_1)^r$, we have

$$|\mathbf{I} - 2t_2 \mathbf{D}| = |\mathbf{I}_{n-r} - 2t_2 \mathbf{D}_{22}|, \quad (9.9.12)$$

for t_2 in an open neighborhood of 0. Equation (9.9.12) implies that the nonzero eigenvalues of the matrices \mathbf{D} and \mathbf{D}_{22} are the same (see Exercise 9.9.8). Recall that the sum of the squares of the eigenvalues of a symmetric matrix is equal to the sum of the squares of the elements of that matrix (see Exercise 9.8.8). Thus the sum of the squares of the elements of matrix \mathbf{D} is equal to the sum of the squares of the elements of \mathbf{D}_{22} . Since the elements of the matrix \mathbf{D} are real, it follows that each of the elements of $\mathbf{D}_{11}, \mathbf{D}_{12}$, and \mathbf{D}_{21} is zero. Hence we can write

$$\mathbf{0} = \mathbf{\Lambda}_1 \mathbf{D} = \mathbf{\Gamma}_1 \mathbf{A} \mathbf{\Gamma}'_1 \mathbf{\Gamma}_1 \mathbf{B} \mathbf{\Gamma}'_1$$

because $\mathbf{\Gamma}_1$ is an orthogonal matrix, $\mathbf{AB} = \mathbf{0}$. ■

Remark 9.9.2. Theorem 9.9.1 remains valid if the random sample is from a distribution that is $N(\mu, \sigma^2)$, whatever the real value of μ . Moreover, Theorem 9.9.1 may be extended to quadratic forms in random variables that have a joint multivariate normal distribution with a positive definite covariance matrix Σ . The necessary and sufficient condition for the independence of two such quadratic forms with symmetric matrices \mathbf{A} and \mathbf{B} then becomes $\mathbf{A}\Sigma\mathbf{B} = \mathbf{0}$. In our Theorem 9.9.1, we have $\Sigma = \sigma^2 \mathbf{I}$, so that $\mathbf{A}\Sigma\mathbf{B} = \mathbf{A}\sigma^2 \mathbf{IB} = \sigma^2 \mathbf{AB} = \mathbf{0}$. ■

The following theorem is from Hogg and Craig (1958).

Theorem 9.9.2 (Hogg and Craig). *Define the sum $Q = Q_1 + \cdots + Q_{k-1} + Q_k$, where $Q, Q_1, \dots, Q_{k-1}, Q_k$ are $k+1$ random variables that are quadratic forms in the observations of a random sample of size n from a distribution that is $N(0, \sigma^2)$. Let Q/σ^2 be $\chi^2(r)$, let Q_i/σ^2 be $\chi^2(r_i)$, $i = 1, 2, \dots, k-1$, and let Q_k be nonnegative. Then the random variables Q_1, Q_2, \dots, Q_k are independent and, hence, Q_k/σ^2 is $\chi^2(r_k = r - r_1 - \cdots - r_{k-1})$.*

Proof: Take first the case of $k = 2$ and let the real symmetric matrices Q, Q_1 , and Q_2 be denoted, respectively, by $\mathbf{A}, \mathbf{A}_1, \mathbf{A}_2$. We are given that $Q = Q_1 + Q_2$ or, equivalently, that $\mathbf{A} = \mathbf{A}_1 + \mathbf{A}_2$. We are also given that Q/σ^2 is $\chi^2(r)$ and that Q_1/σ^2 is $\chi^2(r_1)$. In accordance with Theorem 9.8.4, we have $\mathbf{A}^2 = \mathbf{A}$ and $\mathbf{A}_1^2 = \mathbf{A}_1$.

Since $Q_2 \geq 0$, each of the matrices \mathbf{A} , \mathbf{A}_1 , and \mathbf{A}_2 is positive semidefinite. Because $\mathbf{A}^2 = \mathbf{A}$, we can find an orthogonal matrix Γ such that

$$\Gamma' \mathbf{A} \Gamma = \begin{bmatrix} \mathbf{I}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}.$$

If we multiply both members of $\mathbf{A} = \mathbf{A}_1 + \mathbf{A}_2$ on the left by Γ' and on the right by Γ , we have

$$\begin{bmatrix} \mathbf{I}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \Gamma' \mathbf{A}_1 \Gamma + \Gamma' \mathbf{A}_2 \Gamma.$$

Now each of \mathbf{A}_1 and \mathbf{A}_2 , and hence each of $\Gamma' \mathbf{A}_1 \Gamma$ and $\Gamma' \mathbf{A}_2 \Gamma$ is positive semidefinite. Recall that if a real symmetric matrix is positive semidefinite, each element on the principal diagonal is positive or zero. Moreover, if an element on the principal diagonal is zero, then all elements in that row and all elements in that column are zero. Thus $\Gamma' \mathbf{A} \Gamma = \Gamma' \mathbf{A}_1 \Gamma + \Gamma' \mathbf{A}_2 \Gamma$ can be written as

$$\begin{bmatrix} \mathbf{I}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{G}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} + \begin{bmatrix} \mathbf{H}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}. \quad (9.9.13)$$

Since $\mathbf{A}_1^2 = \mathbf{A}_1$, we have

$$(\Gamma' \mathbf{A}_1 \Gamma)^2 = \Gamma' \mathbf{A}_1 \Gamma = \begin{bmatrix} \mathbf{G}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}.$$

If we multiply both members of Equation (9.9.13) on the left by the matrix $\Gamma' \mathbf{A}_1 \Gamma$, we see that

$$\begin{bmatrix} \mathbf{G}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{G}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} + \begin{bmatrix} \mathbf{G}_r \mathbf{H}_r & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

or, equivalently, $\Gamma' \mathbf{A}_1 \Gamma = \Gamma' \mathbf{A}_1 \Gamma + (\Gamma' \mathbf{A}_1 \Gamma)(\Gamma' \mathbf{A}_2 \Gamma)$. Thus $(\Gamma' \mathbf{A}_1 \Gamma) \times (\Gamma' \mathbf{A}_2 \Gamma) = \mathbf{0}$ and $\mathbf{A}_1 \mathbf{A}_2 = \mathbf{0}$. In accordance with Theorem 9.9.1, Q_1 and Q_2 are independent. This independence immediately implies that Q_2/σ^2 is $\chi^2(r_2 = r - r_1)$. This completes the proof when $k = 2$. For $k > 2$, the proof may be made by induction. We shall merely indicate how this can be done by using $k = 3$. Take $\mathbf{A} = \mathbf{A}_1 + \mathbf{A}_2 + \mathbf{A}_3$, where $\mathbf{A}^2 = \mathbf{A}$, $\mathbf{A}_1^2 = \mathbf{A}_1$, $\mathbf{A}_2^2 = \mathbf{A}_2$, and \mathbf{A}_3 is positive semidefinite. Write $\mathbf{A} = \mathbf{A}_1 + (\mathbf{A}_2 + \mathbf{A}_3) = \mathbf{A}_1 + \mathbf{B}_1$, say. Now $\mathbf{A}^2 = \mathbf{A}$, $\mathbf{A}_1^2 = \mathbf{A}_1$, and \mathbf{B}_1 is positive semidefinite. In accordance with the case of $k = 2$, we have $\mathbf{A}_1 \mathbf{B}_1 = \mathbf{0}$, so that $\mathbf{B}_1^2 = \mathbf{B}_1$. With $\mathbf{B}_1 = \mathbf{A}_2 + \mathbf{A}_3$, where $\mathbf{B}_1^2 = \mathbf{B}_1$, $\mathbf{A}_2^2 = \mathbf{A}_2$, it follows from the case of $k = 2$ that $\mathbf{A}_2 \mathbf{A}_3 = \mathbf{0}$ and $\mathbf{A}_3^2 = \mathbf{A}_3$. If we regroup by writing $\mathbf{A} = \mathbf{A}_2 + (\mathbf{A}_1 + \mathbf{A}_3)$, we obtain $\mathbf{A}_1 \mathbf{A}_3 = \mathbf{0}$, and so on. ■

Remark 9.9.3. In our statement of Theorem 9.9.2, we took X_1, X_2, \dots, X_n to be observations of a random sample from a distribution that is $N(0, \sigma^2)$. We did this because our proof of Theorem 9.9.1 was restricted to that case. In fact, if Q', Q'_1, \dots, Q'_k are quadratic forms in any normal variables (including multivariate normal variables), if $Q' = Q'_1 + \dots + Q'_k$, if $Q', Q'_1, \dots, Q'_{k-1}$ are central or noncentral chi-square, and if Q'_k is nonnegative, then Q'_1, \dots, Q'_k are independent and Q'_k is either central or noncentral chi-square. ■

This section concludes with a proof of a frequently quoted theorem due to Cochran.

Theorem 9.9.3 (Cochran). *Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(0, \sigma^2)$. Let the sum of the squares of these observations be written in the form*

$$\sum_1^n X_i^2 = Q_1 + Q_2 + \dots + Q_k,$$

where Q_j is a quadratic form in X_1, X_2, \dots, X_n , with matrix \mathbf{A}_j that has rank r_j , $j = 1, 2, \dots, k$. The random variables Q_1, Q_2, \dots, Q_k are independent and Q_j/σ^2 is $\chi^2(r_j)$, $j = 1, 2, \dots, k$, if and only if $\sum_1^k r_j = n$.

Proof. First assume the two conditions $\sum_1^k r_j = n$ and $\sum_1^n X_i^2 = \sum_1^k Q_j$ to be satisfied. The latter equation implies that $\mathbf{I} = \mathbf{A}_1 + \mathbf{A}_2 + \dots + \mathbf{A}_k$. Let $\mathbf{B}_i = \mathbf{I} - \mathbf{A}_i$; that is, \mathbf{B}_i is the sum of the matrices $\mathbf{A}_1, \dots, \mathbf{A}_k$ exclusive of \mathbf{A}_i . Let R_i denote the rank of \mathbf{B}_i . Since the rank of the sum of several matrices is less than or equal to the sum of the ranks, we have $R_i \leq \sum_1^k r_j - r_i = n - r_i$. However, $\mathbf{I} = \mathbf{A}_i + \mathbf{B}_i$, so that $n \leq r_i + R_i$ and $n - r_i \leq R_i$. Hence $R_i = n - r_i$. The eigenvalues of \mathbf{B}_i are the roots of the equation $|\mathbf{B}_i - \lambda\mathbf{I}| = 0$. Since $\mathbf{B}_i = \mathbf{I} - \mathbf{A}_i$, this equation can be written as $|\mathbf{I} - \mathbf{A}_i - \lambda\mathbf{I}| = 0$. Thus we have $|\mathbf{A}_i - (1 - \lambda)\mathbf{I}| = 0$. But each root of the last equation is 1 minus an eigenvalue of \mathbf{A}_i . Since \mathbf{B}_i has exactly $n - R_i = r_i$ eigenvalues that are zero, then \mathbf{A}_i has exactly r_i eigenvalues that are equal to 1. However, r_i is the rank of \mathbf{A}_i . Thus each of the r_i nonzero eigenvalues of \mathbf{A}_i is 1. That is, $\mathbf{A}_i^2 = \mathbf{A}_i$ and thus Q_i/σ^2 has a $\chi^2(r_i)$, for $i = 1, 2, \dots, k$. In accordance with Theorem 9.9.2, the random variables Q_1, Q_2, \dots, Q_k are independent.

To complete the proof of Theorem 9.9.3, take

$$\sum_1^n X_i^2 = Q_1 + Q_2 + \dots + Q_k,$$

let Q_1, Q_2, \dots, Q_k be independent, and let Q_j/σ^2 be $\chi^2(r_j)$, $j = 1, 2, \dots, k$. Then $\sum_1^k Q_j/\sigma^2$ is $\chi^2(\sum_1^k r_j)$. But $\sum_1^k Q_j/\sigma^2 = \sum_1^n X_i^2/\sigma^2$ is $\chi^2(n)$. Thus $\sum_1^k r_j = n$ and the proof is complete. ■

EXERCISES

9.9.1. Let X_1, X_2, X_3 be a random sample from the normal distribution $N(0, \sigma^2)$. Are the quadratic forms $X_1^2 + 3X_1X_2 + X_2^2 + X_1X_3 + X_3^2$ and $X_1^2 - 2X_1X_2 + \frac{2}{3}X_2^2 - 2X_1X_2 - X_3^2$ independent or dependent?

9.9.2. Let X_1, X_2, \dots, X_n denote a random sample of size n from a distribution that is $N(0, \sigma^2)$. Prove that $\sum_1^n X_i^2$ and every quadratic form, that is nonidentically zero in X_1, X_2, \dots, X_n , are dependent.

9.9.3. Let X_1, X_2, X_3, X_4 denote a random sample of size 4 from a distribution that is $N(0, \sigma^2)$. Let $Y = \sum_1^4 a_i X_i$, where a_1, a_2, a_3 , and a_4 are real constants. If Y^2 and $Q = X_1X_2 - X_3X_4$ are independent, determine a_1, a_2, a_3 , and a_4 .

9.9.4. Let \mathbf{A} be the real symmetric matrix of a quadratic form Q in the observations of a random sample of size n from a distribution that is $N(0, \sigma^2)$. Given that Q and the mean \bar{X} of the sample are independent, what can be said of the elements of each row (column) of \mathbf{A} ?

Hint: Are Q and \bar{X}^2 independent?

9.9.5. Let $\mathbf{A}_1, \mathbf{A}_2, \dots, \mathbf{A}_k$ be the matrices of $k > 2$ quadratic forms Q_1, Q_2, \dots, Q_k in the observations of a random sample of size n from a distribution that is $N(0, \sigma^2)$. Prove that the pairwise independence of these forms implies that they are mutually independent.

Hint: Show that $\mathbf{A}_i \mathbf{A}_j = \mathbf{0}$, $i \neq j$, permits $E[\exp(t_1 Q_1 + t_2 Q_2 + \dots + t_k Q_k)]$ to be written as a product of the mgfs of Q_1, Q_2, \dots, Q_k .

9.9.6. Let $\mathbf{X}' = [X_1, X_2, \dots, X_n]$, where X_1, X_2, \dots, X_n are observations of a random sample from a distribution that is $N(0, \sigma^2)$. Let $\mathbf{b}' = [b_1, b_2, \dots, b_n]$ be a real nonzero vector, and let \mathbf{A} be a real symmetric matrix of order n . Prove that the linear form $\mathbf{b}' \mathbf{X}$ and the quadratic form $\mathbf{X}' \mathbf{A} \mathbf{X}$ are independent if and only if $\mathbf{b}' \mathbf{A} = \mathbf{0}$. Use this fact to prove that $\mathbf{b}' \mathbf{X}$ and $\mathbf{X}' \mathbf{A} \mathbf{X}$ are independent if and only if the two quadratic forms $(\mathbf{b}' \mathbf{X})^2 = \mathbf{X}' \mathbf{b} \mathbf{b}' \mathbf{X}$ and $\mathbf{X}' \mathbf{A} \mathbf{X}$ are independent.

9.9.7. Let Q_1 and Q_2 be two nonnegative quadratic forms in the observations of a random sample from a distribution that is $N(0, \sigma^2)$. Show that another quadratic form Q is independent of $Q_1 + Q_2$ if and only if Q is independent of each of Q_1 and Q_2 .

Hint: Consider the orthogonal transformation that diagonalizes the matrix of $Q_1 + Q_2$. After this transformation, what are the forms of the matrices Q, Q_1 and Q_2 if Q and $Q_1 + Q_2$ are independent?

9.9.8. Prove that Equation (9.9.12) of this section implies that the nonzero eigenvalues of the matrices \mathbf{D} and \mathbf{D}_{22} are the same.

Hint: Let $\lambda = 1/(2t_2)$, $t_2 \neq 0$, and show that Equation (9.9.12) is equivalent to $|\mathbf{D} - \lambda \mathbf{I}| = (-\lambda)^r |\mathbf{D}_{22} - \lambda \mathbf{I}_{n-r}|$.

9.9.9. Here Q_1 and Q_2 are quadratic forms in observations of a random sample from $N(0, 1)$. If Q_1 and Q_2 are independent and if $Q_1 + Q_2$ has a chi-square distribution, prove that Q_1 and Q_2 are chi-square variables.

9.9.10. Often in regression the mean of the random variable Y is a linear function of p -values x_1, x_2, \dots, x_p , say $\beta_1 x_1 + \beta_2 x_2 + \dots + \beta_p x_p$, where $\boldsymbol{\beta}' = (\beta_1, \beta_2, \dots, \beta_p)$ are the *regression coefficients*. Suppose that n values, $\mathbf{Y}' = (Y_1, Y_2, \dots, Y_n)$, are observed for the x -values in $\mathbf{X} = [x_{ij}]$, where \mathbf{X} is an $n \times p$ *design matrix* and its i th row is associated with Y_i , $i = 1, 2, \dots, n$. Assume that \mathbf{Y} is multivariate normal with mean $\mathbf{X}\boldsymbol{\beta}$ and variance-covariance matrix $\sigma^2 \mathbf{I}$, where \mathbf{I} is the $n \times n$ identity matrix.

- (a) Note that Y_1, Y_2, \dots, Y_n are independent. Why?
- (b) Since \mathbf{Y} should approximately equal its mean $\mathbf{X}\boldsymbol{\beta}$, we estimate $\boldsymbol{\beta}$ by solving the *normal equations* $\mathbf{X}'\mathbf{Y} = \mathbf{X}'\mathbf{X}\boldsymbol{\beta}$ for $\boldsymbol{\beta}$. Assuming that $\mathbf{X}'\mathbf{X}$ is non-singular, solve the equations to get $\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$. Show that $\hat{\boldsymbol{\beta}}$ has a

multivariate normal distribution with mean β and variance–covariance matrix $\sigma^2(\mathbf{X}'\mathbf{X})^{-1}$.

- (c) Show that

$$(\mathbf{Y} - \mathbf{X}\beta)'(\mathbf{Y} - \mathbf{X}\beta) = (\hat{\beta} - \beta)'(\mathbf{X}'\mathbf{X})(\hat{\beta} - \beta) + (\mathbf{Y} - \mathbf{X}\hat{\beta})'(\mathbf{Y} - \mathbf{X}\hat{\beta}),$$

For the remainder of the exercise, let Q denote the quadratic form on the left side of this expression and Q_1 and Q_2 denote the respective quadratic forms on the right side. Hence, $Q = Q_1 + Q_2$.

- (d) Show that Q_1/σ^2 is $\chi^2(p)$.

- (e) Show that Q_1 and Q_2 are independent.

- (f) Argue that Q_2/σ^2 is $\chi^2(n-p)$.

- (g) Find c so that cQ_1/Q_2 has an F -distribution.

- (h) The fact that a value d can be found so that $P(cQ_1/Q_2 \leq d) = 1 - \alpha$ could be used to find a $100(1 - \alpha)\%$ confidence ellipsoid for β . Explain.

9.9.11. Say that G.P.A. (Y) is thought to be a linear function of a “coded” high school rank (x_2) and a “coded” American College Testing score (x_3), namely, $\beta_1 + \beta_2x_2 + \beta_3x_3$. Note that all x_1 values equal 1. We observe the following five points:

x_1	x_2	x_3	Y
1	1	2	3
1	4	3	6
1	2	2	4
1	4	2	4
1	3	2	4

- (a) Compute $\mathbf{X}'\mathbf{X}$ and $\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{Y}$.

- (b) Compute a 95% confidence ellipsoid for $\beta' = (\beta_1, \beta_2, \beta_3)$. See part (h) of Exercise 9.9.10.

9.9.12. Assume that \mathbf{X} is an $n \times p$ matrix. Then the kernel of \mathbf{X} is defined to be the space $\ker(\mathbf{X}) = \{\mathbf{b} : \mathbf{X}\mathbf{b} = \mathbf{0}\}$.

- (a) Show that $\ker(\mathbf{X})$ is a subspace of R^p .

- (b) The dimension of $\ker(\mathbf{X})$ is called the **nullity** of \mathbf{X} and is denoted by $\nu(\mathbf{X})$. Let $\rho(\mathbf{X})$ denote the rank of \mathbf{X} . A fundamental theorem of linear algebra says that $\rho(\mathbf{X}) + \nu(\mathbf{X}) = p$. Use this to show that if \mathbf{X} has full column rank, then $\ker(\mathbf{X}) = \{\mathbf{0}\}$.

9.9.13. Suppose \mathbf{X} is an $n \times p$ matrix with rank p .

- (a) Show that $\ker(\mathbf{X}'\mathbf{X}) = \ker(\mathbf{X})$.

- (b) Use part (a) and the last exercise to show that if \mathbf{X} has full column rank, then $\mathbf{X}'\mathbf{X}$ is nonsingular.

Chapter 10

Nonparametric and Robust Statistics

10.1 Location Models

In this chapter, we present some nonparametric procedures for the simple location problems. As we shall show, the test procedures associated with these methods are distribution-free under null hypotheses. We also obtain point estimators and confidence intervals associated with these tests. The distributions of the estimators are not distribution-free; hence, we use the term **rank-based** to refer collectively to these procedures. The asymptotic relative efficiencies of these procedures are easily obtained, thus facilitating comparisons among them and procedures that we have discussed in earlier chapters. We also obtain estimators that are asymptotically efficient; that is, they achieve asymptotically the Rao–Cramér bound.

Our purpose is not a rigorous development of these concepts, and at times we simply sketch the theory. A rigorous treatment can be found in several advanced texts, such as Randles and Wolfe (1979) or Hettmansperger and McKean (2011). For an applied discussion using R, see Kloke and McKean (2014).

In this and the following section, we consider the one-sample problem. For the most part, we consider continuous random variables X with cdf and pdf $F_X(x)$ and $f_X(x)$, respectively. We assume that $f_X(x) > 0$ on the support of X ; so, in particular, $F_X(x)$ is strictly increasing on the support. In this and the succeeding chapters, we want to identify classes of parameters. Think of a parameter as a function of the cdf (or pdf) of a given random variable. For example, consider the mean μ of X . We can write it as $\mu_X = T(F_X)$ if T is defined as

$$T(F_X) = E(X).$$

As another example, recall that the median of a random variable X is a parameter ξ such that $F_X(\xi) = 1/2$; i.e., $\xi = F_X^{-1}(1/2)$. Hence, in this notation, we say that the parameter ξ is defined by the function $T(F_X) = F_X^{-1}(1/2)$. Note that these T s are functions of the cdfs (or pdfs). We shall call them **functionals**.

Remark 10.1.1 (Natural Nonparametric Estimators). Functionals induce nonparametric estimators naturally. Let X_1, X_2, \dots, X_n denote a random sample from some distribution with cdf $F(x)$ and let $T(F)$ be a functional. Let x_1, x_2, \dots, x_n be a realization of this sample. Recall that the empirical distribution function of the sample is given by

$$\hat{F}_n(x) = n^{-1}[\#\{x_i \leq x\}], \quad -\infty < x < \infty. \quad (10.1.1)$$

Hence, F_n is a discrete cdf that puts mass (probability) $1/n$ at each x_i . Because $\hat{F}_n(x)$ is a cdf, $T(\hat{F}_n)$ is well defined. Furthermore, $T(\hat{F}_n)$ depends only on the sample; hence, it is a statistic. We call $T(\hat{F}_n)$ the **induced estimator** of $T(F)$. For example, if $T(F)$ is the mean of the distribution, then it is easy to see that $T(\hat{F}_n) = \bar{x}$; see Exercise 10.1.3.

For another example, consider the median. Note that \hat{F}_n is a discrete cdf; hence, we use the general definition of a median of a distribution that is given in Definition 1.7.2 of Chapter 1. Let $\hat{\theta}$ denote the usual sample median which is defined in expression (4.4.4); that is, $\hat{\theta} = x_{((n+1)/2)}$ if n is odd while $\hat{\theta} = [x_{(n/2)} + x_{((n/2)+1)}]/2$ if n is even. To show that $\hat{\theta}$ satisfies Definition 1.7.2, note that:

- If n is even, then $\hat{F}_n(\hat{\theta}) = 1/2$.
- If n is odd then

$$n^{-1}\#\{x_i < \hat{\theta}\} = \frac{1}{2} - \frac{1}{n} \leq 1/2 \text{ and } F_n(\hat{\theta}) \geq 1/2.$$

Thus in either case, by Definition 1.7.2, $\hat{\theta}$ is a median of \hat{F}_n . Note that when n is even any point in the interval $(X_{(n/2)}, X_{((n/2)+1)})$ satisfies the definition of a median. ■

We begin with the definition of a location functional.

Definition 10.1.1. Let X be a continuous random variable with cdf $F_X(x)$ and pdf $f_X(x)$. We say that $T(F_X)$ is a **location functional** if it satisfies

$$\text{If } Y = X + a, \text{ then } T(F_Y) = T(F_X) + a, \text{ for all } a \in R, \quad (10.1.2)$$

$$\text{If } Y = aX; \text{ then } T(F_Y) = aT(F_X), \text{ for all } a \neq 0. \quad (10.1.3)$$

For example, suppose T is the mean functional; i.e., $T(F_X) = E(X)$. Let $Y = X + a$; then $E(Y) = E(X + a) = E(X) + a$. Secondly, if $Y = aX$, then $E(Y) = aE(X)$. Hence the mean is a location functional. The next example shows that the median is a location functional.

Example 10.1.1. Let $F(x)$ be the cdf of X and let $T(F_X) = F_X^{-1}(1/2)$ be the median functional of X . Note that another way to state this is $F_X(T(F_X)) = 1/2$. Let $Y = X + a$. It then follows that the cdf of Y is $F_Y(y) = F_X(y - a)$. The following identity shows that $T(F_Y) = T(F_X) + a$:

$$F_Y(T(F_X) + a) = F_X(T(F_X) + a - a) = F_X(T(F_X)) = 1/2.$$

Next, suppose $Y = aX$. If $a > 0$, then $F_Y(y) = F_X(y/a)$ and, hence,

$$F_Y(aT(F_X)) = F_X(aT(F_X)/a) = F_X(T(F_X)) = 1/2.$$

Thus $T(F_Y) = aT(F_X)$ when $a > 0$. On the other hand, if $a < 0$, then $F_Y(y) = 1 - F_X(y/a)$. Hence

$$F_Y(aT(F_X)) = 1 - F_X(aT(F_X)/a) = 1 - F_X(T(F_X)) = 1 - \frac{1}{2} = \frac{1}{2}.$$

Therefore, (10.1.3) holds for all $a \neq 0$. Thus the median is a location functional.

Recall that the median is a percentile, namely, the 50th percentile of a distribution. As Exercise 10.1.1 shows, the median is the only percentile that is a location functional. ■

We often continue to use parameter notation to denote functionals. For example, $\theta_X = T(F_X)$.

In Chapters 4 and 6, we wrote the location model for specified pdfs. In this chapter, we write it for a general pdf in terms of a specified location functional. Let X be a random variable with cdf $F_X(x)$ and pdf $f_X(x)$. Let $\theta_X = T(F_X)$ be a location functional. Define the random variable ε to be $\varepsilon = X - T(F_X)$. Then by (10.1.2), $T(F_\varepsilon) = 0$; i.e., ε has location 0, according to T . Further, the pdf of X can be written as $f_X(x) = f(x - T(F_X))$, where $f(x)$ is the pdf of ε .

Definition 10.1.2 (Location Model). *Let $\theta_X = T(F_X)$ be a location functional. We say that the observations X_1, X_2, \dots, X_n follow a **location model** with functional $\theta_X = T(F_X)$ if*

$$X_i = \theta_X + \varepsilon_i, \quad (10.1.4)$$

where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid random variables with pdf $f(x)$ and $T(F_\varepsilon) = 0$. Hence, from the above discussion, X_1, X_2, \dots, X_n are iid with pdf $f_X(x) = f(x - T(F_X))$.

Example 10.1.2. Let ε be a random variable with cdf $F(x)$, such that $F(0) = 1/2$. Assume that $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid with cdf $F(x)$. Let $\theta \in R$ and define

$$X_i = \theta + \varepsilon_i, \quad i = 1, 2, \dots, n.$$

Then X_1, X_2, \dots, X_n follow the location model with the locational functional θ , which is the median of X_i . ■

Note that the location model very much depends on the functional. It forces one to state clearly which location functional is being used in order to write the model statement. For the class of symmetric densities, though, all location functionals are the same.

Theorem 10.1.1. *Let X be a random variable with cdf $F_X(x)$ and pdf $f_X(x)$ such that the distribution of X is symmetric about a . Let $T(F_X)$ be any location functional. Then $T(F_X) = a$.*

Proof: By (10.1.2), we have

$$T(F_{X-a}) = T(F_X) - a. \quad (10.1.5)$$

Since the distribution of X is symmetric about a , it is easy to show that $X - a$ and $-(X - a)$ have the same distribution; see Exercise 10.1.2. Hence, using (10.1.2) and (10.1.3), we have

$$T(F_{X-a}) = T(F_{-(X-a)}) = -(T(F_X) - a) = -T(F_X) + a. \quad (10.1.6)$$

Putting (10.1.5) and (10.1.6) together gives the result. ■

The assumption of symmetry is very appealing, because the concept of “center” is unique when it is true.

EXERCISES

10.1.1. Let X be a continuous random variable with cdf $F(x)$. For $0 < p < 1$, let ξ_p be the p th quantile; i.e., $F(\xi_p) = p$. If $p \neq 1/2$, show that while property (10.1.2) holds, property (10.1.3) does not. Thus ξ_p is not a location parameter.

10.1.2. Let X be a continuous random variable with pdf $f(x)$. Suppose $f(x)$ is symmetric about a ; i.e., $f(x - a) = f(-(x - a))$. Show that the random variables $X - a$ and $-(X - a)$ have the same pdf.

10.1.3. Let $\widehat{F}_n(x)$ denote the empirical cdf of the sample X_1, X_2, \dots, X_n . The distribution of $\widehat{F}_n(x)$ puts mass $1/n$ at each sample item X_i . Show that its mean is \bar{X} . If $T(F) = F^{-1}(1/2)$ is the median, show that $T(\widehat{F}_n) = Q_2$, the sample median.

10.1.4. Let X be a random variable with cdf $F(x)$ and let $T(F)$ be a functional. We say that $T(F)$ is a **scale functional** if it satisfies the three properties

- (i) $T(F_{aX}) = aT(F_X)$, for $a > 0$
- (ii) $T(F_{X+b}) = T(F_X)$, for all b
- (iii) $T(F_{-X}) = T(F_X)$.

Show that the following functionals are scale functionals.

(a) The standard deviation, $T(F_X) = (\text{Var}(X))^{1/2}$.

(b) The interquartile range, $T(F_X) = F_X^{-1}(3/4) - F_X^{-1}(1/4)$.

10.2 Sample Median and the Sign Test

In this section, we consider inference for the median of a distribution using the sample median. Fundamental to this discussion is the sign test statistic, which we present first.

Let X_1, X_2, \dots, X_n be a random sample that follows the location model

$$X_i = \theta + \varepsilon_i, \quad (10.2.1)$$

where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid with cdf $F(x)$, pdf $f(x)$, and median 0. Note that in terms of Section 10.1, the location functional is the median and, hence, θ is the median of X_i . We begin with a test for the one-sided hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta > \theta_0. \quad (10.2.2)$$

Consider the statistic

$$S(\theta_0) = \#\{X_i > \theta_0\}, \quad (10.2.3)$$

which is called the **sign statistic** because it counts the number of positive signs in the differences $X_i - \theta_0$, $i = 1, 2, \dots, n$. If we define $I(x > a)$ to be 1 or 0 depending on whether $x > a$ or $x \leq a$, then we can express $S(\theta_0)$ as

$$S(\theta_0) = \sum_{i=1}^n I(X_i > \theta_0). \quad (10.2.4)$$

Note that if H_0 is true, then we expect one half of the observations to exceed θ_0 , while if H_1 is true, we expect more than half of the observations to exceed θ_0 . Consider then the test of the hypotheses (10.2.2) given by

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } S(\theta_0) \geq c. \quad (10.2.5)$$

Under the null hypothesis, the random variables $I(X_i > \theta_0)$ are iid with a Bernoulli $b(1, 1/2)$ distribution. Hence the null distribution of $S(\theta_0)$ is $b(n, 1/2)$ with mean $n/2$ and variance $n/4$. Note that under H_0 , the sign test does not depend on the distribution of X_i . In general, we call such a test a **distribution free** test.

For a level α test, select c to be c_α , where c_α is the upper α critical point of a binomial $b(n, 1/2)$ distribution. The test statistic, though, has a discrete distribution, so for an exact test there are only a finite number of levels α available. The values of c_α are easily found by most computer packages. For instance, the R command `pbinom(0:15, 15, .5)` returns the cdf of a binomial distribution with $n = 15$ and $p = 0.5$, from which all possible levels can be seen.

For a given data set, the p -value associated with the sign test is given by $\hat{p} = P_{H_0}(S(\theta_0) \geq s)$, where s is the realized value of $S(\theta_0)$ based on the sample. For computation, the R command `1 - pbinom(s-1, n, .5)` computes \hat{p} .

It is convenient at times to use a large sample test based on the asymptotic distribution of the test statistic. By the Central Limit Theorem, under H_0 the standardized statistic $[S(\theta_0) - (n/2)]/\sqrt{n}/2$ is asymptotically normal, $N(0, 1)$. Hence the large sample test rejects H_0 if

$$\frac{S(\theta_0) - (n/2)}{\sqrt{n}/2} \geq z_\alpha; \quad (10.2.6)$$

see Exercise 10.2.2.

We briefly touch on the two-sided hypotheses given by

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta \neq \theta_0. \quad (10.2.7)$$

The following symmetric decision rule seems appropriate:

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } S(\theta_0) \leq c_1 \text{ or if } S(\theta_0) \geq n - c_1. \quad (10.2.8)$$

For a level α test, c_1 would be chosen such that $\alpha/2 = P_{H_0}(S(\theta_0) \leq c_1)$. Recall that the p -value is given by $\hat{p} = 2 \min\{P_{H_0}(S(\theta_0) \leq s), P_{H_0}(S(\theta_0) \geq s)\}$, where s is the realized value of $S(\theta_0)$ based on the sample.

Example 10.2.1 (Shoshoni Rectangles). A golden rectangle is a rectangle in which the ratio of the width (w) to the length (l) is the golden ratio, which is approximately 0.618. It can be characterized in various ways. For example, $w/l = l/(w+l)$ characterizes the golden rectangle. It is considered to be an aesthetic standard in Western civilization and appears in art and architecture going back to the ancient Greeks. It now appears in such items as credit and business cards. In a cultural anthropology study, DuBois (1960) reports on a study of the Shoshoni beaded baskets. These baskets contain beaded rectangles, and the question was whether the Shoshonis use the same aesthetic standard as the West. Let X denote the ratio of the width to the length of a Shoshoni beaded basket. Let θ be the median of X . The hypotheses of interest are

$$H_0 : \theta = 0.618 \text{ versus } H_1 : \theta \neq 0.618.$$

These are two-sided hypotheses. It follows from the above discussion that the sign test rejects H_0 in favor of H_1 if $S(0.618) \leq c$ or $S(0.618) \geq n - c$.

A sample of 20 width to length (ordered) ratios from Shoshoni baskets resulted in the data

Width-to-Length Ratios of Rectangles										
0.553	0.570	0.576	0.601	0.606	0.606	0.609	0.611	0.615	0.628	
0.654	0.662	0.668	0.670	0.672	0.690	0.693	0.749	0.844	0.933	

The data can be found in the file `shoshoni.rda`. For these data, the sign test statistic is $S(0.618) = 11$. Using R the p -value is: $2*(1-pbinom(10, 20, .5)) = 0.8238$. Thus there is no evidence to reject H_0 based on these data.

A boxplot and a normal $q-q$ plot of the data are given in Figure 10.2.1. Notice that the data contain two, possibly three, potential outliers. The data do not appear to be drawn from a normal distribution. ■

We next obtain several useful results concerning the power function of the sign test for the hypotheses (10.2.2). The following function proves useful here and in the associated estimation and confidence intervals described below. Define

$$S(\theta) = \#\{X_i > \theta\}. \quad (10.2.9)$$

The sign test statistic is given by $S(\theta_0)$. We can easily describe the function $S(\theta)$. First, note that we can write it in terms of the order statistics $Y_1 < \dots < Y_n$ of X_1, \dots, X_n because $\#\{Y_i > \theta\} = \#\{X_i > \theta\}$. Now if $\theta < Y_1$, then all the Y_i s are larger than θ and, hence $S(\theta) = n$. Next, if $Y_1 \leq \theta < Y_2$ then $S(\theta) = n - 1$. Continuing this way, we see that $S(\theta)$ is a decreasing step function of θ , which steps

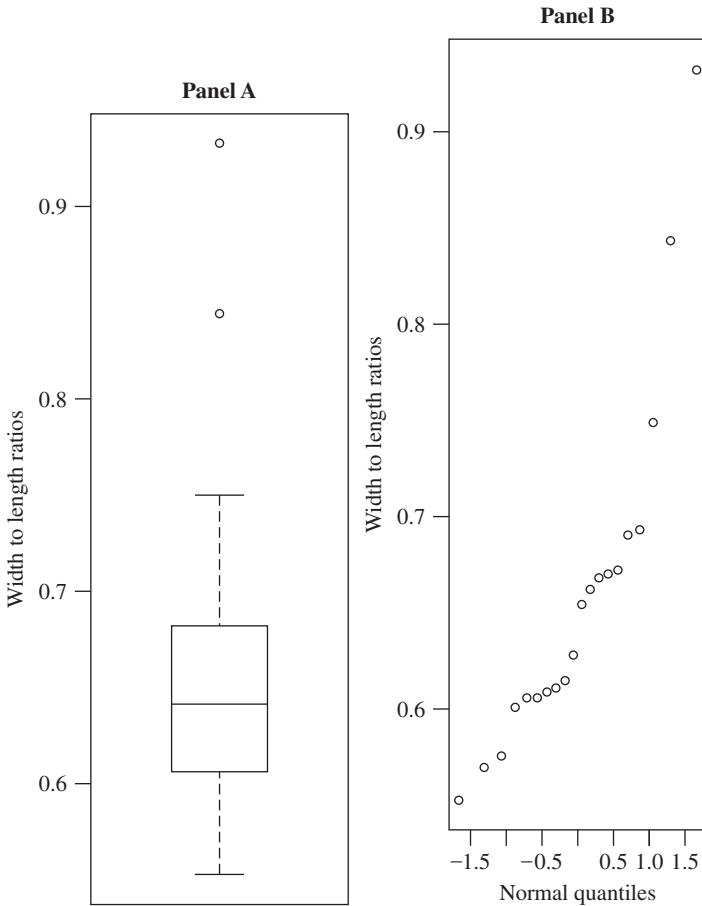

Figure 10.2.1: Boxplot (Panel A) and normal $q-q$ plot (Panel B) of the Shoshoni data.

down one unit at each order statistic Y_i , attaining its maximum and minimum values n and 0 at Y_1 and Y_n , respectively. Figure 10.2.2 depicts this function.

We need the following translation property. Because we can always subtract θ_0 from each X_i , we can assume without loss of generality that $\theta_0 = 0$.

Lemma 10.2.1. *For every k ,*

$$P_\theta[S(0) \geq k] = P_0[S(-\theta) \geq k]. \quad (10.2.10)$$

Proof: Note that the left side of equation (10.2.10) concerns the probability of the event $\#\{X_i > 0\}$, where X_i has median θ . The right side concerns the probability of the event $\#\{(X_i + \theta) > 0\}$, where the random variable $X_i + \theta$ has median θ (because under $\theta = 0$, X_i has median 0). Hence the left and right sides give the same probability. ■

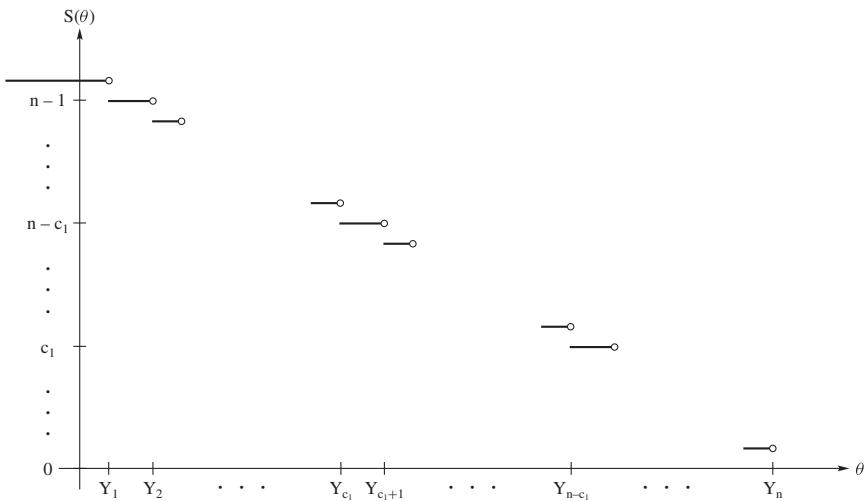

Figure 10.2.2: The sketch shows the graph of the decreasing step function $S(\theta)$. The function drops one unit at each order statistic Y_i .

Based on this lemma, it is easy to show that the power function of the sign test is monotone for one-sided tests.

Theorem 10.2.1. Suppose Model (10.2.1) is true. Let $\gamma(\theta)$ be the power function of the sign test of level α for the one-sided hypotheses (10.2.2). Then $\gamma(\theta)$ is a nondecreasing function of θ .

Proof: Let c_α denote the $b(n, 1/2)$ upper critical value as defined after expression (10.2.8). Without loss of generality, assume that $\theta_0 = 0$. The power function of the sign test is

$$\gamma(\theta) = P_\theta[S(0) \geq c_\alpha], \quad \text{for } -\infty < \theta < \infty.$$

Suppose $\theta_1 < \theta_2$. Then $-\theta_1 > -\theta_2$ and hence, since $S(\theta)$ is nonincreasing, $S(-\theta_1) \leq S(-\theta_2)$. This and Lemma 10.2.1 yield the desired result; i.e.,

$$\begin{aligned} \gamma(\theta_1) &= P_{\theta_1}[S(0) \geq c_\alpha] \\ &= P_0[S(-\theta_1) \geq c_\alpha] \\ &\leq P_0[S(-\theta_2) \geq c_\alpha] \\ &= P_{\theta_2}[S(0) \geq c_\alpha] \\ &= \gamma(\theta_2). \blacksquare \end{aligned}$$

This is a very desirable property for any test. Because the monotonicity of the power function of the sign test holds for all θ , $-\infty < \theta < \infty$, we can extend the simple null hypothesis of (10.2.2) to the composite null hypothesis

$$H_0 : \theta \leq \theta_0 \text{ versus } H_1 : \theta > \theta_0. \tag{10.2.11}$$

Recall from Definition 4.5.4 of Chapter 4 that the size of the test for a composite null hypothesis is given by $\max_{\theta \leq \theta_0} \gamma(\theta)$. Because $\gamma(\theta)$ is nondecreasing, the size of the sign test is α for this extended null hypothesis. As a second result, it follows immediately that the sign test is an unbiased test; see Section 8.3. As Exercise 10.2.8 shows, the power function of the sign test for the other one-sided alternative, $H_1 : \theta < \theta_0$, is nonincreasing.

Under an alternative, say $\theta = \theta_1$, the test statistic $S(\theta_0)$ has the binomial distribution $b(n, p_1)$, where p_1 is given by

$$p_1 = P_{\theta_1}(X > 0) = 1 - F(-\theta_1), \quad (10.2.12)$$

where $F(x)$ is the cdf of ε in Model (10.2.1). Hence $S(\theta_0)$ is not distribution free under alternative hypotheses. As in Exercise 10.2.3, we can determine the power of the test for specified θ_1 and $F(x)$. We want to compare the power of the sign test to other size α tests, in particular the test based on the sample mean. However, for these comparison purposes, we need more general results, some of which are obtained in the next subsection.

10.2.1 Asymptotic Relative Efficiency

One solution to this problem is to consider the behavior of a test under a sequence of local alternatives. In this section, we often take $\theta_0 = 0$ in hypotheses (10.2.2). As noted before Lemma 10.2.1, this is without loss of generality. For the hypotheses (10.2.2), consider the sequence of alternatives

$$H_0 : \theta = 0 \text{ versus } H_{1n} : \theta_n = \frac{\delta}{\sqrt{n}}, \quad (10.2.13)$$

where $\delta > 0$. Note that this sequence of alternatives converges to the null hypothesis as $n \rightarrow \infty$. We often call such a sequence of alternatives **local alternatives**. The idea is to consider how the power function of a test behaves relative to the power functions of other tests under this sequence of alternatives. We only sketch this development. For more details, the reader can consult the more advanced books cited in Section 10.1. As a first step in that direction, we obtain the asymptotic power lemma for the sign test.

Consider the large sample size α test given by (10.2.6). Under the alternative

θ_n , we can approximate the mean of this test as follows:

$$\begin{aligned}
 E_{\theta_n} \left[\frac{1}{\sqrt{n}} \left(S(0) - \frac{n}{2} \right) \right] &= E_0 \left[\frac{1}{\sqrt{n}} \left(S(-\theta_n) - \frac{n}{2} \right) \right] \\
 &= \frac{1}{\sqrt{n}} \sum_{i=1}^n E_0[I(X_i > -\theta_n)] - \frac{\sqrt{n}}{2} \\
 &= \frac{1}{\sqrt{n}} \sum_{i=1}^n P_0(X_i > -\theta_n) - \frac{\sqrt{n}}{2} \\
 &= \sqrt{n} \left(1 - F(-\theta_n) - \frac{1}{2} \right) \\
 &= \sqrt{n} \left(\frac{1}{2} - F(-\theta_n) \right) \\
 &\approx \sqrt{n} \theta_n f(0) = \delta f(0), \tag{10.2.14}
 \end{aligned}$$

where the step to the last line is due to the mean value theorem. It can be shown in more advanced texts that the variance of $[S(0) - (n/2)]/(\sqrt{n}/2)$ converges to 1 under θ_n , just as under H_0 , and that, furthermore, $[S(0) - (n/2) - \sqrt{n}\delta f(0)]/(\sqrt{n}/2)$ has a limiting standard normal distribution. This leads to the **asymptotic power lemma**, which we state in the form of a theorem.

Theorem 10.2.2 (Asymptotic Power Lemma). *Consider the sequence of hypotheses (10.2.13). The limit of the power function of the large sample, size α , sign test is*

$$\lim_{n \rightarrow \infty} \gamma(\theta_n) = 1 - \Phi(z_\alpha - \delta \tau_S^{-1}), \tag{10.2.15}$$

where $\tau_S = 1/[2f(0)]$ and $\Phi(z)$ is the cdf of a standard normal random variable.

Proof: Using expression (10.2.14) and the discussion that followed its derivation, we have

$$\begin{aligned}
 \gamma(\theta_n) &= P_{\theta_n} \left[\frac{n^{-1/2}[S(0) - (n/2)]}{1/2} \geq z_\alpha \right] \\
 &= P_{\theta_n} \left[\frac{n^{-1/2}[S(0) - (n/2) - \sqrt{n}\delta f(0)]}{1/2} \geq z_\alpha - \delta 2f(0) \right] \\
 &\rightarrow 1 - \Phi(z_\alpha - \delta 2f(0)),
 \end{aligned}$$

which was to be shown. ■

As shown in Exercise 10.2.5, the parameter $\tau_S = 1/[2f(0)]$ is a scale parameter (functional) as defined in Exercise 10.1.4 of the last section. We later show that τ_S/\sqrt{n} is the asymptotic standard deviation of the sample median.

Note that there were several approximations used in the proof of Theorem 10.2.2. A rigorous proof can be found in more advanced texts, such as those cited in Section 10.1. It is quite helpful for the next sections to reconsider the approximation of the

mean given in (10.2.14) in terms of another concept called **efficacy**. Consider another standardization of the test statistic given by

$$\bar{S}(0) = \frac{1}{n} \sum_{i=1}^n I(X_i > 0), \quad (10.2.16)$$

where the bar notation is used to signify that $\bar{S}(0)$ is an average of $I(X_i > 0)$ and, in this case under H_0 , converges in probability to $\frac{1}{2}$. Let $\mu(\theta) = E_\theta(\bar{S}(0) - \frac{1}{2})$. Then, by expression (10.2.14), we have

$$\mu(\theta_n) = E_{\theta_n} \left(\bar{S}(0) - \frac{1}{2} \right) = \frac{1}{2} - F(-\theta_n). \quad (10.2.17)$$

Let $\sigma_S^2 = \text{Var}(\bar{S}(0)) = \frac{1}{4n}$. Finally, define the **efficacy** of the sign test to be

$$c_S = \lim_{n \rightarrow \infty} \frac{\mu'(0)}{\sqrt{n}\sigma_S}. \quad (10.2.18)$$

That is, the efficacy is the rate of change of the mean of the test statistic at the null divided by the product of \sqrt{n} and the standard deviation of the test statistic at the null. So the efficacy increases with an increase in this rate, as it should. We use this formulation of efficacy throughout this chapter.

Hence, by expression (10.2.14), the efficacy of the sign test is

$$c_S = \frac{f(0)}{1/2} = 2f(0) = \tau_S^{-1}, \quad (10.2.19)$$

the reciprocal of the scale parameter τ_S . In terms of efficacy, we can write the conclusion of the Asymptotic Power Lemma as

$$\lim_{n \rightarrow \infty} \gamma(\theta_n) = 1 - \Phi(z_\alpha - \delta c_S). \quad (10.2.20)$$

This is not a coincidence, and it is true for the procedures we consider in the next section.

Remark 10.2.1. In this chapter, we compare nonparametric procedures with traditional parametric procedures. For instance, we compare the sign test with the test based on the sample mean. Traditionally, tests based on sample means are referred to as *t*-tests. Even though our comparisons are asymptotic and we could use the terminology of *z*-tests, we instead use the traditional terminology of *t*-tests. ■

As a second illustration of efficacy, we determine the efficacy of the *t*-test for the mean. Assume that the random variables ε_i in Model (10.2.1) are symmetrically distributed about 0 and their mean exists. Hence the parameter θ is the location parameter. In particular, $\theta = E(X_i) = \text{med}(X_i)$. Denote the variance of X_i by σ^2 . This allows us to easily compare the sign and *t*-tests. Recall for hypotheses (10.2.2) that the *t*-test rejects H_0 in favor of H_1 if $\bar{X} \geq c$. The form of the test statistic is then \bar{X} . Furthermore, we have

$$\mu_{\bar{X}}(\theta) = E_\theta(\bar{X}) = \theta \quad (10.2.21)$$

and

$$\sigma_{\bar{X}}^2(0) = V_0(\bar{X}) = \frac{\sigma^2}{n}. \quad (10.2.22)$$

Thus, by (10.2.21) and (10.2.22), the efficacy of the t -test is

$$c_t = \lim_{n \rightarrow \infty} \frac{\mu'_{\bar{X}}(0)}{\sqrt{n}(\sigma/\sqrt{n})} = \frac{1}{\sigma}. \quad (10.2.23)$$

As confirmed in Exercise 10.2.9, the asymptotic power of the large sample level α , t -test under the sequence of alternatives (10.2.13) is $1 - \Phi(z_\alpha - \delta c_t)$. Thus we can compare the sign and t -tests by comparing their efficacies. We do this from the perspective of sample size determination.

Assume without loss of generality that $H_0 : \theta = 0$. Now suppose we want to determine the sample size so that a level α sign test can detect the alternative $\theta^* > 0$ with (approximate) probability γ^* . That is, find n so that

$$\gamma^* = \gamma(\theta^*) = P_{\theta^*} \left[\frac{S(0) - (n/2)}{\sqrt{n}/2} \geq z_\alpha \right]. \quad (10.2.24)$$

Write $\theta^* = \sqrt{n}\theta^*/\sqrt{n}$. Then, using the asymptotic power lemma, we have

$$\gamma^* = \gamma(\sqrt{n}\theta^*/\sqrt{n}) \approx 1 - \Phi(z_\alpha - \sqrt{n}\theta^*\tau_S^{-1}).$$

Now denote z_{γ^*} to be the upper $1 - \gamma^*$ quantile of the standard normal distribution. Then, from this last equation, we have

$$z_{\gamma^*} = z_\alpha - \sqrt{n}\theta^*\tau_S^{-1}.$$

Solving for n , we get

$$n_S = \left(\frac{(z_\alpha - z_{\gamma^*})\tau_S}{\theta^*} \right)^2. \quad (10.2.25)$$

As outlined in Exercise 10.2.9, for this situation the sample size determination for the test based on the sample mean is

$$n_{\bar{X}} = \left(\frac{(z_\alpha - z_{\gamma^*})\sigma}{\theta^*} \right)^2, \quad (10.2.26)$$

where $\sigma^2 = \text{Var}(\varepsilon)$.

Suppose we have two tests of the same level for which the asymptotic power lemma holds and for each we determine the sample size necessary to achieve power γ^* at the alternative θ^* . Then the ratio of these sample sizes is called the **asymptotic relative efficiency** (ARE) between the tests. We show later that this is the same as the ARE defined in Chapter 6 between estimators. Hence the ARE of the sign test to the t -test is

$$\text{ARE}(S, t) = \frac{n_{\bar{X}}}{n_S} = \frac{\sigma^2}{\tau_S^2} = \frac{c_S^2}{c_t^2}. \quad (10.2.27)$$

Note that this is the same relative efficiency that was discussed in Example 6.2.5 when the sample median was compared to the sample mean. In the next two examples we revisit this discussion by examining the AREs when X_i has a normal distribution and then a Laplace (double exponential) distribution.

Example 10.2.2 (ARE(S, t): normal distribution). Suppose X_1, X_2, \dots, X_n follow the location model (10.1.4), where $f(x)$ is a $N(0, \sigma^2)$ pdf. Then $\tau_S = (2f(0))^{-1} = \sigma\sqrt{\pi/2}$. Hence the ARE(S, t) is given by

$$\text{ARE}(S, t) = \frac{\sigma^2}{\tau_S^2} = \frac{\sigma^2}{(\pi/2)\sigma^2} = \frac{2}{\pi} \approx 0.637. \quad (10.2.28)$$

Hence at the normal distribution the sign test is only 64% as efficient as the t -test. In terms of sample size at the normal distribution, the t -test requires a smaller sample, $0.64n_s$, where n_s is the sample size of the sign test, to achieve the same power as the sign test. A cautionary note is needed here because this is asymptotic efficiency. There have been ample empirical (simulation) studies that give credence to these numbers. ■

Example 10.2.3 (ARE(S, t) at the Laplace distribution). For this example, consider Model (10.1.4), where $f(x)$ is the Laplace pdf $f(x) = (2b)^{-1} \exp\{-|x|/b\}$ for $-\infty < x < \infty$ and $b > 0$. Then $\tau_S = (2f(0))^{-1} = b$, while $\sigma^2 = E(X^2) = 2b^2$. Hence the ARE(S, t) is given by

$$\text{ARE}(S, t) = \frac{\sigma^2}{\tau_S^2} = \frac{2b^2}{b^2} = 2. \quad (10.2.29)$$

So, at the Laplace distribution, the sign test is (asymptotically) twice as efficient as the t -test. In terms of sample size at the Laplace distribution, the t -test requires twice as large a sample as the sign test to achieve the same asymptotic power as the sign test.

Recall from Example 6.3.4 that the sign test is the scores type likelihood ratio test when the true distribution is the Laplace. ■

The normal distribution has much lighter tails than the Laplace distribution, because the two pdfs are proportional to $\exp\{-t^2/2\sigma^2\}$ and $\exp\{-|t|/b\}$, respectively. Based on the last two examples, it seems that the t -test is more efficient for light-tailed distributions while the sign test is more efficient for heavier-tailed distributions. This is true in general and we illustrate this in the next example where we can easily vary the tail weight from light to heavy.

Example 10.2.4 (ARE(S, t) at a family of contaminated normals). Consider the location Model (10.1.4), where the cdf of ε_i is the contaminated normal cdf given in expression (3.4.19). Assume that $\theta_0 = 0$. Recall that for this distribution, $(1 - \epsilon)$ proportion of the time the sample is drawn from a $N(0, b^2)$ distribution, while ϵ proportion of the time the sample is drawn from a $N(0, b^2\sigma_c^2)$ distribution. The corresponding pdf is given by

$$f(x) = \frac{1 - \epsilon}{b} \phi\left(\frac{x}{b}\right) + \frac{\epsilon}{b\sigma_c} \phi\left(\frac{x}{b\sigma_c}\right), \quad (10.2.30)$$

where $\phi(z)$ is the pdf of a standard normal random variable. As shown in Section 3.4, the variance of ε_i is $b^2(1 + \epsilon(\sigma_c^2 - 1))$. Also, $\tau_s = (b\sqrt{\pi/2})/[1 - \epsilon + (\epsilon/\sigma_c)]$. Thus the ARE is

$$\text{ARE}(S, t) = \frac{2}{\pi}[(1 + \epsilon(\sigma_c^2 - 1))[1 - \epsilon + (\epsilon/\sigma_c)]^2]. \quad (10.2.31)$$

For example, the following table (see Exercise 6.2.6) shows the AREs for various values of ϵ when σ_c is set at 3.0:

ϵ	0	0.01	0.02	0.03	0.05	0.10	0.15	0.25
ARE(S,t)	0.636	0.678	0.718	0.758	0.832	0.998	1.134	1.326

Note: if ϵ increases over the range of values in the table, then the contamination effect becomes larger (generally resulting in a heavier-tailed distribution) and as the table shows, the sign test becomes more efficient relative to the t -test. Increasing σ_c has the same effect. It does take, however, with $\sigma_c = 3$, over 10% contamination before the sign test becomes more efficient than the t -test. ■

10.2.2 Estimating Equations Based on the Sign Test

In practice, we often want to estimate θ , the median of X_i , in Model (10.2.1). The associated point estimate based on the sign test can be described with a simple geometry, which is analogous to the geometry of the sample mean. As Exercise 10.2.6 shows, the sample mean \bar{X} is such that

$$\bar{X} = \text{Argmin} \sqrt{\sum_{i=1}^n (X_i - \theta)^2}. \quad (10.2.32)$$

The quantity $\sqrt{\sum_{i=1}^n (X_i - \theta)^2}$ is the Euclidean distance between the vector of observations $\mathbf{X} = (X_1, X_2, \dots, X_n)'$ and the vector $\theta\mathbf{1}$. If we simply interchange the square root and the summation symbols, we go from the Euclidean distance to the L_1 distance. Let

$$\hat{\theta} = \text{Argmin} \sum_{i=1}^n |X_i - \theta|. \quad (10.2.33)$$

To determine $\hat{\theta}$, simply differentiate the quantity on the right side with respect to θ (as in Chapter 6, define the derivative of $|x|$ to be 0 at $x = 0$). We then obtain

$$\frac{\partial}{\partial \theta} \sum_{i=1}^n |X_i - \theta| = - \sum_{i=1}^n \text{sgn}(X_i - \theta).$$

Setting this to 0, we obtain the estimating equations (EE)

$$\sum_{i=1}^n \text{sgn}(X_i - \theta) = 0, \quad (10.2.34)$$

whose solution is the sample median Q_2 , (4.4.4).

Because our observations are continuous random variables, we have the identity

$$\sum_{i=1}^n \text{sgn}(X_i - \theta) = 2S(\theta) - n.$$

Hence the sample median also solves $S(\theta) \approx n/2$. Consider again Figure 10.2.2. Imagine $n/2$ on the vertical axis. This is halfway in the total drop of $S(\theta)$, from n to 0. The order statistic on the horizontal axis corresponding to $n/2$ is essentially the sample median (middle order statistic). In terms of testing, this last equation says that, based on the data, the sample median is the “most acceptable” hypothesis, because $n/2$ is the null expected value of the test statistic. We often think of this as estimation by the inversion of a test.

We now sketch the asymptotic distribution of the sample median. Assume without loss of generality that the true median of X_i is 0. Suppose $-\infty < x < \infty$. Using the fact that $S(\theta)$ is nonincreasing and the identity $S(\theta) \approx n/2$, we have the following equivalences:

$$\{\sqrt{n}Q_2 \leq x\} \Leftrightarrow \left\{ Q_2 \leq \frac{x}{\sqrt{n}} \right\} \Leftrightarrow \left\{ S\left(\frac{x}{\sqrt{n}}\right) \leq \frac{n}{2} \right\}.$$

Hence we have

$$\begin{aligned} P_0(\sqrt{n}Q_2 \leq x) &= P_0\left[S\left(\frac{x}{\sqrt{n}}\right) \leq \frac{n}{2}\right] \\ &= P_{-x/\sqrt{n}}\left[S(0) \leq \frac{n}{2}\right] \\ &= P_{-x/\sqrt{n}}\left[\frac{S(0) - (n/2)}{\sqrt{n}/2} \leq 0\right] \\ &\rightarrow \Phi(0 - x\tau_S^{-1}) = P(\tau_S Z \leq x), \end{aligned}$$

where Z has a standard normal distribution. Notice that the limit was obtained by invoking the Asymptotic Power Lemma with $\alpha = 0.5$ and hence $z_\alpha = 0$. Rearranging the last term earlier, we obtain the asymptotic distribution of the sample median, which we state as a theorem:

Theorem 10.2.3. *For the random sample X_1, X_2, \dots, X_n , assume that Model (10.2.1) holds. Suppose that $f(0) > 0$. Let Q_2 denote the sample median. Then*

$$\sqrt{n}(Q_2 - \theta) \rightarrow N(0, \tau_S^2), \quad (10.2.35)$$

where $\tau_S = (2f(0))^{-1}$.

In Section 6.2 we defined the ARE between two estimators to be the reciprocal of their asymptotic variances. For the sample median and mean, this is the same ratio as that based on sample size determinations of their respective tests given earlier in expression (10.2.27).

10.2.3 Confidence Interval for the Median

In Section 4.4, we obtained a confidence interval for the median. In this section, we derive this confidence interval by inverting the sign test. Based on the monotonicity of $S(\theta)$, the derivation is straightforward, but the technique will prove useful in subsequent sections of this chapter.

Suppose the random sample X_1, X_2, \dots, X_n follows the location model (10.2.1). In this subsection, we develop a confidence interval for the median θ of X_i . Assuming that θ is the true median, the random variable $S(\theta)$, (10.2.9), has a binomial $b(n, 1/2)$ distribution. For $0 < \alpha < 1$, select c_1 so that $P_\theta[S(\theta) \leq c_1] = \alpha/2$. Hence we have

$$1 - \alpha = P_\theta[c_1 < S(\theta) < n - c_1]. \quad (10.2.36)$$

Recall in our derivation for the t -confidence interval for the mean in Chapter 3, we began with such a statement and then “inverted” the pivot random variable $t = \sqrt{n}(\bar{X} - \mu)/S$ (S in this expression is the sample standard deviation) to obtain an equivalent inequality with μ isolated in the middle. In this case, the function $S(\theta)$ does not have an inverse, but it is a decreasing step function of θ and the inversion can still be performed. As depicted in Figure 10.2.2, $c_1 < S(\theta) < n - c_1$ if and only if $Y_{c_1+1} \leq \theta < Y_{n-c_1}$, where $Y_1 < Y_2 < \dots < Y_n$ are the order statistics of the sample X_1, X_2, \dots, X_n . Therefore, the interval $[Y_{c_1+1}, Y_{n-c_1}]$ is a $(1 - \alpha)100\%$ confidence interval for the median θ . Because the order statistics are continuous random variables, the interval (Y_{c_1+1}, Y_{n-c_1}) is an equivalent confidence interval.

If n is large, then there is a large sample approximation to c_1 . We know from the Central Limit Theorem that $S(\theta)$ is approximately normal with mean $n/2$ and variance $n/4$. Then, using the continuity correction, we obtain the approximation

$$c_1 \approx \frac{n}{2} - \frac{z_{\alpha/2}\sqrt{n}}{2} - \frac{1}{2}, \quad (10.2.37)$$

where $\Phi(-z_{\alpha/2}) = \alpha/2$; see Exercise 10.2.7. In practice, we use the closest integer to c_1 .

Example 10.2.5 (Example 10.2.1, Continued). There are 20 data points in the Shoshoni basket data. The sample median of the width to the length is $0.5(0.628 + 0.654) = 0.641$. Because $0.021 = P_{H_0}(S(0.618) \leq 5)$, a 95.8% confidence interval for θ is the interval $(y_6, y_{15}) = (0.606, 0.672)$, which includes 0.618, the ratio of the width to the length, which characterizes the golden rectangle.

Currently, there is not an intrinsic R function for the one-sample sign analysis. The R function `onesampsgn.R`, which can be downloaded at the site listed in the Preface, computes this analysis. For these data, its default 95% confidence interval is the same as that computed above. ■

EXERCISES

10.2.1. Sketch Figure 10.2.2 for the Shoshoni basket data found in Example 10.2.1. Show the values of the test statistic, the point estimate, and the 95.8% confidence interval of Example 10.2.5 on the sketch.

10.2.2. Show that the test given by (10.2.6) has asymptotically level α ; that is, show that under H_0 ,

$$\frac{S(\theta_0) - (n/2)}{\sqrt{n}/2} \xrightarrow{D} Z,$$

where Z has a $N(0, 1)$ distribution.

10.2.3. Let θ denote the median of a random variable X . Consider testing

$$H_0 : \theta = 0 \text{ versus } H_1 : \theta > 0 .$$

Suppose we have a sample of size $n = 25$.

- (a) Let $S(0)$ denote the sign test statistic. Determine the level of the test: reject H_0 if $S(0) \geq 16$.
- (b) Determine the power of the test in part (a) if X has $N(0.5, 1)$ distribution.
- (c) Assuming X has finite mean $\mu = \theta$, consider the asymptotic test of rejecting H_0 if $\bar{X}/(\sigma/\sqrt{n}) \geq k$. Assuming that $\sigma = 1$, determine k so the asymptotic test has the same level as the test in part (a). Then determine the power of this test for the situation in part (b).

10.2.4. To appreciate the importance of setting the location functional, consider the length of rivers data set, as taken from Tukey (1977). This data set contains the lengths of 141 American rivers in miles and it can be found in the file `lengthriver.rda`.

- (a) Suppose the location functional is the median. Obtain the estimate and a 95% confidence interval for it. Use the confidence interval discussed in Section 10.2.3. Interpret it in terms of the data. Use the R function `onesampsgn.R` for computation.
- (b) Suppose the location functional is the mean. Obtain the estimate and the 95% t -confidence interval for it. Interpret it in terms of the data.
- (c) Obtain the boxplot of the data and sketch the estimates and confidence intervals on it. Discuss.

10.2.5. Recall the definition of a scale functional given in Exercise 10.1.4. Show that the parameter τ_S defined in Theorem 10.2.2 is a scale functional.

10.2.6. Show that the sample mean solves Equation (10.2.32).

10.2.7. Derive the approximation (10.2.37).

10.2.8. Show that the power function of the sign test is nonincreasing for the hypotheses

$$H_0 : \theta = \theta_0 \text{ versus } H_1 : \theta < \theta_0. \quad (10.2.38)$$

10.2.9. Let X_1, X_2, \dots, X_n be a random sample that follows the location model (10.2.1). In this exercise we want to compare the sign tests and t -test of the hypotheses (10.2.2); so we assume the random errors ε_i are symmetrically distributed about 0. Let $\sigma^2 = \text{Var}(\varepsilon_i)$. Hence the mean and the median are the same for this location model. Assume, also, that $\theta_0 = 0$. Consider the large sample version of the t -test, which rejects H_0 in favor of H_1 if $\bar{X}/(\sigma/\sqrt{n}) > z_\alpha$.

- (a) Obtain the power function, $\gamma_t(\theta)$, of the large sample version of the t -test.
- (b) Show that $\gamma_t(\theta)$ is nondecreasing in θ .
- (c) Show that $\gamma_t(\theta_n) \rightarrow 1 - \Phi(z_\alpha - \sigma\theta^*)$, under the sequence of local alternatives (10.2.13).
- (d) Based on part (c), obtain the sample size determination for the t -test to detect θ^* with approximate power γ^* .
- (e) Derive the ARE(S, t) given in (10.2.27).

10.3 Signed-Rank Wilcoxon

Let X_1, X_2, \dots, X_n be a random sample that follows Model (10.2.1). Inference for θ based on the sign test is simple and requires few assumptions about the underlying distribution of X_i . On the other hand, sign procedures have the low efficiency of 0.64 relative to procedures based on the t -test given an underlying normal distribution. In this section, we discuss a nonparametric procedure that does attain high efficiency relative to the t -test. We make the additional assumption that the pdf $f(x)$ of ε_i in Model (10.2.1) is symmetric; i.e., $f(x) = f(-x)$, for all x such that $-\infty < x < \infty$. Hence X_i is symmetrically distributed about θ . Thus, by Theorem 10.1.1, all location parameters are identical.

First, consider the one-sided hypotheses

$$H_0 : \theta = 0 \text{ versus } H_1 : \theta > 0. \quad (10.3.1)$$

There is no loss of generality in assuming that the null hypothesis is $H_0 : \theta = 0$, for if it were $H_0 : \theta = \theta_0$, we would consider the sample $X_1 - \theta_0, \dots, X_n - \theta_0$. Under a symmetric pdf, observations X_i that are the same distance from 0 are equilike and hence should receive the same weight. A test statistic that does this is the **signed-rank Wilcoxon** given by

$$T = \sum_{i=1}^n \text{sgn}(X_i)R|X_i|, \quad (10.3.2)$$

where $R|X_i|$ denotes the rank of X_i among $|X_1|, \dots, |X_n|$, where the rankings are from low to high. Intuitively, under the null hypothesis, we expect half of the X_i s to be positive and half to be negative. Further, the ranks are uniformly distributed on the integers $\{1, 2, \dots, n\}$. Hence values of T around 0 are indicative of H_0 . On the

other hand, if H_1 is true, then we expect more than half of the X_i s to be positive and further, the positive observations are more likely to receive the higher ranks. Thus an appropriate decision rule is

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } T \geq c, \quad (10.3.3)$$

where c is determined by the level α of the test.

Given α , we need the null distribution of T to determine the critical point c . The set of integers $\{-n(n+1)/2, -[n(n+1)/2] + 2, \dots, n(n+1)/2\}$ form the support of T . Also, from Section 10.2, we know that the signs are iid with support $\{-1, 1\}$ and pmf

$$p(-1) = p(1) = \frac{1}{2}. \quad (10.3.4)$$

A key result is the following lemma:

Lemma 10.3.1. *Under H_0 and symmetry about 0 for the pdf, the random variables $|X_1|, \dots, |X_n|$ are independent of the random variables $\text{sgn}(X_1), \dots, \text{sgn}(X_n)$.*

Proof: Because X_1, \dots, X_n is a random sample from the cdf $F(x)$, it suffices to show that $P[|X_i| \leq x, \text{sgn}(X_i) = 1] = P[|X_i| \leq x]P[\text{sgn}(X_i) = 1]$. Due to H_0 and the symmetry of $f(x)$, this follows from the following string of equalities

$$\begin{aligned} P[|X_i| \leq x, \text{sgn}(X_i) = 1] &= P[0 < X_i \leq x] = F(x) - \frac{1}{2} \\ &= [2F(x) - 1]\frac{1}{2} = P[|X_i| \leq x]P[\text{sgn}(X_i) = 1]. \blacksquare \end{aligned}$$

Based on this lemma, the ranks of the $|X_i$ s are independent of the signs of the X_i s. Note that the ranks are a permutation of the integers $1, 2, \dots, n$. By the lemma this independence is true for any permutation. In particular, suppose we use the permutation that orders the absolute values. For example, suppose the observations are $-6.1, 4.3, 7.2, 8.0, -2.1$. Then the permutation $5, 2, 1, 3, 4$ orders the absolute values; that is, the fifth observation is the smallest in absolute value, the second observation is the next smallest, etc. This permutation is called the **anti-ranks**, which we denote generally by i_1, i_2, \dots, i_n . Using the anti-ranks, we can write T as

$$T = \sum_{j=1}^n j \text{sgn}(X_{i_j}), \quad (10.3.5)$$

where, by Lemma 10.3.1, $\text{sgn}(X_{i_j})$ are iid with support $\{-1, 1\}$ and pmf (10.3.4).

Based on this observation, for s such that $-\infty < s < \infty$, the mgf of T is

$$\begin{aligned}
E[\exp\{sT\}] &= E\left[\exp\left\{\sum_{j=1}^n sj \operatorname{sgn}(X_{i_j})\right\}\right] \\
&= \prod_{j=1}^n E[\exp\{sj \operatorname{sgn}(X_{i_j})\}] \\
&= \prod_{j=1}^n \left(\frac{1}{2}e^{-sj} + \frac{1}{2}e^{sj}\right) \\
&= \frac{1}{2^n} \prod_{j=1}^n (e^{-sj} + e^{sj}). \tag{10.3.6}
\end{aligned}$$

Because the mgf does not depend on the underlying symmetric pdf $f(x)$, the test statistic T is distribution free under H_0 . Although the pmf of T cannot be obtained in closed form, this mgf can be used to generate the pmf for a specified n ; see Exercise 10.3.1.

Because the $\operatorname{sgn}(X_{i_j})$ s are mutually independent with mean zero, it follows that $E_{H_0}[T] = 0$. Further, because the variance of $\operatorname{sgn}(X_{i_j})$ is 1, we have

$$\operatorname{Var}_{H_0}(T) = \sum_{j=1}^n \operatorname{Var}_{H_0}(j \operatorname{sgn}(X_{i_j})) = \sum_{j=1}^n j^2 = n(n+1)(2n+1)/6.$$

We summarize these results in the following theorem:

Theorem 10.3.1. *Assume that Model (10.2.1) is true for the random sample X_1, \dots, X_n . Assume also that the pdf $f(x)$ is symmetric about 0. Then under H_0 ,*

$$T \text{ is distribution free with a symmetric pmf} \tag{10.3.7}$$

$$E_{H_0}[T] = 0 \tag{10.3.8}$$

$$\operatorname{Var}_{H_0}(T) = \frac{n(n+1)(2n+1)}{6} \tag{10.3.9}$$

$$\frac{T}{\sqrt{\operatorname{Var}_{H_0}(T)}} \text{ has an asymptotically } N(0, 1) \text{ distribution.} \tag{10.3.10}$$

Proof: The first part of (10.3.7) and the expressions (10.3.8) and (10.3.9) were derived above. The asymptotic distribution of T certainly is plausible and its proof can be found in more advanced books. To obtain the second part of (10.3.7), we need to show that the distribution of T is symmetric about 0. But by the mgf of T , (10.3.6), we have

$$E[\exp\{s(-T)\}] = E[\exp\{(-s)T\}] = E[\exp\{sT\}].$$

Hence T and $-T$ have the same distribution, so T is symmetrically distributed about 0. ■

Note that the support of T is much denser than that of the sign test, so the normal approximation is good even for a sample size of 10.

There is another formulation of T that is convenient. Let T^+ denote the sum of the ranks of the positive X_i s. Then, because the sum of all ranks is $n(n+1)/2$, we have

$$\begin{aligned} T &= \sum_{i=1}^n \text{sgn}(X_i)R|X_i| = \sum_{X_i>0} R|X_i| - \sum_{X_i<0} R|X_i| \\ &= 2 \sum_{X_i>0} R|X_i| - \frac{n(n+1)}{2} \\ &= 2T^+ - \frac{n(n+1)}{2}. \end{aligned} \tag{10.3.11}$$

Hence T^+ is a linear function of T and thus is an equivalent formulation of the signed-rank test statistic T . For the record, we note the null mean and variance of T^+ :

$$E_{H_0}(T^+) = \frac{n(n+1)}{4} \quad \text{and} \quad \text{Var}_{H_0}(T^+) = \frac{n(n+1)(2n+1)}{24}. \tag{10.3.12}$$

The intrinsic R function `wilcox.test` computes the signed-rank analysis, returning the test statistic T^+ and the p -value. If the sample is in the R vector `x` then the signed-rank test of the hypotheses (10.3.1) is computed by the R command `wilcox.test(x, alt="greater")`. The arguments for the other one-sided and the two-sided hypotheses are respectively `alt="less"` and `alt="two.sided"`. To compute the signed-rank test of the hypotheses $H_0 : \theta = \theta_0$ versus $H_1 : \theta \neq \theta_0$, use the command `wilcox.test(x, alt="two.sided", mu=theta0)`. Also, the R call `psignrank(y, n)` computes the cdf of T^+ at y .

Example 10.3.1 (*Zea mays* Data of Darwin). Reconsider the data set discussed in Example 4.5.1. Recall that W_i is the difference in heights of the cross-fertilized plant minus the self-fertilized plant in pot i , for $i = 1, \dots, 15$. Let θ be the location parameter and consider the one-sided hypotheses

$$H_0 : \theta = 0 \text{ versus } H_1 : \theta > 0. \tag{10.3.13}$$

Table 10.3.1 displays the data and the signed ranks.

Adding up the ranks of the positive items in column 5 of Table 10.3.1, we obtain $T^+ = 96$. Using the exact distribution, the R command is `1-psignrank(95, 15)`, we obtain the p -value, $\hat{p} = P_{H_0}(T^+ \geq 96) = 0.021$. For comparison, the asymptotic p -value, using the continuity correction is

$$\begin{aligned} P_{H_0}(T^+ \geq 96) &= P_{H_0}(T^+ \geq 95.5) \approx P\left(Z \geq \frac{95.5 - 60}{\sqrt{15 \cdot 16 \cdot 31/24}}\right) \\ &= P(Z \geq 2.016) = 0.022, \end{aligned}$$

which is quite close to the exact value of 0.021.

Suppose the R vector `ds` contains the paired differences between cross and self-fertilized. Then the R command `wilcox.test(ds, alt="greater")` computes the

Table 10.3.1: Signed Ranks for Darwin Data, Example 10.3.1

Pot	Cross-Fertilized	Self-Fertilized	Difference	Signed-Rank
1	23.500	17.375	6.125	11
2	12.000	20.375	-8.375	-14
3	21.000	20.000	1.000	2
4	22.000	20.000	2.000	4
5	19.125	18.375	0.750	1
6	21.550	18.625	2.925	5
7	22.125	18.625	3.500	7
8	20.375	15.250	5.125	9
9	18.250	16.500	1.750	3
10	21.625	18.000	3.625	8
11	23.250	16.250	7.000	12
12	21.000	18.000	3.000	6
13	22.125	12.750	9.375	15
14	23.000	15.500	7.500	13
15	12.000	18.000	-6.000	-10

value of T^+ along with the p -value. The computed values are the same as those computed above. ■

There is another formulation of T^+ which is useful for obtaining the properties of the Wilcoxon signed-rank test and confidence intervals for θ . Let $X_i > 0$ and consider all X_j such that $-X_i < X_j < X_i$. Thus all the averages $(X_i + X_j)/2$, under these restrictions, are positive, including $(X_i + X_i)/2$. From the restriction, though, the number of these positive averages is simply the $R|X_i|$. Doing this for all $X_i > 0$, we obtain

$$T^+ = \#\{i \leq j \mid (X_j + X_i)/2 > 0\}. \quad (10.3.14)$$

The pairwise averages $(X_j + X_i)/2$ are often called the *Walsh averages*. Hence the signed-rank Wilcoxon can be obtained by counting the number of positive Walsh averages.

Based on the identity (10.3.14), we obtain the corresponding process. Let

$$T^+(\theta) = \#\{i \leq j \mid [(X_j - \theta) + (X_i - \theta)]/2 > 0\} = \#\{i \leq j \mid (X_j + X_i)/2 > \theta\}. \quad (10.3.15)$$

The process associated with $T^+(\theta)$ is much like the sign process, (10.2.9). Let $W_1 < W_2 < \dots < W_{n(n+1)/2}$ denote the $n(n+1)/2$ ordered Walsh averages. Then a graph of $T^+(\theta)$ would appear as in Figure 10.2.2, except the ordered Walsh averages would be on the horizontal axis and the largest value on the vertical would be $n(n+1)/2$. Hence the function $T^+(\theta)$ is a decreasing step function of θ , which steps down one unit at each Walsh average. This observation greatly simplifies the discussion on the properties of the signed-rank Wilcoxon.

Let c_α denote the critical value of a level α test of the hypotheses (10.3.1) based on the signed-rank test statistic T^+ ; i.e., $\alpha = P_{H_0}(T^+ \geq c_\alpha)$. Let $\gamma_{SW}(\theta) = P_\theta(T^+ \geq c_\alpha)$, for $\theta \geq \theta_0$, denote the power function of the test. The translation property, Lemma 10.2.1, holds for the signed-rank Wilcoxon. Hence, as in Theorem 10.2.1, the power function is a nondecreasing function of θ . In particular, the signed-rank Wilcoxon test is an unbiased test for the one-sided hypotheses (10.3.1).

10.3.1 Asymptotic Relative Efficiency

We investigate the efficiency of the signed-rank Wilcoxon by first determining its efficacy. Without loss of generality, we can assume that $\theta_0 = 0$. Consider the same sequence of local alternatives discussed in the last section; i.e.,

$$H_0 : \theta = 0 \text{ versus } H_{1n} : \theta_n = \frac{\delta}{\sqrt{n}}, \quad (10.3.16)$$

where $\delta > 0$. Contemplate the modified statistic, which is the average of $T^+(\theta)$,

$$\bar{T}^+(\theta) = \frac{2}{n(n+1)} T^+(\theta). \quad (10.3.17)$$

Then, by (10.3.12),

$$E_0[\bar{T}^+(0)] = \frac{2}{n(n+1)} \frac{n(n+1)}{4} = \frac{1}{2} \quad \text{and} \quad \sigma_{\bar{T}^+}^2(0) = \text{Var}_0[\bar{T}^+(0)] = \frac{2n+1}{6n(n+1)}. \quad (10.3.18)$$

Let $a_n = 2/n(n+1)$. Note that we can decompose $\bar{T}^+(\theta_n)$ into two parts as

$$\bar{T}^+(\theta_n) = a_n S(\theta_n) + a_n \sum_{i < j} I(X_i + X_j > 2\theta_n) = a_n S(\theta_n) + a_n T^*(\theta_n), \quad (10.3.19)$$

where $S(\theta)$ is the sign process (10.2.9) and

$$T^*(\theta_n) = \sum_{i < j} I(X_i + X_j > 2\theta_n). \quad (10.3.20)$$

To obtain the efficacy, we require the mean

$$\mu_{\bar{T}^+}(\theta_n) = E_{\theta_n}[\bar{T}^+(0)] = E_0[\bar{T}^+(-\theta_n)]. \quad (10.3.21)$$

But by (10.2.14), $a_n E_0(S(-\theta_n)) = a_n n(2^{-1} - F(-\theta_n)) \rightarrow 0$. Hence we need only be concerned with the second term in (10.3.19). But note that the Walsh averages in $T^*(\theta)$ are identically distributed. Thus

$$a_n E_0(T^*(-\theta_n)) = a_n \binom{n}{2} P_0(X_1 + X_2 > -2\theta_n). \quad (10.3.22)$$

This latter probability can be expressed as follows:

$$\begin{aligned}
 P_0(X_1 + X_2 > -2\theta_n) &= E_0[P_0(X_1 > -2\theta_n - X_2 | X_2)] = E_0[1 - F(-2\theta_n - X_2)] \\
 &= \int_{-\infty}^{\infty} [1 - F(-2\theta_n - x)] f(x) dx \\
 &= \int_{-\infty}^{\infty} F(2\theta_n + x) f(x) dx \\
 &\approx \int_{-\infty}^{\infty} [F(x) + 2\theta_n f(x)] f(x) dx \\
 &= \frac{1}{2} + 2\theta_n \int_{-\infty}^{\infty} f^2(x) dx,
 \end{aligned} \tag{10.3.23}$$

where we have used the facts that X_1 and X_2 are iid and symmetrically distributed about 0, and the mean value theorem. Hence

$$\mu_{\bar{T}^+}(\theta_n) \approx a_n \binom{n}{2} \left(\frac{1}{2} + 2\theta_n \int_{-\infty}^{\infty} f^2(x) dx \right). \tag{10.3.24}$$

Putting (10.3.18) and (10.3.24) together, we have the efficacy

$$c_{T^+} = \lim_{n \rightarrow \infty} \frac{\mu'_{\bar{T}^+}(0)}{\sqrt{n}\sigma_{\bar{T}^+}(0)} = \sqrt{12} \int_{-\infty}^{\infty} f^2(x) dx. \tag{10.3.25}$$

In a more advanced text, this development can be made into a rigorous argument for the following asymptotic power lemma.

Theorem 10.3.2 (Asymptotic Power Lemma). *Consider the sequence of hypotheses (10.3.16). The limit of the power function of the large sample, size α , signed-rank Wilcoxon test is given by*

$$\lim_{n \rightarrow \infty} \gamma_{SR}(\theta_n) = 1 - \Phi(z_\alpha - \delta\tau_W^{-1}), \tag{10.3.26}$$

where $\tau_W = 1/[\sqrt{12} \int_{-\infty}^{\infty} f^2(x) dx]$ is the reciprocal of the efficacy c_{T^+} and $\Phi(z)$ is the cdf of a standard normal random variable.

As shown in Exercise 10.3.10, the parameter τ_W is a scale functional.

The arguments used in the determination of the sample size in Section 10.2 for the sign test were based on the asymptotic power lemma; hence, these arguments follow almost verbatim for the signed-rank Wilcoxon. In particular, the sample size needed so that a level α signed-rank Wilcoxon test of the hypotheses (10.3.1) can detect the alternative $\theta = \theta_0 + \theta^*$ with approximate probability γ^* is

$$n_W = \left(\frac{(z_\alpha - z_{\gamma^*})\tau_W}{\theta^*} \right)^2. \tag{10.3.27}$$

Using (10.2.26), the ARE between the signed-rank Wilcoxon test and the t -test based on the sample mean is

$$\text{ARE}(T, t) = \frac{n_t}{n_T} = \frac{\sigma^2}{\tau_W^2}. \tag{10.3.28}$$

We now derive some AREs between the Wilcoxon and the t -test. As noted above, the parameter τ_W is a scale functional and, hence, varies directly with scale transformations of the form aX , for $a > 0$. Likewise, the standard deviation σ is also a scale functional. Therefore, because the AREs are ratios of scale functionals, they are scale invariant. Hence, for derivations of AREs, we can select a pdf with a convenient choice of scale. For example, if we are considering an ARE at the normal distribution, we can work with the $N(0, 1)$ pdf.

Example 10.3.2 (ARE(W, t) at the normal distribution). If $f(x)$ is a $N(0, 1)$ pdf, then

$$\begin{aligned}\tau_W^{-1} &= \sqrt{12} \int_{-\infty}^{\infty} \left(\frac{1}{\sqrt{2\pi}} \exp\{-x^2/2\} \right)^2 dx \\ &= \frac{\sqrt{12}}{\sqrt{2}\sqrt{2\pi}} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}(1/\sqrt{2})} \exp\{-2^{-1}(x/(1/\sqrt{2}))^2\} dx = \sqrt{\frac{3}{\pi}}\end{aligned}$$

Hence $\tau_W^2 = \pi/3$. Since $\sigma = 1$, we have

$$\text{ARE}(W, t) = \frac{\sigma^2}{\tau_W^2} = \frac{3}{\pi} = 0.955. \quad (10.3.29)$$

As discussed above, this ARE holds for all normal distributions. Hence, at the normal distribution, the Wilcoxon signed-rank test is 95.5% efficient as the t -test. The Wilcoxon is called a **highly efficient** procedure. ■

Example 10.3.3 (ARE(W, t) at a Family of Contaminated Normals). For this example, suppose that $f(x)$ is the pdf of a contaminated normal distribution. For convenience, we use the standardized pdf given in expression (10.2.30) with $b = 1$. Recall that for this distribution, $(1 - \epsilon)$ proportion of the time the sample is drawn from a $N(0, 1)$ distribution, while ϵ proportion of the time the sample is drawn from a $N(0, \sigma_c^2)$ distribution. Recall that the variance is $\sigma^2 = 1 + \epsilon(\sigma_c^2 - 1)$. Note that the formula for the pdf $f(x)$ is given in expression (3.4.17). In Exercise 10.3.5 it is shown that

$$\int_{-\infty}^{\infty} f^2(x) dx = \frac{(1 - \epsilon)^2}{2\sqrt{\pi}} + \frac{\epsilon^2}{6\sqrt{\pi}} + \frac{\epsilon(1 - \epsilon)}{2\sqrt{\pi}}. \quad (10.3.30)$$

Based on this, an expression for the ARE can be obtained; see Exercise 10.3.5. We used this expression to determine the AREs between the Wilcoxon and the t -tests for the situations with $\sigma_c = 3$ and ϵ varying from 0.00–0.25, displaying them in Table 10.3.2. For convenience, we have also displayed the AREs between the sign test and these two tests.

Note that the signed-rank Wilcoxon is more efficient than the t -test even at 1% contamination and increases to 150% efficiency for 15% contamination. ■

10.3.2 Estimating Equations Based on Signed-Rank Wilcoxon

For the sign procedure, the estimation of θ was based on minimizing the L_1 norm. The estimator associated with the signed-rank test minimizes another norm, which

Table 10.3.2: AREs among the sign, the Signed-Rank Wilcoxon, and the t -Tests for Contaminated Normals with $\sigma_c = 3$ and Proportion of Contamination ϵ

ϵ	0.00	0.01	0.02	0.03	0.05	0.10	0.15	0.25
ARE(W, t)	0.955	1.009	1.060	1.108	1.196	1.373	1.497	1.616
ARE(S, t)	0.637	0.678	0.719	0.758	0.833	0.998	1.134	1.326
ARE(W, S)	1.500	1.487	1.474	1.461	1.436	1.376	1.319	1.218

is discussed in Exercises 10.3.7 and 10.3.8. Recall that we also show that the location estimator based on the sign test could be obtained by inverting the test. Considering this for the Wilcoxon, the estimator $\hat{\theta}_W$ solves

$$T^+(\hat{\theta}_W) = \frac{n(n+1)}{4}. \quad (10.3.31)$$

Using the description of the function $T^+(\theta)$ after its definition, (10.3.15), it is easily seen that $\hat{\theta}_W = \text{median}\{(X_i + X_j)/2\}$; i.e., the median of the Walsh averages. This is often called the Hodges–Lehmann estimator because of several seminal articles by Hodges and Lehmann on the properties of this estimator; see Hodges and Lehmann (1963).

The R function `wilcox.test` computes the Hodges–Lehmann estimate. To illustrate its computation, consider the Darwin data in Example 10.3.1. Let the R vector `ds` contain the paired differences, Cross – Self. The R code segment given by `wilcox.test(ds, conf.int=T)` then computes the Hodges–Lehmann estimate to be 3.1375. So we estimate the difference in heights to be 3.1375 inches.

Once again, we can use practically the same argument that we used for the sign process to obtain the asymptotic distribution of the Hodges–Lehmann estimator. We summarize the result in the next theorem.

Theorem 10.3.3. Consider a random sample $X_1, X_2, X_3, \dots, X_n$ which follows Model (10.2.1). Suppose that $f(x)$ is symmetric about 0. Then

$$\sqrt{n}(\hat{\theta}_W - \theta) \rightarrow N(0, \tau_W^2), \quad (10.3.32)$$

where $\tau_W = \left(\sqrt{12} \int_{-\infty}^{\infty} f^2(x) dx\right)^{-1}$.

Using this theorem, the AREs based on asymptotic variances for the signed-rank Wilcoxon are the same as those defined above.

10.3.3 Confidence Interval for the Median

Because of the similarity between the processes $S(\theta)$ and $T^+(\theta)$, confidence intervals for θ based on the signed-rank Wilcoxon follow the same way as do those based on $S(\theta)$. For a given level α , let cw_1 , an integer, denote the critical point of the signed-rank Wilcoxon distribution such that $P_\theta[T^+(\theta) \leq cw_1] = \alpha/2$. As in Section 10.2.3,

we then have that

$$\begin{aligned} 1 - \alpha &= P_\theta[c_{W1} < T^+(\theta) < n - c_{W1}] \\ &= P_\theta[W_{c_{W1}+1} \leq \theta < W_{m-c_{W1}}], \end{aligned} \quad (10.3.33)$$

where $m = n(n+1)/2$ denotes the number of Walsh averages. Therefore, the interval $[W_{c_{W1}+1}, W_{m-c_{W1}}]$ is a $(1 - \alpha)100\%$ confidence interval for θ .

We can use the asymptotic null distribution of T^+ , (10.3.10), to obtain the following approximation to c_{W1} . As shown in Exercise 10.3.6,

$$c_{W1} \approx \frac{n(n+1)}{4} - z_{\alpha/2} \sqrt{\frac{n(n+1)(2n+1)}{24}} - \frac{1}{2}, \quad (10.3.34)$$

where $\Phi(-z_{\alpha/2}) = \alpha/2$. In practice, we use the closest integer to c_{W1} .

In R, this confidence interval is computed by the R function `wilcox.test`. For instance, for the Darwin data let the R vector `ds` contain the paired differences, Cross – Self. Then the call `wilcox.test(ds, conf.int=T, conf.level=.95)` computes a 95% confidence interval for the median of the differences. Its computation results in the interval (0.5000, 5.2125). Hence, with confidence 95%, we estimate that cross-fertilized *zea mays* are between 0.5 to 5.2 inches taller than self-fertilized ones.

10.3.4 Monte Carlo Investigation

The AREs derived in this chapter are asymptotic. In this section, we describe Monte Carlo techniques which investigate the relative efficiency between estimators for finite sample sizes. Comparisons are performed over families of distributions and a selection of sample sizes. Each combination of distribution and sample size is referred to as a **situation**. We also select a simulation size n_s , which is usually quite large. We next describe a typical simulation to investigate the relative efficiency between two estimators.

For notation, let X_1, \dots, X_n be a random sample that follows the location model, (10.2.1), i.e.,

$$X_i = \theta + e_i, \quad i = 1, \dots, n, \quad (10.3.35)$$

where e_i 's are iid with pdf $f(x)$ and $f(x)$ is symmetric about 0. For our discussion, consider the case of two location estimators of θ , which we denote by $\hat{\theta}_1$ and $\hat{\theta}_2$. Since these are location estimators, we further assume without loss of generality that the true $\theta = 0$.

Let n denote the sample size and let $f(x)$ denote the pdf for a given situation. Then n_s independent random samples of size n are generated from $f(x)$. For the i th sample, denote the estimates by $\hat{\theta}_{1i}$ and $\hat{\theta}_{2i}$, $i = 1, \dots, n_s$. For the estimator $\hat{\theta}_j$, consider the mean square error over the simulations given by

$$\text{MSE}_j = \frac{1}{n_s} \sum_{i=1}^{n_s} \hat{\theta}_{ji}^2, \quad j = 1, 2. \quad (10.3.36)$$

As sketched in Exercise 10.3.2, under the assumptions of symmetry and location estimators, MSE_j is a consistent estimator of the variance of $\widehat{\theta}_j$ for a sample of size n . Hence, the estimate of the relative efficiency (RE_n) between the estimators $\widehat{\theta}_1$ and $\widehat{\theta}_2$ at sample size n is the ratio

$$\widehat{\text{RE}}_n(\widehat{\theta}_1, \widehat{\theta}_2) = \frac{\text{MSE}_2}{\text{MSE}_1}. \quad (10.3.37)$$

To illustrate this discussion, consider a study comparing the Hodges–Lehmann and sample mean estimators over the family of contaminated normal distributions with rate of contamination ϵ and the standard deviation ratio σ_c , where we are using the notation of Example 10.3.3. The R function `rcn.R` is used to generate samples from a contaminated normal. The following R function `aresimcn.R` computes the simulation and returns the estimate of RE_n :

```
aresimcn <- function(n, nsims, eps, vc){
  chl <- c(); cxbar <- c()
  for(i in 1:nsims){
    x <- rcn(n, eps, vc)
    chl <- c(chl, wilcox.test(x, conf.int=T)$est)
    cxbar <- c(cxbar, t.test(x, conf.int=T)$est)
  }
  aresimcn <- mses(cxbar, 0)/mses(chl, 0)
  return(aresimcn)}
```

The function `mses.R` computes the MSEs, (10.3.36). All three functions are at the site listed in the Preface.

For a specific situation set $n = 30$ with samples generated from the contaminated normal distribution with rate of contamination $\epsilon = 0.25$ and the standard deviation ratio $\sigma_c = 3$. From Table 10.3.2, the asymptotic ARE is 1.616. Our run of the function `aresimcn.R` using 10,000 simulations at these settings produced the estimate 1.561 for the relative efficiency at sample size $n = 30$. This is close to the asymptotic value. The actual call was `aresimcn(30, 10000, .25, 3)`. We also ran the situation with $\epsilon = 0.20$ and $\sigma_c = 25$. In this case, the estimated RE for samples of size $n = 30$ was 40.934; i.e., we estimate that the Hodges–Lehmann estimator is 41% more efficient than the sample mean at this contaminated normal distribution for a sample size of 30.

EXERCISES

10.3.1. (a) For $n = 3$, expand the mgf (10.3.6) to show that the distribution of the signed-rank Wilcoxon is given by

j	−6	−4	−2	0	2	4	6
$P(T = j)$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{2}{8}$	$\frac{1}{8}$	$\frac{1}{8}$	$\frac{1}{8}$

(b) Obtain the distribution of the signed-rank Wilcoxon for $n = 4$.

10.3.2. Consider the location Model (10.3.35). Assume that the pdf of the random errors, $f(x)$, is symmetric about 0. Let $\hat{\theta}$ be a location estimator of θ . Assume that $E(\hat{\theta}^4)$ exists.

- (a) Show that $\hat{\theta}$ is an unbiased estimator of θ .

Hint: Assume without loss of generality that $\theta = 0$; start with $E(\hat{\theta}) = E[\hat{\theta}(X_1, \dots, X_n)]$; and use the fact that X_i is symmetrically distributed about 0.

- (b) As in Section 10.3.4, suppose we generate n_s independent samples of size n from the pdf $f(x)$ which is symmetric about 0. For the i th sample, let $\hat{\theta}_i$ be the estimate of θ . Show that $n_s^{-1} \sum_{i=1}^{n_s} \hat{\theta}_i^2 \rightarrow V(\hat{\theta})$, in probability.

10.3.3. Modify the code of the R function `aresimcn.R` so it samples from the $N(0, 1)$ distribution. Estimate the RE between the Hodges–Lehmann estimator and \bar{X} for the sample sizes $n = 15, 25, 50$ and 100 . Use 10,000 simulations for each sample size. Compare your results to the asymptotic ARE which is 0.955.

10.3.4. Consider the self rival data presented in Exercise 4.6.5. Recall that it is a paired design consisting of the pairs $(\text{Self}_i, \text{Rival}_i)$, for $i = 1, \dots, 20$, where Self_i and Rival_i are the running times for circling the bases for the respective treatments of Self motivation and Rival motivation. The data can be found in the file `selfrival.rda`. Let $X_i = \text{Self}_i - \text{Rival}_i$ denote the paired differences and model these in the location model as $X_i = \theta + e_i$. Consider the hypotheses $H_0 : \theta = 0$ versus $H_1 : \theta \neq 0$.

- (a) Obtain the signed-rank test statistic and p -value for these hypotheses. State the conclusion (in terms of the data) using the level 0.05.
- (b) Obtain the t test statistic and p -value and conclude using the level 0.05.
- (c) To see the effect that an outlier has on these two analyses, change the 20th rival time from 17.88 to 178.8. Comment on how the analyses changed due to the outlier.
- (d) Obtain 95% confidence intervals for θ for both analyses for the original data and the changed data. Comment on how the confidence intervals changed due to the outlier.

10.3.5. Assume that $f(x)$ has the contaminated normal pdf given in expression (3.4.17). Derive expression (10.3.30) and use it to obtain $\text{ARE}(W, t)$ for this pdf.

10.3.6. Use the asymptotic null distribution of T^+ , (10.3.10), to obtain the approximation (10.3.34) to $cw1$.

10.3.7. For a vector $\mathbf{v} \in R^n$, define the function

$$\|\mathbf{v}\| = \sum_{i=1}^n R(|v_i|)|v_i|. \quad (10.3.38)$$

Show that this function is a norm on R^n ; that is, it satisfies the properties

1. $\|\mathbf{v}\| \geq 0$ and $\|\mathbf{v}\| = 0$ if and only if $\mathbf{v} = \mathbf{0}$.
2. $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$, for all a such that $-\infty < a < \infty$.
3. $\|\mathbf{u} + \mathbf{v}\| \leq \|\mathbf{u}\| + \|\mathbf{v}\|$, for all $\mathbf{u}, \mathbf{v} \in R^n$.

For the triangle inequality, use the anti-rank version, that is,

$$\|\mathbf{v}\| = \sum_{j=1}^n j|v_{i_j}|. \quad (10.3.39)$$

Then use the following fact: If we have two sets of n numbers, for example, $\{t_1, t_2, \dots, t_n\}$ and $\{s_1, s_2, \dots, s_n\}$, then the largest sum of pairwise products, one from each set, is given by $\sum_{j=1}^n t_{i_j} s_{k_j}$, where $\{i_j\}$ and $\{k_j\}$ are the anti-ranks for the t_i and s_i , respectively, i.e., $t_{i_1} \leq t_{i_2} \leq \dots \leq t_{i_n}$ and $s_{k_1} \leq s_{k_2} \leq \dots \leq s_{k_n}$.

10.3.8. Consider the norm given in Exercise 10.3.7. For a location model, define the estimate of θ to be

$$\hat{\theta} = \operatorname{Argmin}_{\theta} \|X_i - \theta\|. \quad (10.3.40)$$

Show that $\hat{\theta}$ is the Hodges–Lehmann estimate, i.e., satisfies (10.4.27).

Hint: Use the anti-rank version (10.3.39) of the norm when differentiating with respect to θ .

10.3.9. Prove that a pdf (or pmf) $f(x)$ is symmetric about 0 if and only if its mgf is symmetric about 0, provided the mgf exists.

10.3.10. In Exercise 10.1.4, we defined the term scale functional. Show that the parameter τ_W , (10.3.26), is a scale functional.

10.4 Mann–Whitney–Wilcoxon Procedure

Suppose X_1, X_2, \dots, X_{n_1} is a random sample from a distribution with a continuous cdf $F(x)$ and pdf $f(x)$ and Y_1, Y_2, \dots, Y_{n_2} is a random sample from a distribution with a continuous cdf $G(x)$ and pdf $g(x)$. For this situation there is a natural null hypothesis given by $H_0 : F(x) = G(x)$ for all x ; i.e., the samples are from the same distribution. What about alternative hypotheses besides the general alternative not H_0 ? An interesting alternative is that X is **stochastically larger** than Y , which is defined by $G(x) \geq F(x)$, for all x , with strict inequality for at least one x . This alternative hypothesis is discussed in the exercises.

For the most part in this section, however, we consider the location model. In this case, $G(x) = F(x - \Delta)$ for some value of Δ . Hence the null hypothesis becomes $H_0 : \Delta = 0$. The parameter Δ is often called the **shift** between the distributions and the distribution of Y is the same as the distribution of $X + \Delta$; that is,

$$P(Y \leq y) = P(X + \Delta \leq y) = F(y - \Delta). \quad (10.4.1)$$

If $\Delta > 0$, then Y is stochastically larger than X ; see Exercise 10.4.8.

In the shift case, the parameter Δ is independent of what location functional is used. To see this, suppose we select an arbitrary location functional for X , say, $T(F_X)$. Then we can write X_i as

$$X_i = T(F_X) + \varepsilon_i, \quad (10.4.2)$$

where $\varepsilon_1, \dots, \varepsilon_{n_1}$ are iid with $T(F_\varepsilon) = 0$. By (10.4.1) it follows that

$$Y_j = T(F_X) + \Delta + \varepsilon_j, \quad j = 1, 2, \dots, n_2. \quad (10.4.3)$$

Hence $T(F_Y) = T(F_X) + \Delta$. Therefore, $\Delta = T(F_Y) - T(F_X)$ for any location functional; i.e., Δ is the same no matter what functional is chosen to model location.

Assume then that the shift model, (10.4.1), holds for the two samples. Alternatives of interest are the usual one- and two-sided alternatives. For convenience we pick on the one-sided hypotheses given by

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0. \quad (10.4.4)$$

The exercises consider the other hypotheses. Under H_0 , the distributions of X and Y are the same, and we can combine the samples to have one large sample of $n = n_1 + n_2$ observations. Suppose we rank the combined samples from 1 to n and consider the statistic

$$W = \sum_{j=1}^{n_2} R(Y_j), \quad (10.4.5)$$

where $R(Y_j)$ denotes the rank of Y_j in the combined sample of n items. This statistic is often called the **Mann–Whitney–Wilcoxon** (MW χ) statistic. Under H_0 the ranks are uniformly distributed between the X_i s and the Y_j s; however, under $H_1 : \Delta > 0$, the Y_j s should get most of the large ranks. Hence an intuitive rejection rule is given by

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } W \geq c. \quad (10.4.6)$$

We now discuss the null distribution of W , which enables us to select c for the decision rule based on a specified level α . Under H_0 , the ranks of the Y_j s are equilikely to be any subset of size n_2 from a set of n elements. Recall that there are $\binom{n}{n_2}$ such subsets; therefore, if $\{r_1, \dots, r_{n_2}\}$ is a subset of size n_2 from $\{1, \dots, n\}$, then

$$P[R(Y_1) = r_1, \dots, R(Y_{n_2}) = r_{n_2}] = \binom{n}{n_2}^{-1}. \quad (10.4.7)$$

This implies that the statistic W is distribution free under H_0 . Although the null distribution of W cannot be obtained in closed form, there are recursive algorithms which obtain this distribution; see Chapter 2 of the text by Hettmansperger and McKean (2011). In the same way, the distribution of a single rank $R(Y_j)$ is uniformly distributed on the integers $\{1, \dots, n\}$, under H_0 . Hence we immediately have

$$E_{H_0}(W) = \sum_{j=1}^{n_2} E_{H_0}(R(Y_j)) = \sum_{j=1}^{n_2} \sum_{i=1}^n i \frac{1}{n} = \sum_{j=1}^{n_2} \frac{n(n+1)}{2n} = \frac{n_2(n+1)}{2}.$$

The variance is displayed below (10.4.10) and a derivation of a more general case is given in Section 10.5. It also can be shown that W is asymptotically normal. We summarize these items in the theorem below.

Theorem 10.4.1. Suppose X_1, X_2, \dots, X_{n_1} is a random sample from a distribution with a continuous cdf $F(x)$ and Y_1, Y_2, \dots, Y_{n_2} is a random sample from a distribution with a continuous cdf $G(x)$. Suppose $H_0 : F(x) = G(x)$, for all x . If H_0 is true, then

$$W \text{ is distribution free with a symmetric pmf} \quad (10.4.8)$$

$$E_{H_0}[W] = \frac{n_2(n+1)}{2} \quad (10.4.9)$$

$$\text{Var}_{H_0}(W) = \frac{n_1 n_2 (n+1)}{12} \quad (10.4.10)$$

$$\frac{W - n_2(n+1)/2}{\sqrt{\text{Var}_{H_0}(W)}} \text{ has an asymptotically } N(0, 1) \text{ distribution.} \quad (10.4.11)$$

The only item of the theorem not discussed above is the symmetry of the null distribution, which we show later. First, consider this example:

Example 10.4.1 (Water Wheel Data Set). In an experiment discussed in Abebe et al. (2001), mice were placed in a wheel that is partially submerged in water. If they keep the wheel moving, they avoid the water. The response is the number of wheel revolutions per minute. Group 1 is a placebo group, while Group 2 consists of mice that are under the influence of a drug. The data are

Group 1 X	2.3	0.3	5.2	3.1	1.1	0.9	2.0	0.7	1.4	0.3
Group 2 Y	0.8	2.8	4.0	2.4	1.2	0.0	6.2	1.5	28.8	0.7

The data are in the file `waterwheel.rda`. Comparison boxplots of the data (asked for in Exercise 10.4.9) show that the two data sets are similar except for the large outlier in the treatment group. A two-sided hypothesis seems appropriate in this case. Notice that a few of the data points in the data set have the same value (are tied). This happens in real data sets. We follow the usual practice and use the average of the ranks involved to break ties. For example, the observations $x_2 = x_{10} = 0.3$ are tied and the ranks involved for the combined data are 2 and 3. Hence we use 2.5 for the ranks of each of these observations. Continuing in this way, the Wilcoxon test statistic is $w = \sum_{j=1}^{10} R(y_j) = 116.50$. The null mean and variance of W are 105 and 175, respectively. The asymptotic test statistic is $z = (116.5 - 105)/\sqrt{175} = 0.869$ with $p\text{-value } 2*(1-\text{pnorm}(0.869)) = 0.3848$. Hence H_0 would not be rejected. The test confirms the comparison boxplots of the data. The t -test based on the difference in means is discussed in Exercise 10.4.9. In Example 10.4.2, we discuss the R computation. ■

We next want to derive some properties of the test statistic and then use these properties to discuss point estimation and confidence intervals for Δ . As in the last section, another way of writing W proves helpful in these regards. Without loss of generality, assume that the Y_j s are in order. Recall that the distributions

of X_i and Y_j are continuous; hence, we treat the observations as distinct. Thus $R(Y_j) = \#\{X_i < Y_j\} + \#\{Y_i \leq Y_j\}$. This leads to

$$\begin{aligned} W = \sum_{j=1}^{n_2} R(Y_j) &= \sum_{j=1}^{n_2} \#\{X_i < Y_j\} + \sum_{j=1}^{n_2} \#\{Y_i \leq Y_j\} \\ &= \#\{Y_j > X_i\} + \frac{n_2(n_2+1)}{2}. \end{aligned} \quad (10.4.12)$$

Let $U = \#\{Y_j > X_i\}$; then we have $W = U + n_2(n_2+1)/2$. Hence an equivalent test for the hypotheses (10.4.4) is to reject H_0 if $U \geq c_2$. It follows immediately from Theorem 10.4.1 that, under H_0 , U is distribution free with mean $n_1 n_2 / 2$ and variance (10.4.10) and that it has an asymptotic normal distribution. The symmetry of the null distribution of either U or W can now be easily obtained. Under H_0 , both X_i and Y_j have the same distribution, so the distributions of U and $U' = \#\{X_i > Y_j\}$ must be the same. Furthermore, $U + U' = n_1 n_2$. This leads to

$$\begin{aligned} P_{H_0} \left(U - \frac{n_1 n_2}{2} = u \right) &= P_{H_0} \left(n_1 n_2 - U' - \frac{n_1 n_2}{2} = u \right) \\ &= P_{H_0} \left(U' - \frac{n_1 n_2}{2} = -u \right) \\ &= P_{H_0} \left(U - \frac{n_1 n_2}{2} = -u \right), \end{aligned}$$

which yields the desired symmetry result in Theorem 10.4.1.

Example 10.4.2 (Water Wheel, Continued). For the R commands to compute the Wilcoxon analysis, suppose y and x contain the respective samples on Y and X . The R call `wilcox.test(y, x)` computes the Wilcoxon test. The form used is the statistic $U = \#\{Y_j > X_i\}$. For the data in Example 10.4.1, let the R vectors `grp1` and `grp2` contain the samples for group 1 and group 2, respectively. Then the call and the results are:

```
wilcox.test(grp2, grp1); W = 61.5, p-value = 0.4053
```

Note that R uses the label `W` for U . As a check, $61.5 + 10(11)/2 = 116.5 = \sum R(y_j)$, which agrees with the computation in Example 10.4.1. The R p -value is exact in the case that there are no ties and if $n_i < 50$, $i = 1, 2$. Otherwise it is based on the asymptotic distribution. Notice that the asymptotic p -value differs a little from its R computed value. The R function `pwilcox(u, n1, n2)` computes the exact cdf of U . ■

Note that if $G(x) = F(x - \Delta)$, then $Y_j - \Delta$ has the same distribution as X_i . So the process of interest here is

$$U(\Delta) = \#\{ (Y_j - \Delta) > X_i \} = \#\{ Y_j - X_i > \Delta \}. \quad (10.4.13)$$

Hence $U(\Delta)$ is counting the number of differences $Y_j - X_i$ that exceed Δ . Let $D_1 < D_2 < \dots < D_{n_1 n_2}$ denote the $n_1 n_2$ ordered differences of $Y_j - X_i$. Then the graph of $U(\Delta)$ is the same as that in Figure 10.2.2, except the D_i 's are on the

horizontal axis and the n on the vertical axis is replaced by $n_1 n_2$; that is, $U(\Delta)$ is a decreasing step function of Δ that steps down one unit at each difference D_i , with the maximum value of $n_1 n_2$.

We can then proceed as in the last two sections to obtain properties of inference based on the Wilcoxon. Let the integer c_α denote the critical value of a level α test of the hypotheses (10.2.2) based on the statistic U ; i.e., $\alpha = P_{H_0}(U \geq c_\alpha)$. Let $\gamma_U(\Delta) = P_\Delta(U \geq c_\alpha)$, for $\Delta \geq 0$, denote the power function of the test. The translation property, Lemma 10.2.1, holds for the process $U(\Delta)$. Hence, as in Theorem 10.2.1, the power function is a nondecreasing function of Δ . In particular, the Wilcoxon test is an unbiased test for the one-sided hypotheses (10.4.4).

10.4.1 Asymptotic Relative Efficiency

The asymptotic relative efficiency (ARE) of the Wilcoxon follows along similar lines as for the sign test statistic in Section 10.2.1. Here, consider the sequence of local alternatives given by

$$H_0 : \Delta = 0 \text{ versus } H_{1n} : \Delta_n = \frac{\delta}{\sqrt{n}}, \quad (10.4.14)$$

where $\delta > 0$. We also assume that

$$\frac{n_1}{n} \rightarrow \lambda_1, \frac{n_2}{n} \rightarrow \lambda_2, \text{ where } \lambda_1 + \lambda_2 = 1. \quad (10.4.15)$$

This assumption implies that $n_1/n_2 \rightarrow \lambda_1/\lambda_2$; i.e, the sample sizes maintain the same ratio asymptotically.

To determine the efficacy of the MWW, consider the average

$$\bar{U}(\Delta) = \frac{1}{n_1 n_2} U(\Delta). \quad (10.4.16)$$

It follows immediately that

$$\mu_{\bar{U}}(0) = E_0(\bar{U}(0)) = \frac{1}{2} \quad \text{and} \quad \bar{\sigma}_{\bar{U}}^2(0) = \frac{n+1}{12n_1 n_2}. \quad (10.4.17)$$

Because the pairs (X_i, Y_j) are iid we have

$$\mu_{\bar{U}}(\Delta_n) = E_{\Delta_n}(\bar{U}(0)) = E_0(\bar{U}(-\Delta_n)) = P_0(Y - X > -\Delta_n). \quad (10.4.18)$$

The independence of X and Y and the fact $\int_{-\infty}^{\infty} F(x)f(x) dx = 1/2$ gives

$$\begin{aligned} P_0(Y - X > -\Delta_n) &= E_0(P_0[Y > X - \Delta_n | X]) \\ &= E_0(1 - F(X - \Delta_n)) \\ &= 1 - \int_{-\infty}^{\infty} F(x - \Delta_n) f(x) dx \\ &= \frac{1}{2} + \int_{-\infty}^{\infty} (F(x) - F(x - \Delta_n)) f(x) dx \\ &\approx \frac{1}{2} + \Delta_n \int_{-\infty}^{\infty} f^2(x) dx, \end{aligned} \quad (10.4.19)$$

where we have applied the mean value theorem to obtain the last line. Putting together (10.4.17) and (10.4.19), we have the efficacy

$$c_U = \lim_{n \rightarrow \infty} \frac{\mu'_U(0)}{\sqrt{n}\sigma_U(0)} = \sqrt{12}\sqrt{\lambda_1\lambda_2} \int_{-\infty}^{\infty} f^2(x) dx. \quad (10.4.20)$$

This derivation can be made rigorous, leading to the following theorem:

Theorem 10.4.2 (Asymptotic Power Lemma). *Consider the sequence of hypotheses (10.4.14). The limit of the power function of the size α Mann–Whitney–Wilcoxon test is given by*

$$\lim_{n \rightarrow \infty} \gamma_U(\Delta_n) = 1 - \Phi\left(z_\alpha - \sqrt{\lambda_1\lambda_2}\delta\tau_W^{-1}\right), \quad (10.4.21)$$

where $\tau_W = 1/\sqrt{12} \int_{-\infty}^{\infty} f^2(x) dx$ is the reciprocal of the efficacy c_U and $\Phi(z)$ is the cdf of a standard normal random variable.

As in the last two sections, we can use this theorem to establish a relative measure of efficiency by considering sample size determination. Consider the hypotheses (10.4.4). Suppose we want to determine the sample size $n = n_1 + n_2$ for a level α MWW test to detect the alternative Δ^* with approximate power γ^* . By Theorem 10.4.2, we have the equation

$$\gamma^* = \gamma_U(\sqrt{n}\Delta^*/\sqrt{n}) \approx 1 - \Phi(z_\alpha - \sqrt{\lambda_1\lambda_2}\sqrt{n}\Delta^*\tau_W^{-1}). \quad (10.4.22)$$

This leads to the equation

$$z_{\gamma^*} = z_\alpha - \sqrt{\lambda_1\lambda_2}\delta\tau_W^{-1}, \quad (10.4.23)$$

where $\Phi(z_{\gamma^*}) = 1 - \gamma^*$. Solving for n , we obtain

$$n_U \approx \left(\frac{(z_\alpha - z_{\gamma^*})\tau_W}{\Delta^*\sqrt{\lambda_1\lambda_2}} \right)^2. \quad (10.4.24)$$

To use this in applications, the sample size proportions $\lambda_1 = n_1/n$ and $\lambda_2 = n_2/n$ must be given. As Exercise 10.4.1 points out, the most powerful two-sample designs have sample size proportions of 1/2, i.e., equal sample sizes.

To use this to obtain the asymptotic relative efficiency between the MWW and the two-sample pooled t -test, Exercise 10.4.2 shows that the sample size needed for the two-sample t -tests to attain approximate power γ^* to detect Δ^* is given by

$$n_{LS} \approx \left(\frac{(z_\alpha - z_{\gamma^*})\sigma}{\Delta^*\sqrt{\lambda_1\lambda_2}} \right)^2, \quad (10.4.25)$$

where σ is the variance of e_i . Hence, as in the last section, the asymptotic relative efficiency between the Wilcoxon test (MWW) and the t -test is the ratio of the sample sizes (10.4.24) and (10.4.25), which is

$$ARE(MWW, LS) = \frac{\sigma^2}{\tau_W^2}. \quad (10.4.26)$$

Note that this is the same ARE as derived in the last section between the signed-rank Wilcoxon and the t -test. If $f(x)$ is a normal pdf, then the MWW has efficiency 95.5% relative to the pooled t -test. Thus the MWW tests lose little efficiency at the normal. On the other hand, it is much more efficient than the pooled t -test at the family of contaminated normals (with $\epsilon > 0$), as in Example 10.3.3.

10.4.2 Estimating Equations Based on the Mann–Whitney–Wilcoxon

As with the signed-rank Wilcoxon procedure in the last section, we invert the test statistic to obtain an estimate of Δ . As discussed in the next section, this estimate can be defined in terms of minimizing a norm. The estimator $\hat{\theta}_W$ solves the estimating equations

$$U(\Delta) = E_{H_0}(U) = \frac{n_1 n_2}{2}. \quad (10.4.27)$$

Recalling the description of the process $U(\Delta)$ described above, it is clear that the Hodges–Lehmann estimator is given by

$$\hat{\Delta}_U = \text{med}_{i,j}\{Y_j - X_i\}. \quad (10.4.28)$$

The asymptotic distribution of the estimate follows in the same way as in the last section based on the process $U(\Delta)$ and the asymptotic power lemma, Theorem 10.4.2. We avoid sketching the proof and simply state the result as a theorem:

Theorem 10.4.3. *Assume that the random variables X_1, X_2, \dots, X_{n_1} are iid with pdf $f(x)$ and that the random variables Y_1, Y_2, \dots, Y_{n_2} are iid with pdf $f(x - \Delta)$. Then*

$$\hat{\Delta}_U \text{ has an approximate } N\left(\Delta, \tau_W^2 \left(\frac{1}{n_1} + \frac{1}{n_2}\right)\right) \text{ distribution,} \quad (10.4.29)$$

where $\tau_W = (\sqrt{12} \int_{-\infty}^{\infty} f^2(x) dx)^{-1}$.

As Exercise 10.4.6 shows, provided the $\text{Var}(\varepsilon_i) = \sigma^2 < \infty$, the LS estimate $\bar{Y} - \bar{X}$ of Δ has the following approximate distribution:

$$\bar{Y} - \bar{X} \text{ has an approximate } N\left(\Delta, \sigma^2 \left(\frac{1}{n_1} + \frac{1}{n_2}\right)\right) \text{ distribution.} \quad (10.4.30)$$

Note that the ratio of the asymptotic variances of $\hat{\Delta}_U$ is given by the ratio (10.4.26). Hence the ARE of the tests agrees with the ARE of the corresponding estimates.

10.4.3 Confidence Interval for the Shift Parameter Δ

The confidence interval for Δ corresponding to the MWW estimate is derived the same way as the Hodges–Lehmann estimate in the last section. For a given level α , let the integer c denote the critical point of the MWW distribution such that $P_\Delta[U(\Delta) \leq c] = \alpha/2$. As in Section 10.2.3, we then have

$$\begin{aligned} 1 - \alpha &= P_\Delta[c < U(\Delta) < n_1 n_2 - c] \\ &= P_\Delta[D_{c+1} \leq \Delta < D_{n_1 n_2 - c}], \end{aligned} \quad (10.4.31)$$

where $D_1 < D_2 < \dots < D_{n_1 n_2}$ denote the order differences $Y_j - X_i$. Therefore, the interval $[D_{c+1}, D_{n_1 n_2 - c}]$ is a $(1 - \alpha)100\%$ confidence interval for Δ . Using the null asymptotic distribution of the MWW test statistic U , we have the following approximation for c :

$$c \approx \frac{n_1 n_2}{2} - z_{\alpha/2} \sqrt{\frac{n_1 n_2 (n + 1)}{12}} - \frac{1}{2}, \quad (10.4.32)$$

where $\Phi(-z_{\alpha/2}) = \alpha/2$; see Exercise 10.4.7. In practice, we use the closest integer to c .

Example 10.4.3 (Example 10.4.1, Continued). Returning to Example 10.4.1, the computation in R (groups are in the vectors `grp1` and `grp2`) yields:

```
wilcox.test(grp2, grp1, conf.int=T)
95 percent confidence interval: -0.8000273 2.8999445
sample estimate: 0.5000127
```

Hence, the Hodges–Lehmann estimate of the shift in locations is 0.50 and the confidence interval for the shift is $(-0.800, 2.890)$. Hence, in agreement with the test statistic, the confidence interval covers the null hypothesis of $\Delta = 0$. ■

10.4.4 Monte Carlo Investigation of Power

In Section 10.3.4, we discussed a Monte Carlo investigation of the finite sample size relative efficiency between two location estimators. In this section, we consider finite sample studies of the power of two tests. As in Section 10.3.4, a Monte Carlo study comparing the power of two tests would be over specified families of distributions and sample sizes, each combination of which is a situation of the study. For our brief presentation, we consider one such situation.

The model is the two-sample location model described by (10.4.2)–(10.4.3) where Δ is the shift in location between the models. We consider the two-sided hypotheses

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta \neq 0. \quad (10.4.33)$$

Our study compares the power of the MWW and two-sample t -test, as defined in Example 8.3.1, for these hypotheses. For our specific situation we consider equal sample sizes $n_1 = n_2 = 30$ and the contaminated normal distribution with contamination rate $\epsilon = 0.20$ and standard deviation ratio $\sigma_c = 10$. As the level of significance, we select $\alpha = 0.05$. Notice that for a given data set, a level α test rejects H_0 if its p -value is less than or equal to α .

We chose 10,000 simulations. The gist of the algorithm is straightforward. For each simulation, generate the independent samples; compute each test statistic; and record whether or not each test rejected. For each test, its empirical power is its number of rejections divided by the number of simulations. The following R function `wil2powsim.R` incorporates this algorithm. The first line of code contains the settings that were used.

```
n1=30;n2=30;nsims=10000;eps=.20;vc=10;Delta=seq(-3,3,1) #Settings
wil2powsim <- function(n1,n2,nsims,eps,vc,Delta=0,alpha=.05){
```

```

indwil <-0; indt <- 0
for(i in 1:nsims){
  x <- rcn(n1,eps,vc); y <- rcn(n2,eps,vc) + Delta
  if(wilcox.test(y,x)$p.value <= alpha){indwil <- indwil + 1}
  if(t.test(y,x,var.equal=T)$p.value <= alpha){indt <- indt + 1}
}
powwil <- sum(indwil)/nsims; powt <- sum(indt)/nsims
return(c(powwil,powt))

```

Notice that power is computed at the sequence of alternatives $\Delta = -3, -2, \dots, 3$. For our run, here are the empirical powers:

Δ	-3	-2	-1	0	1	2	3
MWW test	0.9993	0.9856	0.6859	0.0527	0.6889	0.9874	0.9988
<i>t</i> -test	0.7245	0.4411	0.1575	0.0465	0.1597	0.4318	0.7296

Clearly for this situation the MWW test is much more powerful than the *t*-test. It is not surprising since the contaminated normal distribution has heavy tails and the *t*-test is impaired by the high percentage of outliers. Further, this agrees with the ARE between the MWW and *t*-tests for contaminated normal distributions. The empirical powers for $\Delta = 0$ are the empirical levels that are close to the nominal $\alpha = 0.05$. For both tests, the powers increase as Δ moves in either direction from 0, as they should.

EXERCISES

10.4.1. By considering the asymptotic power lemma, Theorem 10.4.2, show that the equal sample size situation $n_1 = n_2$ is the most powerful design among designs with $n_1 + n_2 = n$, n fixed, when level and alternatives are also fixed.

Hint: Show that this problem is equivalent to maximizing the function

$$g(n_1) = \frac{n_1(n - n_1)}{n^2},$$

and then obtain the result.

10.4.2. Consider the asymptotic version of the *t*-test for the hypotheses (10.4.4) which is discussed in Example 4.6.2.

- (a) Using the setup of Theorem 10.4.2, derive the corresponding asymptotic power lemma for this test.
- (b) Use your result in part (a) to obtain expression (10.4.25).

10.4.3. In the power study presented in Section 10.4.4, the empirical powers at $\Delta = 0$ are empirical levels. Find 95% confidence intervals for the true levels based on the empirical levels. Do they contain the nominal level $\alpha = 0.05$?

10.4.4. In the power study of Section 10.4.4, determine (by simulation) the necessary common sample size so that the Wilcoxon MWW test has approximately 80% power to detect $\Delta = 1$.

10.4.5. For the power study of Section 10.4.4, modify the R function `wil2powsim.R` to obtain the empirical powers for the $N(0, 1)$ distribution.

10.4.6. Use the Central Limit Theorem to show that expression (10.4.30) is true.

10.4.7. For the cutoff index c of the confidence interval (10.4.31) for Δ , derive the approximation given in expression (10.4.32).

10.4.8. Let X be a continuous random variable with cdf $F(x)$. Suppose $Y = X + \Delta$, where $\Delta > 0$. Show that Y is stochastically larger than X .

10.4.9. Consider the data given in Example 10.4.1.

- (a) Obtain comparison boxplots of the data.
- (b) Show that the difference in sample means is 3.11, which is much larger than the MWW estimate of shift. What accounts for this discrepancy?
- (c) Show that the 95% confidence interval for Δ using t is given by $(-2.7, 8.92)$. Why is this interval so much larger than the corresponding MWW interval?
- (d) Show that the value of the t -test statistic, discussed in Example 4.6.2, for this data set is 1.12 with p -value 0.28. Although, as with the MWW results, this p -value would be considered insignificant, it seems lower than warranted [consider, for example, the comparison boxplots of part (a)]. Why?

10.5 *General Rank Scores

Suppose we are interested in estimating the center of a symmetric distribution using an estimator that corresponds to a distribution-free procedure. By the last two sections our choice is either the sign test or the signed-rank Wilcoxon test. If the sample is drawn from a normal distribution, then of the two we would choose the signed-rank Wilcoxon because it is much more efficient than the sign test at the normal distribution. But the Wilcoxon is not fully efficient. This raises the question: Is there a distribution-free procedure that is fully efficient at the normal distribution, i.e., has efficiency of 100% relative to the t -test at the normal? More generally, suppose we specify a distribution. Is there a distribution-free procedure that has 100% efficiency relative to the mle at that distribution? In general, the answer to both of these questions is yes. In this section, we explore these questions for the two-sample location problem since this problem generalizes immediately to the regression problem of Section 10.7. A similar theory can be developed for the one-sample problem; see Chapter 1 of Hettmansperger and McKean (2011).

As in the last section, let X_1, X_2, \dots, X_{n_1} be a random sample from the continuous distribution with cdf and pdf $F(x)$ and $f(x)$, respectively. Let Y_1, Y_2, \dots, Y_{n_2} be a random sample from the continuous distribution with cdf and pdf, respectively, $F(x - \Delta)$ and $f(x - \Delta)$, where Δ is the shift in location. Let $n = n_1 + n_2$ denote the combined sample sizes. Consider the hypotheses

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0. \quad (10.5.1)$$

We first define a general class of rank scores. Let $\varphi(u)$ be a nondecreasing function defined on the interval $(0, 1)$, such that $\int_0^1 \varphi^2(u) du < \infty$. We call $\varphi(u)$ a **score** function. Without loss of generality, we standardize this function so that $\int_0^1 \varphi(u) du = 0$ and $\int_0^1 \varphi^2(u) du = 1$; see Exercise 10.5.1. Next, define the scores $a_\varphi(i) = \varphi[i/(n+1)]$, for $i = 1, \dots, n$. Then $a_\varphi(1) \leq a_\varphi(2) \leq \dots \leq a_\varphi(n)$. Assume that $\sum_{i=1}^n a_\varphi(i) = 0$, (this essentially follows from $\int \varphi(u) du = 0$, see Exercise 10.5.12). Consider the test statistic

$$W_\varphi = \sum_{j=1}^{n_2} a_\varphi(R(Y_j)), \quad (10.5.2)$$

where $R(Y_j)$ denotes the rank of Y_j in the combined sample of n observations. Since the scores are nondecreasing, a natural rejection rule is given by

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } W_\varphi \geq c. \quad (10.5.3)$$

Note that if we use the linear score function $\varphi(u) = \sqrt{12}(u - (1/2))$, then

$$\begin{aligned} W_\varphi &= \sum_{j=1}^{n_2} \sqrt{12} \left(\frac{R(Y_j)}{n+1} - \frac{1}{2} \right) = \frac{\sqrt{12}}{n+1} \sum_{j=1}^{n_2} \left(R(Y_j) - \frac{n+1}{2} \right) \\ &= \frac{\sqrt{12}}{n+1} W - \frac{\sqrt{12}n_2}{2}, \end{aligned} \quad (10.5.4)$$

where W is the MWU test statistic, (10.4.5). Hence the special case of a linear score function results in the MWU test statistic.

To complete the decision rule (10.5.2), we need the null distribution of the test statistic W_φ . But many of its properties follow along the same lines as that of the MWU test. First, W_φ is distribution free because, under the null hypothesis, every subset of ranks for the Y_j s is equilike. In general, the distribution of W_φ cannot be obtained in closed form, but it can be generated recursively similarly to the distribution of the MWU test statistic. Next, to obtain the null mean of W_φ , use the fact that $R(Y_j)$ is uniform on the integers $1, 2, \dots, n$. Because $\sum_{i=1}^n a_\varphi(i) = 0$, we then have

$$E_{H_0}(W_\varphi) = \sum_{j=1}^{n_2} E_{H_0}(a_\varphi(R(Y_j))) = \sum_{j=1}^{n_2} \sum_{i=1}^n a_\varphi(i) \frac{1}{n} = 0. \quad (10.5.5)$$

To determine the null variance, first define the quantity s_a^2 by the equation

$$E_{H_0}(a_\varphi^2(R(Y_j))) = \sum_{i=1}^n a_\varphi^2(i) \frac{1}{n} = \frac{1}{n} \sum_{i=1}^n a_\varphi^2(i) = \frac{1}{n} s_a^2. \quad (10.5.6)$$

As Exercise 10.5.4 shows, $s_a^2/n \approx 1$. Since $E_{H_0}(W_\varphi) = 0$, we have

$$\begin{aligned}\text{Var}_{H_0}(W_\varphi) &= E_{H_0}(W_\varphi^2) = \sum_{j=1}^{n_2} \sum_{j'=1}^{n_2} E_{H_0}[a_\varphi(R(Y_j))a_\varphi(R(Y_{j'}))] \\ &= \sum_{j=1}^{n_2} E_{H_0}[a_\varphi^2(R(Y_j))] + \sum_{j \neq j'} E_{H_0}[a_\varphi(R(Y_j))a_\varphi(R(Y_{j'}))] \\ &= \frac{n_2}{n} s_a^2 - \frac{n_2(n_2-1)}{n(n-1)} s_a^2 \quad (10.5.7)\end{aligned}$$

$$= \frac{n_1 n_2}{n(n-1)} s_a^2; \quad (10.5.8)$$

see Exercise 10.5.2 for the derivation of the second term in expression (10.5.7). In more advanced books, it is shown that W_φ is asymptotically normal under H_0 . Hence the corresponding asymptotic decision rule of level α is

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } z = \frac{W_\varphi}{\sqrt{\text{Var}_{H_0}(W_\varphi)}} \geq z_\alpha. \quad (10.5.9)$$

To answer the questions posed in the first paragraph of this section, the efficacy of the test statistic W_φ is needed. To proceed along the lines of the last section, define the process

$$W_\varphi(\Delta) = \sum_{j=1}^{n_2} a_\varphi(R(Y_j - \Delta)), \quad (10.5.10)$$

where $R(Y_j - \Delta)$ denotes the rank of $Y_j - \Delta$ among $X_1, \dots, X_{n_1}, Y_1 - \Delta, \dots, Y_{n_2} - \Delta$. In the last section, the process for the MWW statistic was also written in terms of counts of the differences $Y_j - X_i$. We are not as fortunate here, but as the next theorem shows, this general process is a simple decreasing step function of Δ .

Theorem 10.5.1. *The process $W_\varphi(\Delta)$ is a decreasing step function of Δ which steps down at each difference $Y_j - X_i$, $i = 1, \dots, n_1$ and $j = 1, \dots, n_2$. Its maximum and minimum values are $\sum_{j=n_1+1}^n a_\varphi(j) \geq 0$ and $\sum_{j=1}^{n_2} a_\varphi(j) \leq 0$, respectively.*

Proof: Suppose $\Delta_1 < \Delta_2$ and $W_\varphi(\Delta_1) \neq W_\varphi(\Delta_2)$. Hence the assignment of the ranks among the X_i and $Y_j - \Delta$ must differ at Δ_1 and Δ_2 ; that is, then there must be a j and an i such that $Y_j - \Delta_2 < X_i$ and $Y_j - \Delta_1 > X_i$. This implies that $\Delta_1 < Y_j - X_i < \Delta_2$. Thus $W_\varphi(\Delta)$ changes values at the differences $Y_j - X_i$. To show it is decreasing, suppose $\Delta_1 < Y_j - X_i < \Delta_2$ and there are no other differences between Δ_1 and Δ_2 . Then $Y_j - \Delta_1$ and X_i must have adjacent ranks; otherwise, there would be more than one difference between Δ_1 and Δ_2 . Since $Y_j - \Delta_1 > X_i$ and $Y_j - \Delta_2 < X_i$, we have

$$R(Y_j - \Delta_1) = R(X_i) + 1 \text{ and } R(Y_j - \Delta_2) = R(X_i) - 1.$$

Also, in the expression for $W_\varphi(\Delta)$, only the rank of the Y_j term has changed in the

interval $[\Delta_1, \Delta_2]$. Therefore, since the scores are nondecreasing,

$$\begin{aligned} W_\varphi(\Delta_1) - W_\varphi(\Delta_2) &= \sum_{k \neq j} a_\varphi(R(Y_k - \Delta_1)) + a_\varphi(R(Y_j - \Delta_1)) \\ &\quad - \left[\sum_{k \neq j} a_\varphi(R(Y_k - \Delta_2)) + a_\varphi(R(Y_j - \Delta_2)) \right] \\ &= a_\varphi(R(X_i) + 1)) - a_\varphi(R(X_i) - 1)) \geq 0. \end{aligned}$$

Because $W_\varphi(\Delta)$ is a decreasing step function and steps only at the differences $Y_j - X_i$, its maximum value occurs when $\Delta < Y_j - X_i$, for all i, j , i.e., when $X_i < Y_j - \Delta$, for all i, j . Hence, in this case, the variables $Y_j - \Delta$ must get all the high ranks, so

$$\max_{\Delta} W_\varphi(\Delta) = \sum_{j=n_1+1}^n a_\varphi(j).$$

Note that this maximum value must be nonnegative. For suppose it was strictly negative, then at least one $a_\varphi(j) < 0$ for $j = n_1 + 1, \dots, n$. Because the scores are nondecreasing, $a_\varphi(i) < 0$ for all $i = 1, \dots, n_1$. This leads to the contradiction

$$0 > \sum_{j=n_1+1}^n a_\varphi(j) \geq \sum_{j=n_1+1}^n a_\varphi(j) + \sum_{j=1}^{n_1} a_\varphi(j) = 0.$$

The results for the minimum value are obtained in the same way; see Exercise 10.5.6.

■

As Exercise 10.5.7 shows, the translation property, Lemma 10.2.1, holds for the process $W_\varphi(\Delta)$. Using this result and the last theorem, we can show that the power function of the test statistic W_φ for the hypotheses (10.5.1) is nondecreasing. Hence the test is unbiased.

10.5.1 Efficacy

We next sketch the derivation of the efficacy of the test based on W_φ . Our arguments can be made rigorous; see advanced texts. Consider the statistic given by the average

$$\overline{W}_\varphi(0) = \frac{1}{n} W_\varphi(0). \quad (10.5.11)$$

Based on (10.5.5) and (10.5.8), we have

$$\mu_\varphi(0) = E_0(\overline{W}_\varphi(0)) = 0 \quad \text{and} \quad \sigma_\varphi^2 = \text{Var}_0(\overline{W}_\varphi(0)) = \frac{n_1 n_2}{n(n-1)} n^{-2} s_a^2. \quad (10.5.12)$$

Notice from Exercise 10.5.4 that the variance of $\overline{W}_\varphi(0)$ is of the order $O(n^{-2})$. We have

$$\mu_\varphi(\Delta) = E_\Delta[\overline{W}_\varphi(0)] = E_0[\overline{W}_\varphi(-\Delta)] = \frac{1}{n} \sum_{j=1}^{n_2} E_0[a_\varphi(R(Y_j + \Delta))]. \quad (10.5.13)$$

Suppose that \widehat{F}_{n_1} and \widehat{F}_{n_2} are the empirical cdfs of the random samples X_1, \dots, X_{n_1} and Y_1, \dots, Y_{n_2} , respectively. The relationship between the ranks and empirical cdfs follows as

$$\begin{aligned} R(Y_j + \Delta) &= \#\{Y_k + \Delta \leq Y_j + \Delta\} + \#\{X_i \leq Y_j + \Delta\} \\ &= \#\{Y_k \leq Y_j\} + \#\{X_i \leq Y_j + \Delta\} \\ &= n_2 \widehat{F}_{n_2}(Y_j) + n_1 \widehat{F}_{n_1}(Y_j + \Delta). \end{aligned} \quad (10.5.14)$$

Substituting this last expression into expression (10.5.13), we get

$$\mu_\varphi(\Delta) = \frac{1}{n} \sum_{j=1}^{n_2} E_0 \left\{ \varphi \left[\frac{n_2}{n+1} \widehat{F}_{n_2}(Y_j) + \frac{n_1}{n+1} \widehat{F}_{n_1}(Y_j + \Delta) \right] \right\} \quad (10.5.15)$$

$$\rightarrow \lambda_2 E_0 \{ \varphi [\lambda_2 F(Y) + \lambda_1 F(Y + \Delta)] \} \quad (10.5.16)$$

$$= \lambda_2 \int_{-\infty}^{\infty} \varphi [\lambda_2 F(y) + \lambda_1 F(y + \Delta)] f(y) dy. \quad (10.5.17)$$

The limit in expression (10.5.16) is actually a double limit, which follows from $\widehat{F}_{n_i}(x) \rightarrow F(x)$, $i = 1, 2$, under H_0 , and the observation that upon substituting F for the empirical cdfs in expression (10.5.15), the sum contains identically distributed random variables and, thus, the same expectation. These approximations can be made rigorous. It follows immediately that

$$\frac{d}{d\Delta} \mu_\varphi(\Delta) = \lambda_2 \int_{-\infty}^{\infty} \varphi' [\lambda_2 F(Y) + \lambda_1 F(Y + \Delta)] \lambda_1 f(y + \Delta) f(y) dy.$$

Hence

$$\mu'_\varphi(0) = \lambda_1 \lambda_2 \int_{-\infty}^{\infty} \varphi' [F(y)] f^2(y) dy. \quad (10.5.18)$$

From (10.5.12),

$$\sqrt{n} \sigma_\varphi = \sqrt{n} \sqrt{\frac{n_1 n_2}{n(n-1)}} \frac{1}{\sqrt{n}} \sqrt{\frac{1}{n} s_a^2} \rightarrow \sqrt{\lambda_1 \lambda_2}. \quad (10.5.19)$$

Based on (10.5.18) and (10.5.19), the efficacy of W_φ is given by

$$c_\varphi = \lim_{n \rightarrow \infty} \frac{\mu'_\varphi(0)}{\sqrt{n} \sigma_\varphi} = \sqrt{\lambda_1 \lambda_2} \int_{-\infty}^{\infty} \varphi' [F(y)] f^2(y) dy. \quad (10.5.20)$$

Using the efficacy, the asymptotic power can be derived for the test statistic W_φ . Consider the sequence of local alternatives given by (10.4.14) and the level α asymptotic test based on W_φ . Denote the power function of the test by $\gamma_\varphi(\Delta_n)$. Then it can be shown that

$$\lim_{n \rightarrow \infty} \gamma_\varphi(\Delta_n) = 1 - \Phi(z_\alpha - c_\varphi \delta), \quad (10.5.21)$$

where $\Phi(z)$ is the cdf of a standard normal random variable. Sample size determination based on the test statistic W_φ proceeds as in the last few sections; see Exercise 10.5.8.

10.5.2 Estimating Equations Based on General Scores

Suppose we are using the scores $a_\varphi(i) = \varphi(i/(n+1))$ discussed in Section 10.5.1. Recall that the mean of the test statistic W_φ is 0. Hence the corresponding estimator of Δ solves the estimating equations

$$W_\varphi(\hat{\Delta}) \approx 0. \quad (10.5.22)$$

By Theorem 10.5.1, $W_\varphi(\hat{\Delta})$ is a decreasing step function of Δ . Furthermore, the maximum value is positive and the minimum value is negative (only degenerate cases would result in one or both of these as 0); hence, the solution to equation (10.5.22) exists. Because $W_\varphi(\hat{\Delta})$ is a step function, it may not be unique. When it is not unique, though, as with Wilcoxon and median procedures, there is an interval of solutions, so the midpoint of the interval can be chosen. This is an easy equation to solve numerically because simple iterative techniques such as the bisection method or the method of false position can be used; see the discussion on page 210 of Hettmansperger and McKean (2011). The asymptotic distribution of the estimator can be derived using the asymptotic power lemma and is given by

$$\hat{\Delta}_\varphi \text{ has an approximate } N\left(\Delta, \tau_\varphi^2 \left(\frac{1}{n_1} + \frac{1}{n_2}\right)\right) \text{ distribution,} \quad (10.5.23)$$

where

$$\tau_\varphi = \left[\int_{-\infty}^{\infty} \varphi'[F(y)] f^2(y) dy \right]^{-1}. \quad (10.5.24)$$

Hence the efficacy can be expressed as $c_\varphi = \sqrt{\lambda_1 \lambda_2} \tau_\varphi^{-1}$. As Exercise 10.5.9 shows, the parameter τ_φ is a scale parameter. Since the efficacy is $c_\varphi = \sqrt{\lambda_1 \lambda_2} \tau_\varphi^{-1}$, the efficacy varies inversely with scale. This observation proves helpful in the next subsection.

10.5.3 Optimization: Best Estimates

We can now answer the questions posed in the first paragraph. For a given pdf $f(x)$, we show that in general we can select a score function that maximizes the power of the test and minimizes the asymptotic variance of the estimator. Under certain conditions we show that estimators based on this optimal score function have the same efficiency as maximum likelihood estimators (mles); i.e., they obtain the Rao–Cramér Lower Bound.

As above, let X_1, \dots, X_{n_1} be a random sample from the continuous cdf $F(x)$ with pdf $f(x)$. Let Y_1, \dots, Y_{n_2} be a random sample from the continuous cdf $F(x - \Delta)$ with pdf $f(x - \Delta)$. The problem is to choose φ to maximize the efficacy c_φ given in expression (10.5.20). Note that maximizing the efficacy is equivalent to minimizing the asymptotic variance of the corresponding estimator of Δ .

For a general score function $\varphi(u)$, consider its efficacy given by expression (10.5.20). Without loss of generality, the relative sample sizes in this expression

can be ignored, so we consider $c_\varphi^* = (\sqrt{\lambda_1 \lambda_2})^{-1} c_\varphi$. If we make the change of variables $u = F(y)$ and then integrate by parts, we get

$$\begin{aligned} c_\varphi^* &= \int_{-\infty}^{\infty} \varphi'[F(y)] f^2(y) dy \\ &= \int_0^1 \varphi'(u) f(F^{-1}(u)) du \\ &= \int_0^1 \varphi(u) \left[-\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right] du. \end{aligned} \quad (10.5.25)$$

Recall that the score function $\int \varphi^2(u) du = 1$. Thus we can state the problem as

$$\begin{aligned} \max_{\varphi} c_\varphi^{*2} &= \max_{\varphi} \left\{ \int_0^1 \varphi(u) \left[-\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right] du \right\}^2 \\ &= \left\{ \max_{\varphi} \frac{\left\{ \int_0^1 \varphi(u) \left[-\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right] du \right\}^2}{\int_0^1 \varphi^2(u) du \int_0^1 \left[\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right]^2 du} \right\} \int_0^1 \left[\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right]^2 du. \end{aligned}$$

The quantity that we are maximizing in the braces of this last expression, however, is the square of a correlation coefficient, which achieves its maximum value 1. Therefore, by choosing the score function $\varphi(u) = \varphi_f(u)$, where

$$\varphi_f(u) = -\kappa \frac{f'(F^{-1}(u))}{f(F^{-1}(u))}, \quad (10.5.26)$$

and κ is a constant chosen so that $\int \varphi_f^2(u) du = 1$, then the correlation coefficient is 1 and the maximum value is

$$I(f) = \int_0^1 \left[\frac{f'(F^{-1}(u))}{f(F^{-1}(u))} \right]^2 du, \quad (10.5.27)$$

which is Fisher information for the location model. We call the score function given by (10.5.26) the **optimal score function**.

In terms of estimation, if $\hat{\Delta}$ is the corresponding estimator, then, according to (10.5.24), it has the asymptotic variance

$$\tau_\varphi^2 = \left[\frac{1}{I(f)} \right] \left(\frac{1}{n_1} + \frac{1}{n_2} \right). \quad (10.5.28)$$

Thus the estimator $\hat{\Delta}$ achieves asymptotically the Rao–Cramér lower bound; that is, $\hat{\Delta}$ is an asymptotically efficient estimator of Δ . In terms of asymptotic relative efficiency, the ARE between the estimator $\hat{\Delta}$ and the mle of Δ is 1. Thus we have answered the second question of the first paragraph of this section.

Now we look at some examples. The initial example assumes that the distribution of ε_i is normal, which answers the leading question at the beginning of this

section. First, though, note an invariance that simplifies matters. Suppose Z is a scale and location transformation of a random variable X ; i.e., $Z = a(X - b)$, where $a > 0$ and $-\infty < b < \infty$. Because the efficacy varies indirectly with scale, we have $c_{f_Z}^2 = a^{-2}c_{f_X}^2$. Furthermore, as Exercise 10.5.9 shows, the efficacy is invariant to location and, also, $I(f_Z) = a^{-2}I(f_X)$. Hence the quantity maximized above is invariant to changes in location and scale. In particular, in the derivation of optimal scores, only the form of the density is important.

Example 10.5.1 (Normal Scores). Suppose the error random variable ε_i has a normal distribution. Based on the discussion in the last paragraph, we can take the pdf of a $N(0, 1)$ distribution as the form of the density. So consider $f_Z(z) = \phi(z) = (2\pi)^{-1/2} \exp\{-z^2/2\}$. Then $-\phi'(z) = z\phi(z)$. Let $\Phi(z)$ denote the cdf of Z . Hence the optimal score function is

$$\varphi_N(u) = -\kappa \frac{\phi'(\Phi^{-1}(u))}{\phi(\Phi^{-1}(u))} = \Phi^{-1}(u); \quad (10.5.29)$$

see Exercise 10.5.5, which shows that $\kappa = 1$ as well as that $\int \varphi_N(u) du = 0$. The corresponding scores, $a_N(i) = \Phi^{-1}(i/(n+1))$, are often called the **normal scores**. Denote the process by

$$W_N(\Delta) = \sum_{j=1}^{n_2} \Phi^{-1}[R(Y_j - \Delta)/(n+1)]. \quad (10.5.30)$$

The associated test statistic for the hypotheses (10.5.1) is the statistic $W_N = W_N(0)$. The estimator of Δ solves the estimating equations

$$W_N(\hat{\Delta}_N) \approx 0. \quad (10.5.31)$$

Although the estimate cannot be obtained in closed form, this equation is relatively easy to solve numerically. From the above discussion, $\text{ARE}(\hat{\Delta}_N, \bar{Y} - \bar{X}) = 1$ at the normal distribution. Hence normal score procedures are fully efficient at the normal distribution. Actually, a much more powerful result can be obtained for symmetric distributions. It can be shown that $\text{ARE}(\hat{\Delta}_N, \bar{Y} - \bar{X}) \geq 1$ at all symmetric distributions. ■

Example 10.5.2 (Wilcoxon Scores). Suppose the random errors, ε_i , $i = 1, 2, \dots, n$, have a logistic distribution with pdf $f_Z(z) = \exp\{-z\}/(1 + \exp\{-z\})^2$. Then the corresponding cdf is $F_Z(z) = (1 + \exp\{-z\})^{-1}$. As Exercise 10.5.11 shows,

$$-\frac{f'_Z(z)}{f_Z(z)} = F_Z(z)(1 - \exp\{-z\}) \quad \text{and} \quad F_Z^{-1}(u) = \log \frac{u}{1-u}. \quad (10.5.32)$$

Upon standardization, this leads to the optimal score function,

$$\varphi_W(u) = \sqrt{12}(u - (1/2)), \quad (10.5.33)$$

that is, the Wilcoxon scores. The properties of the inference based on Wilcoxon scores are discussed in Section 10.4. Let $\hat{\Delta}_W = \text{med}\{Y_j - X_i\}$ denote the corresponding estimate. Recall that $\text{ARE}(\hat{\Delta}_W, \bar{Y} - \bar{X}) = 0.955$ at the normal. Hodges and Lehmann (1956) showed that $\text{ARE}(\hat{\Delta}_W, \bar{Y} - \bar{X}) \geq 0.864$ over all symmetric distributions. ■

Table 10.5.1: Data for Example 10.5.3

Data	Sample 1 (X)		Data	Sample 2 (Y)	
	Ranks	Normal Scores		Ranks	Normal Scores
51.9	15	-0.04044	59.2	24	0.75273
56.9	23	0.64932	49.1	14	-0.12159
45.2	11	-0.37229	54.4	19	0.28689
52.3	16	0.04044	47.0	13	-0.20354
59.5	26	0.98917	55.9	21	0.46049
41.4	4	-1.13098	34.9	3	-1.30015
46.4	12	-0.28689	62.2	28	1.30015
45.1	10	-0.46049	41.6	6	-0.86489
53.9	17	0.12159	59.3	25	0.86489
42.9	7	-0.75273	32.7	1	-1.84860
41.5	5	-0.98917	72.1	29	1.51793
55.2	20	0.37229	43.8	8	-0.64932
32.9	2	-1.51793	56.8	22	0.55244
54.0	18	0.20354	76.7	30	1.84860
45.0	9	-0.55244	60.3	27	1.13098

Example 10.5.3. As a numerical illustration, we consider some generated normal observations. The first sample, labeled X , was generated from a $N(48, 10^2)$ distribution, while the second sample, Y , was generated from a $N(58, 10^2)$ distribution. The data are displayed in Table 10.5.1, but they can also be found in the file `examp1053.rda`. Also in Table 10.5.1, the ranks and the normal scores are exhibited. We consider tests of the two-sided hypotheses $H_0 : \Delta = 0$ versus $H_1 : \Delta \neq 0$ for the Wilcoxon, normal scores, and Student t procedures. The next segment of R code returns the results in Table 10.5.2. As we have used the R functions `t.test` and `wilcox.test` in the last section we do not show their results in the segment but we do show the results for the normal scores. The code assumes that the R vectors x and y contain the respective samples.

```
t.test(y,x); wilcox.test(y,x,conf.int=T)
zed=c(x,y); ind=c(rep(0,15),rep(1,15)); rz=rank(z)
phis=qnorm(rz/31); varns= ((15*15)/(30*29))*sum(phis^2)
nstst=sum(ind*phis); stdns=nstst/sqrt(varns)
pns =2*(1-pnorm(abs(stdns)))
nstst; stdns; pns
3.727011; 1.483559; 0.137926
```

To complete the summary in Table 10.5.2 we need the estimate of Δ based on the rank-based normal scores process. Kloke and McKean (2014) discuss the use of the CRAN package `Rfit` for this computation. If this package is installed in the users area then the following command computes this estimate of Δ :

```
rfit(zed~ind,scores=nscores)$coef[2]
5.100012
```

Table 10.5.2: Summary of analyses for Example 10.5.3

Method	Test Statistic	Standardized	<i>p</i> -Value	Estimate of Δ
Student <i>t</i>	$\bar{Y} - \bar{X} = 5.46$	1.47	0.16	5.46
Wilcoxon	$W = 270$	1.53	0.12	5.20
Normal scores	$W_N = 3.73$	1.48	0.14	5.15

Notice that the standardized tests statistics and their corresponding *p*-values are quite similar and all would result in the same decision regarding the hypotheses. As shown in the table, the corresponding point estimates of Δ are also alike.

We changed x_5 to be an outlier with value 95.5 and then reran the analyses. The *t*-analysis was the most affected, for on the changed data, $t = 0.63$ with a *p*-value of 0.53. In contrast, the Wilcoxon analysis was the least affected ($z = 1.37$ and $p = 0.17$). The normal scores analysis was more affected by the outlier than the Wilcoxon analysis with $z = 1.14$ and $p = 0.25$. ■

Example 10.5.4 (Sign Scores). For our final example, suppose that the random errors $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ have a Laplace distribution. Consider the convenient form $f_Z(z) = 2^{-1} \exp\{-|z|\}$. Then $f'_Z(z) = -2^{-1} \text{sgn}(z) \exp\{-|z|\}$ and, hence, $-f'_Z(F_Z^{-1}(u))/f_Z(F_Z^{-1}(u)) = \text{sgn}(z)$. But $F_Z^{-1}(u) > 0$ if and only if $u > 1/2$. The optimal score function is

$$\varphi_S(u) = \text{sgn}\left(u - \frac{1}{2}\right), \quad (10.5.34)$$

which is easily shown to be standardized. The corresponding process is

$$W_S(\Delta) = \sum_{j=1}^{n_2} \text{sgn}\left[R(Y_j - \Delta) - \frac{n+1}{2}\right]. \quad (10.5.35)$$

Because of the signs, this test statistic can be written in a simpler form, which is often called **Mood's** test; see Exercise 10.5.13.

We can also obtain the associated estimator in closed form. The estimator solves the equation

$$\sum_{j=1}^{n_2} \text{sgn}\left[R(Y_j - \Delta) - \frac{n+1}{2}\right] = 0. \quad (10.5.36)$$

For this equation, we rank the variables

$$\{X_1, \dots, X_{n_1}, Y_1 - \Delta, \dots, Y_{n_2} - \Delta\}.$$

Because ranks, though, are invariant to a constant shift, we obtain the same ranks if we rank the variables

$$X_1 - \text{med}\{X_i\}, \dots, X_{n_1} - \text{med}\{X_i\}, Y_1 - \Delta - \text{med}\{X_i\}, \dots, Y_{n_2} - \Delta - \text{med}\{X_i\}.$$

Therefore, the solution to equation (10.5.36) is easily seen to be

$$\hat{\Delta}_S = \text{med}\{Y_j\} - \text{med}\{X_i\}. \quad ■ \quad (10.5.37)$$

Other examples are given in the exercises.

EXERCISES

10.5.1. In this section, as discussed above expression (10.5.2), the scores $a_\varphi(i)$ are generated by the standardized score function $\varphi(u)$; that is, $\int_0^1 \varphi(u) du = 0$ and $\int_0^1 \varphi^2(u) du = 1$. Suppose that $\psi(u)$ is a square-integrable function defined on the interval $(0, 1)$. Consider the score function defined by

$$\varphi(u) = \frac{\psi(u) - \bar{\psi}}{\int_0^1 [\psi(v) - \bar{\psi}]^2 dv},$$

where $\bar{\psi} = \int_0^1 \psi(v) dv$. Show that $\varphi(u)$ is a standardized score function.

10.5.2. Complete the derivation of the null variance of the test statistic W_φ by showing the second term in expression (10.5.7) is true.

Hint: Use the fact that under H_0 , for $j \neq j'$, the pair $(a_\varphi(R(Y_j)), a_\varphi(R(Y_{j'})))$ is uniformly distributed on the pairs of integers (i, i') , $i, i' = 1, 2, \dots, n$, $i \neq i'$.

10.5.3. For the Wilcoxon score function $\varphi(u) = \sqrt{12}[u - (1/2)]$, obtain the value of s_a . Then show that the $V_{H_0}(W_\varphi)$ given in expression (10.5.8) is the same (except for standardization) as the variance of the MWV statistic of Section 10.4.

10.5.4. Recall that the scores have been standardized so that $\int_{-\infty}^{\infty} \varphi^2(u) du = 1$. Use this and a Riemann sum to show that $n^{-1}s_a^2 \rightarrow 1$, where s_a^2 is defined in expression (10.5.6).

10.5.5. Show that the normal scores, (10.5.29), derived in Example 10.5.1 are standardized; that is, $\int_0^1 \varphi_N(u) du = 0$ and $\int_0^1 \varphi_N^2(u) du = 1$.

10.5.6. In Theorem 10.5.1, show that the minimum value of $W_\varphi(\Delta)$ is given by $\sum_{j=1}^{n_2} a_\varphi(j)$ and that it is nonpositive.

10.5.7. Show that $E_\Delta[W_\varphi(0)] = E_0[W_\varphi(-\Delta)]$.

10.5.8. Consider the hypotheses (10.4.4). Suppose we select the score function $\varphi(u)$ and the corresponding test based on W_φ . Suppose we want to determine the sample size $n = n_1 + n_2$ for this test of significance level α to detect the alternative Δ^* with approximate power γ^* . Assuming that the sample sizes n_1 and n_2 are the same, show that

$$n \approx \left(\frac{(z_\alpha - z_{\gamma^*})2\tau_\varphi}{\Delta^*} \right)^2. \quad (10.5.38)$$

10.5.9. In the context of this section, show the following invariances:

- (a) Show that the parameter τ_φ , (10.5.24), is a scale functional as defined in Exercise 10.1.4.

(b) Show that part (a) implies that the efficacy, (10.5.20), is invariant to the location and varies indirectly with scale.

(c) Suppose Z is a scale and location transformation of a random variable X ; i.e., $Z = a(X - b)$, where $a > 0$ and $-\infty < b < \infty$. Show that $I(f_Z) = a^{-2}I(f_X)$.

10.5.10. Consider the scale parameter τ_φ , (10.5.24), when normal scores are used; i.e., $\varphi(u) = \Phi^{-1}(u)$. Suppose we are sampling from a $N(\mu, \sigma^2)$ distribution. Show that $\tau_\varphi = \sigma$.

10.5.11. In the context of Example 10.5.2, obtain the results in expression (10.5.32).

10.5.12. Let the scores $a(i)$ be generated by $a_\varphi(i) = \varphi[i/(n+1)]$, for $i = 1, \dots, n$, where $\int_0^1 \varphi(u) du = 0$ and $\int_0^1 \varphi^2(u) du = 1$. Using Riemann sums, with subintervals of equal length, of the integrals $\int_0^1 \varphi(u) du$ and $\int_0^1 \varphi^2(u) du$, show that $\sum_{i=1}^n a(i) \approx 0$ and $\sum_{i=1}^n a^2(i) \approx n$.

10.5.13. Consider the sign scores test procedure discussed in Example 10.5.4.

(a) Show that $W_S = 2W_S^* - n_2$, where $W_S^* = \#\{R(Y_j) > \frac{n+1}{2}\}$. Hence W_S^* is an equivalent test statistic. Find the null mean and variance of W_S .

(b) Show that $W_S^* = \#\{Y_j > \theta^*\}$, where θ^* is the combined sample median.

(c) Suppose n is even. Letting $W_{XS}^* = \#\{X_i > \theta^*\}$, show that we can table W_S^* in the following 2×2 contingency table with all margins fixed:

	Y	X	
No. items $> \theta^*$	W_S^*	W_{XS}^*	$\frac{n}{2}$
No. items $< \theta^*$	$n_2 - W_S^*$	$n_1 - W_{XS}^*$	$\frac{n}{2}$
	n_2	n_1	n

Show that the usual χ^2 goodness-of-fit is the same as Z_S^2 , where Z_S is the standardized z -test based on W_S . This is often called **Mood's median test**; see Example 10.5.4.

10.5.14. Recall the data discussed in Example 10.5.3.

(a) Obtain the contingency table described in Exercise 10.5.13.

(b) Obtain the χ^2 goodness-of-fit test statistic associated with the table and use it to test at level 0.05 the hypotheses $H_0 : \Delta = 0$ versus $H_1 : \Delta \neq 0$.

(c) Obtain the point estimate of Δ given in expression (10.5.37).

10.5.15. Optimal signed-rank based methods also exist for the one-sample problem. In this exercise, we briefly discuss these methods. Let X_1, X_2, \dots, X_n follow the location model

$$X_i = \theta + e_i, \quad (10.5.39)$$

where e_1, e_2, \dots, e_n are iid with pdf $f(x)$, which is symmetric about 0; i.e., $f(-x) = f(x)$.

- (a) Show that under symmetry the optimal two-sample score function (10.5.26) satisfies

$$\varphi_f(1-u) = -\varphi_f(u), \quad 0 < u < 1; \quad (10.5.40)$$

that is, $\varphi_f(u)$ is an odd function about $\frac{1}{2}$. Show that a function satisfying (10.5.40) is 0 at $u = \frac{1}{2}$.

- (b) For a two-sample score function $\varphi(u)$ that is odd about $\frac{1}{2}$, define the function $\varphi^+(u) = \varphi[(u+1)/2]$, i.e., the top half of $\varphi(u)$. Note that the domain of $\varphi^+(u)$ is the interval $(0, 1)$. Show that $\varphi^+(u) \geq 0$, provided $\varphi(u)$ is nondecreasing.
- (c) Assume for the remainder of the problem that $\varphi^+(u)$ is nonnegative and non-decreasing on the interval $(0, 1)$. Define the scores $a^+(i) = \varphi^+[i/(n+1)]$, $i = 1, 2, \dots, n$, and the corresponding statistic

$$W_{\varphi^+} = \sum_{i=1}^n \text{sgn}(X_i) a^+(R|X_i|). \quad (10.5.41)$$

Show that W_{φ^+} reduces to a linear function of the signed-rank test statistic (10.3.2) if $\varphi(u) = 2u - 1$.

- (d) Show that W_{φ^+} reduces to a linear function of the sign test statistic (10.2.3) if $\varphi(u) = \text{sgn}(2u - 1)$.

Note: Suppose Model (10.5.39) is true and we take $\varphi(u) = \varphi_f(u)$, where $\varphi_f(u)$ is given by (10.5.26). If we choose $\varphi^+(u) = \varphi[(u+1)/2]$ to generate the signed-rank scores, then it can be shown that the corresponding test statistic W_{φ^+} is optimal, among all signed-rank tests.

- (e) Consider the hypotheses

$$H_0 : \theta = 0 \text{ versus } H_1 : \theta > 0.$$

Our decision rule for the statistic W_{φ^+} is to reject H_0 in favor of H_1 if $W_{\varphi^+} \geq k$, for some k . Write W_{φ^+} in terms of the anti-ranks, (10.3.5). Show that W_{φ^+} is distribution-free under H_0 .

- (f) Determine the mean and variance of W_{φ^+} under H_0 .
- (g) Assuming that, when properly standardized, the null distribution is asymptotically normal, determine the asymptotic test.

10.6 *Adaptive Procedures

In the last section, we presented fully efficient rank-based procedures for testing and estimation. As with mle methods, though, the underlying form of the distribution must be known in order to select the optimal rank score function. In practice, often the underlying distribution is not known. In this case, we could select a score function, such as the Wilcoxon, which is fairly efficient for moderate- to heavy-tailed

error distributions. Or if the distribution of the errors is thought to be quite close to a normal distribution, then the normal scores would be a proper choice. Suppose we use a technique that bases the score selection on the data. These techniques are called **adaptive** procedures. Such a procedure could attempt to estimate the score function; see, for example, Naranjo and McKean (1997). However, large data sets are often needed for these. There are other adaptive procedures that attempt to select a score from a finite class of scores based on some criteria. In this section, we look at an adaptive testing procedure that retains the distribution-free property.

Frequently, an investigator is tempted to evaluate several test statistics associated with a single hypothesis and then use the one statistic that best supports his or her position, usually rejection. Obviously, this type of procedure changes the actual significance level of the test from the nominal α that is used. However, there is a way in which the investigator can first look at the data and then select a test statistic without changing this significance level. For illustration, suppose there are three possible test statistics, W_1, W_2 , and W_3 , of the hypothesis H_0 with respective critical regions C_1, C_2 , and C_3 such that $P(W_i \in C_i; H_0) = \alpha$, $i = 1, 2, 3$. Moreover, suppose that a statistic Q , based upon the same data, selects one and only one of the statistics W_1, W_2, W_3 , and that W is then used to test H_0 . For example, we choose to use the test statistic W_i if $Q \in D_i$, $i = 1, 2, 3$, where the events defined by D_1, D_2 , and D_3 are mutually exclusive and exhaustive. Now if Q and each W_i are independent when H_0 is true, then the probability of rejection, using the entire procedure (selecting and testing), is, under H_0 ,

$$\begin{aligned} & P_{H_0}(Q \in D_1, W_1 \in C_1) + P_{H_0}(Q \in D_2, W_2 \in C_2) + P_{H_0}(Q \in D_3, W_3 \in C_3) \\ &= P_{H_0}(Q \in D_1)P_{H_0}(W_1 \in C_1) + P_{H_0}(Q \in D_2)P_{H_0}(W_2 \in C_2) \\ &\quad + P_{H_0}(Q \in D_3)P_{H_0}(W_3 \in C_3) \\ &= \alpha[P_{H_0}(Q \in D_1) + P_{H_0}(Q \in D_2) + P_{H_0}(Q \in D_3)] = \alpha. \end{aligned}$$

That is, the procedure of selecting W_i using an independent statistic Q and then constructing a test of significance level α with the statistic W_i has overall significance level α .

Of course, the important element in this procedure is the ability to be able to find a selector Q that is independent of each test statistic W . This can frequently be done by using the fact that complete sufficient statistics for the parameters, given by H_0 , are independent of every statistic whose distribution is free of those parameters. For illustration, if independent random samples of sizes n_1 and n_2 arise from two normal distributions with respective means μ_1 and μ_2 and common variance σ^2 , then the complete sufficient statistics \bar{X}, \bar{Y} , and

$$V = \sum_1^{n_1} (X_i - \bar{X})^2 + \sum_1^{n_2} (Y_i - \bar{Y})^2$$

for μ_1, μ_2 , and σ^2 are independent of every statistic whose distribution is free of

μ_1, μ_2 , and σ^2 , such as the statistics

$$\frac{\sum_{i=1}^{n_1} (X_i - \bar{X})^2}{\sum_{i=1}^{n_2} (Y_i - \bar{Y})^2}, \quad \frac{\sum_{i=1}^{n_1} |X_i - \text{median}(X_i)|}{\sum_{i=1}^{n_2} |Y_i - \text{median}(Y_i)|}, \quad \frac{\text{range}(X_1, X_2, \dots, X_{n_1})}{\text{range}(Y_1, Y_2, \dots, Y_{n_2})}.$$

Thus, in general, we would hope to be able to find a selector Q that is a function of the complete sufficient statistics for the parameters, under H_0 , so that it is independent of the test statistic.

It is particularly interesting to note that it is relatively easy to use this technique in *nonparametric* methods by using the independence result based upon complete sufficient statistics for *parameters*. For the situations here, we must find complete sufficient statistics for a cdf, F , of the continuous type. In Chapter 7, it is shown that the order statistics $Y_1 < Y_2 < \dots < Y_n$ of a random sample of size n from a distribution of the continuous type with pdf $F'(x) = f(x)$ are sufficient statistics for the “parameter” f (or F). Moreover, if the family of distributions contains all probability density functions of the continuous type, the family of joint probability density functions of Y_1, Y_2, \dots, Y_n is also complete. That is, the order statistics Y_1, Y_2, \dots, Y_n are complete sufficient statistics for the parameters f (or F).

Accordingly, our selector Q is based upon those complete sufficient statistics, the order statistics under H_0 . This allows us to independently choose a distribution-free test appropriate for this type of underlying distribution, and thus increase the power of our test.

A statistical test that maintains the significance level close to a desired significance level α for a wide variety of underlying distributions with good (not necessarily the best for any one type of distribution) power for all these distributions is described as being *robust*. As an illustration, the pooled t -test (Student’s t) used to test the equality of the means of two normal distributions is quite robust *provided* that the underlying distributions are rather close to normal ones with common variance. However, if the class of distributions includes those that are not too close to normal ones, such as contaminated normal distributions, the test based upon t is *not* robust; the significance level is not maintained and the power of the t -test can be quite low for heavy-tailed distributions. As a matter of fact, the test based on the Mann–Whitney–Wilcoxon statistic (Section 10.4) is a much more robust test than that based upon t if the class of distributions includes those with heavy tails.

In the following example, we illustrate a robust, adaptive, distribution-free procedure in the setting of the two-sample problem.

Example 10.6.1. Let X_1, X_2, \dots, X_{n_1} be a random sample from a continuous-type distribution with cdf $F(x)$ and let Y_1, Y_2, \dots, Y_{n_2} be a random sample from a distribution with cdf $F(x - \Delta)$. Let $n = n_1 + n_2$ denote the combined sample size. We test

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0,$$

by using one of four distribution-free statistics, one being the Wilcoxon and the other three being modifications of the Wilcoxon. In particular, the test statistics

are

$$W_i = \sum_{j=1}^{n_2} a_i[R(Y_j)], \quad i = 1, 2, 3, 4, \quad (10.6.1)$$

where

$$a_i(j) = \varphi_i[j/(n+1)],$$

and the four functions are displayed in Figure 10.6.1. The score function $\varphi_1(u)$ is the Wilcoxon. The score function $\varphi_2(u)$ is the sign score function. The score function $\varphi_3(u)$ is good for short-tailed distributions, and $\varphi_4(u)$ is good for long, right-skewed distributions with shift alternatives.

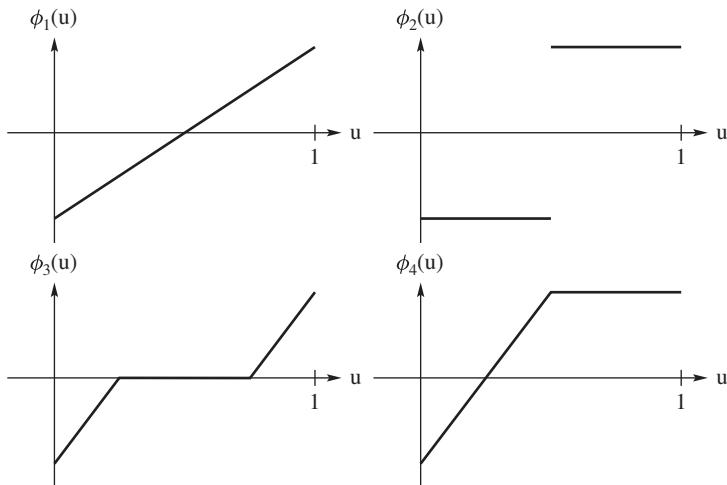

Figure 10.6.1: Plots of the score functions $\varphi_1(u)$, $\varphi_2(u)$, $\varphi_3(u)$, and $\varphi_4(u)$.

We combine the two samples into one denoting the order statistics of the combined sample by $V_1 < V_2 < \dots < V_n$. These are complete sufficient statistics for $F(x)$ under the null hypothesis. For $i = 1, \dots, 4$, the test statistic W_i is distribution free under H_0 and, in particular, the distribution of W_i does not depend on $F(x)$. Therefore, each W_i is independent of V_1, V_2, \dots, V_n . We use a pair of selector statistics (Q_1, Q_2) , which are functions of V_1, V_2, \dots, V_n , and hence are also independent of each W_i . The first is

$$Q_1 = \frac{\overline{U}_{.05} - \overline{M}_{.5}}{\overline{M}_{.5} - \overline{L}_{.05}}, \quad (10.6.2)$$

where $\overline{U}_{.05}$, $\overline{M}_{.5}$, and $\overline{L}_{.05}$ are the averages of the largest 5% of the Vs, the middle 50% of the Vs, and the smallest 5% of the Vs, respectively. If Q_1 is large (say 2 or more), then the right tail of the distribution seems longer than the left tail; that is, there is an indication that the distribution is skewed to the right. On the other hand, if $Q_1 < \frac{1}{2}$, the sample indicates that the distribution may be skewed to the

left. The second selector statistic is

$$Q_2 = \frac{\bar{U}_{.05} - \bar{L}_{.05}}{\bar{U}_{.5} - \bar{L}_{.5}}. \quad (10.6.3)$$

Large values of Q_2 indicate that the distribution is heavy-tailed, while small values indicate that the distribution is light-tailed. Rules are needed for score selection, and here we make use of the benchmarks proposed in an article by Hogg et al. (1975). These rules are tabulated below, along with their benchmarks:

Benchmark	Distribution Indicated	Score Selected
$Q_2 > 7$	Heavy-tailed symmetric	φ_2
$Q_1 > 2$ and $Q_2 < 7$	Right-skewed	φ_4
$Q_1 \leq 2$ and $Q_2 \leq 2$	Light-tailed symmetric	φ_3
Elsewhere	Moderate heavy-tailed	φ_1

Hogg et al. (1975) performed a Monte Carlo power study of this adaptive procedure over a number of distributions with different kurtosis and skewness coefficients. In the study, both the adaptive procedure and the Wilcoxon test maintain their α level over the distributions, but the Student t does not. Moreover, the Wilcoxon test has better power than the t -test, as the distribution deviates much from the normal (kurtosis = 3 and skewness = 0), but the adaptive procedure is much better than the Wilcoxon for the short-tailed distributions, the very heavy-tailed distributions, and the highly skewed distributions that are considered in the study. ■

Remark 10.6.1 (Computation for the Adaptive Procedure). An R implementation of Hogg's adaptive procedure as discussed in Example 10.6.1 can be found in the R package `npsm` developed by Kloke and McKean (2014); see their Section 3.6. The R function is `hogg.test`. For illustration, consider the normal data discussed in Example 10.5.3. Here are the code and results:

```
load("examp1053.rda"); hogg.test(y,x)
Scores Selected: Wilcoxon; p.value 0.11984
```

Hence, for this data, Hogg's procedure selected Wilcoxon scores. As another example, consider the waterwheel data given in Example 10.4.1. In this case the computation results in:

```
load("waterwheel.rda"); hogg.test(grp2,grp1)
Scores Selected: bent; p.value 0.63494
```

The selected score is the bent score which is the score function $\varphi_4(u)$ in Hogg's procedure. As the boxplot for the combined samples indicates the data are right-skewed, an indication that the score selection is appropriate. ■

The adaptive distribution-free procedure that we have discussed is for testing. Suppose we have a location model and were interested in estimating the shift in locations Δ . For example, if the true F is a normal cdf, then a good choice for the estimator of Δ would be the estimator based on the normal scores procedure discussed in Example 10.5.1. The estimators, though, are not distribution free and, hence, the above reasoning does not hold. Also, the combined sample observations

$X_1, \dots, X_{n_1}, Y_1, \dots, Y_{n_2}$ are not identically distributed. There are adaptive procedures based on residuals $X_1, \dots, X_{n_1}, Y_1 - \widehat{\Delta}, \dots, Y_{n_2} - \widehat{\Delta}$, where $\widehat{\Delta}$ is an initial estimator of Δ ; see page 237 of Hettmansperger and McKean (2011) for discussion and Section 7.6 of Kloke and McKean (2014) for an R implementation.

EXERCISES

10.6.1. In Exercises 10.6.2 and 10.6.3, the student is asked to apply the adaptive procedure described in Example 10.6.1 to real data sets. The hypotheses of interest are

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0,$$

where $\Delta = \mu_Y - \mu_X$. The four distribution-free test statistics are

$$W_i = \sum_{j=1}^{n_2} a_i[R(Y_j)], \quad i = 1, 2, 3, 4, \quad (10.6.4)$$

where

$$a_i(j) = \varphi_i[j/(n+1)],$$

and the score functions are given by

$$\begin{aligned} \varphi_1(u) &= 2u - 1, \quad 0 < u < 1 \\ \varphi_2(u) &= \operatorname{sgn}(2u - 1), \quad 0 < u < 1 \\ \varphi_3(u) &= \begin{cases} 4u - 1 & 0 < u \leq \frac{1}{4} \\ 0 & \frac{1}{4} < u \leq \frac{3}{4} \\ 4u - 3 & \frac{3}{4} < u < 1 \end{cases} \\ \varphi_4(u) &= \begin{cases} 4u - (3/2) & 0 < u \leq \frac{1}{2} \\ 1/2 & \frac{1}{2} < u < 1. \end{cases} \end{aligned}$$

Note that we have adjusted the fourth score $\varphi_4(u)$ in Figure 10.6.1 so that it integrates to 0 over the interval $(0, 1)$.

The theory of Section 10.5 states that, under H_0 , the distribution of W_i is asymptotically normal with mean 0 and variance

$$\operatorname{Var}_{H_0}(W_i) = \frac{n_1 n_2}{n-1} \left[\frac{1}{n} \sum_{j=1}^n a_i^2(j) \right].$$

Note, however, that the scores have not been standardized, so their squares integrate to 1 over the interval $(0, 1)$. Hence, do not replace the term in brackets by 1. If $n_1 = n_2 = 15$, find $\operatorname{Var}_{H_0}(W_i)$, for $i = 1, \dots, 4$.

10.6.2. Consider the data in Example 10.5.3 and the hypotheses

$$H_0 : \Delta = 0 \text{ versus } H_1 : \Delta > 0,$$

where $\Delta = \mu_Y - \mu_X$. Apply the adaptive procedure described in Example 10.6.1 with the tests defined in Exercise 10.6.1 to test these hypotheses. Obtain the p -value of the test.

10.6.3. Let $F(x)$ be a distribution function of a distribution of the continuous type that is symmetric about its median θ . We wish to test $H_0 : \theta = 0$ against $H_1 : \theta > 0$. Use the fact that the $2n$ values, X_i and $-X_i$, $i = 1, 2, \dots, n$, after ordering, are complete sufficient statistics for F , provided that H_0 is true.

- (a) As in Exercise 10.5.15, determine the one-sample signed-rank test statistics corresponding to the two-sample score functions $\varphi_1(u)$, $\varphi_2(u)$, and $\varphi_3(u)$ defined in the last exercise. Use the asymptotic test statistics. Note that these score functions are odd about $\frac{1}{2}$; hence, their top halves serve as score functions for signed-rank statistics.
- (b) We are assuming symmetric distributions in this problem; hence, we use only Q_2 as our score selector. If $Q_2 \geq 7$, then select $\varphi_2(u)$; if $2 < Q_2 < 7$, then select $\varphi_1(u)$; and finally, if $Q_2 \leq 2$, then select $\varphi_3(u)$. Construct this adaptive distribution-free test.
- (c) Use your adaptive procedure on Darwin's *Zea mays* data; see Example 10.3.1. Obtain the p -value.

10.7 Simple Linear Model

In this section, we consider the simple linear model and briefly develop the rank-based procedures for it.

Suppose the responses Y_1, Y_2, \dots, Y_n follow the model

$$Y_i = \alpha + \beta(x_i - \bar{x}) + \varepsilon_i, \quad i = 1, 2, \dots, n, \quad (10.7.1)$$

where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid with continuous cdf $F(x)$ and pdf $f(x)$. In this model, the variables x_1, x_2, \dots, x_n are considered fixed. Often x is referred to as a **predictor** of Y . Also, the centering, using \bar{x} , is for convenience (without loss of generality) and we do not use it in the examples of this section. The parameter β is the slope parameter, which is the expected change in Y (provided expectations exist) when x increases by one unit. A natural null hypothesis is

$$H_0 : \beta = 0 \text{ versus } H_1 : \beta \neq 0. \quad (10.7.2)$$

Under H_0 , the distribution of Y is free of x .

In Chapter 3 of Hettmansperger and McKean (2011), rank-based procedures for linear models are presented from a geometric point of view; see also Exercises 10.9.11–10.9.12 of Section 10.9. Here, it is easier to present a development which parallels the preceding sections. Hence we introduce a rank test of H_0 and then invert the test to estimate β . Before doing this, though, we present an example that shows that the two-sample location problem of Section 10.4 is a regression problem.

Example 10.7.1. As in Section 10.4, let X_1, X_2, \dots, X_{n_1} be a random sample from a distribution with a continuous cdf $F(x - \alpha)$, where α is a location parameter. Let Y_1, Y_2, \dots, Y_{n_2} be a random sample with cdf $F(x - \alpha - \Delta)$. Hence Δ is the shift between the cdfs of X_i and Y_j . Redefine the observations as $Z_i = X_i$, for

$i = 1, \dots, n_1$, and $Z_{n_1+i} = Y_i$, for $i = n_1 + 1, \dots, n$, where $n = n_1 + n_2$. Let c_i be 0 or 1 depending on whether $1 \leq i \leq n_1$ or $n_1 + 1 \leq i \leq n$. Then we can write the two sample location models as

$$Z_i = \alpha + \Delta c_i + \varepsilon_i, \quad (10.7.3)$$

where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid with cdf $F(x)$. Hence the shift in locations is the slope parameter from this viewpoint. ■

Suppose the regression model (10.7.1) holds and, further, that H_0 is true. Then we would expect that Y_i and $x_i - \bar{x}$ are not related and, in particular, that they are uncorrelated. Hence one could consider $\sum_{i=1}^n (x_i - \bar{x})Y_i$ as a test statistic. As Exercise 9.6.11 of Chapter 9 shows, if we additionally assume that the random errors ε_i are normally distributed, this test statistic, properly standardized, is the likelihood ratio test statistic. Reasoning in the same way, for a specified score function we would expect that $a_\varphi(R(Y_i))$ and $x_i - \bar{x}$ are uncorrelated, under H_0 . Therefore, consider the test statistic

$$T_\varphi = \sum_{i=1}^n (x_i - \bar{x})a_\varphi(R(Y_i)), \quad (10.7.4)$$

where $R(Y_i)$ denotes the rank of Y_i among Y_1, \dots, Y_n and $a_\varphi(i) = \varphi(i/(n+1))$ for a nondecreasing score function $\varphi(u)$ that is standardized, so that $\int \varphi(u) du = 0$ and $\int \varphi^2(u) du = 1$. Values of T_φ close to 0 indicate H_0 is true.

Assume H_0 is true. Then Y_1, \dots, Y_n are iid random variables. Hence any permutation of the integers $\{1, 2, \dots, n\}$ is equilike to be the ranks of Y_1, \dots, Y_n . So the distribution of T_φ is free of $F(x)$. Note that the distribution does depend on x_1, x_2, \dots, x_n . Thus, tables of the distribution are not available, although with high-speed computing, this distribution can be generated. Because $R(Y_i)$ is uniformly distributed on the integers $\{1, 2, \dots, n\}$, it is easy to show that the null expectation of T_φ is zero. The null variance follows that of W_φ of Section 10.5, so we have left the details for Exercise 10.7.4. To summarize, the null moments are given by

$$E_{H_0}(T_\varphi) = 0 \quad \text{and} \quad \text{Var}_{H_0}(T_\varphi) = \frac{1}{n-1} s_a^2 \sum_{i=1}^n (x_i - \bar{x})^2, \quad (10.7.5)$$

where s_a^2 is the mean sum of the squares of the scores (10.5.6). Also, it can be shown that the test statistic is asymptotically normal. Therefore, an asymptotic level α decision rule for the hypotheses (10.7.2) with the two-sided alternative is given by

$$\text{Reject } H_0 \text{ in favor of } H_1 \text{ if } |z| = \left| \frac{T_\varphi}{\sqrt{\text{Var}_{H_0}(T_\varphi)}} \right| \geq z_{\alpha/2}. \quad (10.7.6)$$

The associated process is given by

$$T_\varphi(\beta) = \sum_{i=1}^n (x_i - \bar{x})a_\varphi(R(Y_i - x_i\beta)). \quad (10.7.7)$$

Hence the corresponding estimate of β is given by $\widehat{\beta}_\varphi$, which solves the estimating equations

$$T_\varphi(\widehat{\beta}_\varphi) \approx 0. \quad (10.7.8)$$

Similar to Theorem 10.5.1, it can be shown that $T_\varphi(\beta)$ is a decreasing step function of β that steps down at each sample slope $(Y_j - Y_i)/(x_j - x_i)$, for $i \neq j$. Thus the estimate exists. It cannot be obtained in closed form, but simple iterative techniques can be used to find the solution. In the regression problem, though, prediction of Y is often of interest, which also requires an estimate of α . Notice that such an estimate can be obtained as a location estimate based on residuals. This is discussed in some detail in Section 3.5.2 of Hettmansperger and McKean (2011). For our purposes, we consider the median of the residuals; that is, we estimate α as

$$\widehat{\alpha} = \text{med}\{Y_i - \widehat{\beta}_\varphi(x_i - \bar{x})\}. \quad (10.7.9)$$

Remark 10.7.1 (Computation). The Wilcoxon estimates of slope and intercept are computed by several packages. We recommend the CRAN package **Rfit** developed by Kloke and McKean (2012). Chapter 4 of the book by Kloke and McKean (2014) discusses the use of **Rfit** for the simple regression model (10.7.1). **Rfit** has code for many score functions, including the Wilcoxon scores, normal scores, as well as scores appropriate for skewed error distributions. The computations in this section are performed by **Rfit**. Also, the minitab command **rregr** obtains the Wilcoxon fit. Terpstra and McKean (2005) have written a collection of R functions, **ww**, which obtains the fit using Wilcoxon scores. ■

Example 10.7.2 (Telephone Data). Consider the regression data discussed in Exercise 9.6.3. Recall that the responses (y) for this data set are the numbers of telephone calls (tens of millions) made in Belgium for the years 1950–1973, while time in years serves as the predictor variable (x). The data are plotted in Figure 10.7.1. The data are in the file **telephone.rda**. For this example, we use Wilcoxon scores to fit Model (10.7.1). The code and partial results (including the plot with overlaid fits) are:

```
fitls <- lm(numcall~year); fitrb <- rfit(numcall~year)
fitls$coef; fitrb$coef # Result -26.0, 0.504; -7.1, 0.145
plot(numcall~year,xlab="Year",ylab="Number of calls")
abline(fitls); abline(fitrb,lty=2)
legend(50,15,c("LS-Fit","Wilcoxon-Fit"),lty=c(1,2))
```

Thus, the Wilcoxon fitted value is $\widehat{Y}_{\varphi,i} = -7.1 + 0.145x_i$ which is plotted in Figure 10.7.1. The least squares fit $\widehat{Y}_{LS,i} = -26.0 + 0.504x_i$, is also plotted. Note that the Wilcoxon fit is much less sensitive to the outliers than the least squares fit.

The outliers in this data set were recording errors; see page 25 of Rousseeuw and Leroy (1987) for more discussion. ■

Similar to Lemma 10.2.1, a translation property holds for the process $T(\beta)$ given by

$$E_\beta[T(0)] = E_0[T(-\beta)]; \quad (10.7.10)$$

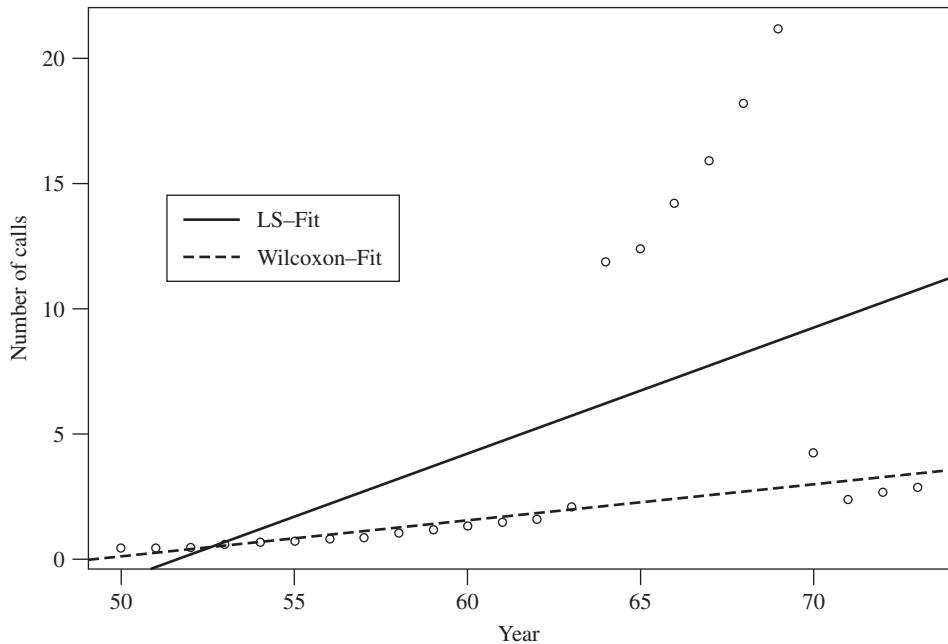

Figure 10.7.1: Plot of telephone data, Example 10.7.2, overlaid with Wilcoxon and LS fits.

see Exercise 10.7.2. Further, as Exercise 10.7.5 shows, this property implies that the power curve for the one-sided tests of $H_0 : \beta = 0$ are monotone, assuring the unbiasedness of the tests based on T_φ .

We can now derive the efficacy of the process. Let $\mu_T(\beta) = E_\beta[T(0)]$ and $\sigma_T^2(0) = \text{Var}_0[T(0)]$. Expression (10.7.5) gives the result for $\sigma_T^2(0)$. Recall that for the mean $\mu_T(\beta)$, we need its derivative at 0. We freely use the relationship between rankings and the empirical cdf and then approximate this empirical cdf with the true cdf. Hence

$$\begin{aligned}
\mu_T(\beta) = E_\beta[T(0)] &= E_0[T(-\beta)] = \sum_{i=1}^n (x_i - \bar{x}) E_0[a_\varphi(R(Y_i + x_i\beta))] \\
&= \sum_{i=1}^n (x_i - \bar{x}) E_0 \left[\varphi \left(\frac{n\hat{F}_n(Y_i + x_i\beta)}{n+1} \right) \right] \\
&\approx \sum_{i=1}^n (x_i - \bar{x}) E_0[\varphi(F(Y_i + x_i\beta))] \\
&= \sum_{i=1}^n (x_i - \bar{x}) \int_{-\infty}^{\infty} \varphi(F(y + x_i\beta)) f(y) dy. \quad (10.7.11)
\end{aligned}$$

Differentiating this last expression, we have

$$\mu'_T(\beta) = \sum_{i=1}^n (x_i - \bar{x}) x_i \int_{-\infty}^{\infty} \varphi'(F(y + x_i \beta)) f(y + x_i \beta) f(y) dy,$$

which yields

$$\mu'_T(0) = \sum_{i=1}^n (x_i - \bar{x})^2 \int_{-\infty}^{\infty} \varphi'(F(y)) f^2(y) dy. \quad (10.7.12)$$

We need one assumption on the x_1, x_2, \dots, x_n ; namely, $n^{-1} \sum_{i=1}^n (x_i - \bar{x})^2 \rightarrow \sigma_x^2$, where $0 < \sigma_x^2 < \infty$. Recall that $(n-1)^{-1} s_a^2 \rightarrow 1$. Therefore, the efficacy of the process $T(\beta)$ is given by

$$\begin{aligned} c_T &= \lim_{n \rightarrow \infty} \frac{\mu'_T(0)}{\sqrt{n} \sigma_T(0)} = \lim_{n \rightarrow \infty} \frac{\sum_{i=1}^n (x_i - \bar{x})^2 \int_{-\infty}^{\infty} \varphi'(F(y)) f^2(y) dy}{\sqrt{n} \sqrt{(n-1)^{-1} s_a^2} \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \\ &= \sigma_x \int_{-\infty}^{\infty} \varphi'(F(y)) f^2(y) dy. \end{aligned} \quad (10.7.13)$$

Using this, an asymptotic power lemma can be derived for the test based on T_φ ; see expression (10.7.17) of Exercise 10.7.6. Based on this, it can be shown that the asymptotic distribution of the estimator $\hat{\beta}_\varphi$ is given by

$$\hat{\beta}_\varphi \text{ has an approximate } N \left(\beta, \tau_\varphi^2 / \sum_{i=1}^n (x_i - \bar{x})^2 \right) \text{ distribution,} \quad (10.7.14)$$

where the scale parameter τ_φ is $\tau_\varphi = (\int_{-\infty}^{\infty} \varphi'(F(y)) f^2(y) dy)^{-1}$. Koul et al. (1987) developed a consistent estimator of the scale parameter τ , which is the default estimate in the package **Rfit**. This can be used to compute a confidence interval for the slope parameter, as illustrated in Example 10.7.3.

Remark 10.7.2. The least squares (LS) estimates for Model (10.7.1) were discussed in Section 9.6 in the case that the random errors $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are iid with a $N(0, \sigma^2)$ distribution. In general, for Model (10.7.1), the asymptotic distribution of the LS estimator of β , say $\hat{\beta}_{\text{LS}}$, is:

$$\hat{\beta}_{\text{LS}} \text{ has an approximate } N \left(\beta, \sigma^2 / \sum_{i=1}^n (x_i - \bar{x})^2 \right) \text{ distribution,} \quad (10.7.15)$$

where σ^2 is the variance of ε_i . Based on (10.7.14) and (10.7.15), it follows that the ARE between the rank-based and LS estimators is given by

$$\text{ARE}(\hat{\beta}_\varphi, \hat{\beta}_{\text{LS}}) = \frac{\sigma^2}{\tau_\varphi^2}. \quad (10.7.16)$$

Hence, if Wilcoxon scores are used, this ARE is the same as the ARE between the Wilcoxon and *t*-procedures in the one- and two-sample location models. ■

Example 10.7.3 (Distance of Punts). Rasmussen (1992), page 562, presents a data set concerning distance of punts along with several predictors. The actual response is the average distance in feet of 10 punts for each of 13 punters. As a predictor, we consider the average hang-time in seconds (the time the punted football is in the air). The data are in the file `punter.rda`. Based on the plot (see Exercise 10.7.1), the simple linear model seems reasonable as an initial fit. Next is the code and partial results of the Wilcoxon fit:

```
fit <- rfit(distance ~ hangtime); summary(fit)
    Estimate Std. Error t.value p.value
(Intercept) -18.180    51.201 -0.3551 0.729254
hangtime      41.010   12.882  3.1834 0.008708 **
```

The second line of the summary table gives the Wilcoxon estimate of the slope (41.01) and the standard error of the estimate (12.89). Hence, we predict that the football travels an additional 41 feet for each additional second of hang-time. An approximate 95% confidence interval for the true slope, using the t -critical with 11 degrees of freedom is (12.66, 69.36). So with approximate confidence of 95% the slope differs from 0. ■

EXERCISES

10.7.1. Consider the data on football punts in Example 10.7.3.

- (a) Obtain the scatterplot of distance versus hang-time and overlay the Wilcoxon fit.
- (b) As a second predictor consider overall strength of the kicker which is in the variable `strength`. Obtain the scatterplot of distance versus strength and overlay the Wilcoxon fit. What is the meaning of the slope parameter for this predictor. Answer using a 95% confidence interval for the slope.

10.7.2. Establish expression (10.7.10). To do this, note first that the expression is the same as

$$E_\beta \left[\sum_{i=1}^n (x_i - \bar{x}) a_\varphi(R(Y_i)) \right] = E_0 \left[\sum_{i=1}^n (x_i - \bar{x}) a_\varphi(R(Y_i + x_i \beta)) \right].$$

Show that the cdfs of Y_i (under β) and $Y_i + (x_i - \bar{x})\beta$ (under 0) are the same.

10.7.3. Suppose we have a two-sample model given by (10.7.3). Assuming Wilcoxon scores, show that the test statistic (10.7.4) is equivalent to the Wilcoxon test statistic found in expression (10.4.5).

10.7.4. Show that the null variance of the test statistic T_φ is the value given in (10.7.5).

10.7.5. Show that the translation property (10.7.10) implies that the power curve for either one-sided test based on the test statistic T_φ of $H_0 : \beta = 0$ is monotone.

10.7.6. Consider the sequence of local alternatives given by the hypotheses

$$H_0 : \beta = 0 \text{ versus } H_{1n} : \beta = \beta_n = \frac{\beta_1}{\sqrt{n}},$$

where $\beta_1 > 0$. Let $\gamma(\beta)$ be the power function discussed in Exercise 10.7.5 for an asymptotic level α test based on the test statistic T_φ . Using the mean value theorem to approximate $\mu_T(\beta_n)$, sketch a proof of the limit

$$\lim_{n \rightarrow \infty} \gamma(\beta_n) = 1 - \Phi(z_\alpha - c_T \beta_1). \quad (10.7.17)$$

10.8 Measures of Association

In the last section, we discussed the simple linear regression model in which the random variables, Y s, were the responses or dependent variables, while the x s were the independent variables and were thought of as fixed. Regression models occur in several ways. In an experimental design, the values of the independent variables are prespecified and the responses are observed. Bioassays (dose-response experiments) are examples. The doses are fixed and the responses are observed. If the experimental design is performed in a controlled environment (for example, all other variables are controlled), it may be possible to establish cause and effect between x and Y . On the other hand, in observational studies both the x s and Y s are observed. In the regression setting, we are still interested in predicting Y in terms of x , but usually cause and effect between x and Y are precluded in such studies (other variables besides x may be changing).

In this section, we focus on observational studies but are interested in the strength of the association between Y and x . So both X and Y are treated as random variables in this section and the underlying distribution of interest is the bivariate distribution of the pair (X, Y) . We assume that this bivariate distribution is continuous with cdf $F(x, y)$ and pdf $f(x, y)$.

Hence, let (X, Y) be a pair of random variables. A natural null model (baseline model) is that there is no relationship between X and Y ; that is, the null hypothesis is given by $H_0 : X$ and Y are independent. Alternatives, though, depend on which measure of association is of interest. For example, if we are interested in the correlation between X and Y , we use the correlation coefficient ρ (Section 9.7) as our measure of the association. A two-sided alternative in this case is $H_1 : \rho \neq 0$. Recall that independence between X and Y implies that $\rho = 0$, but that the converse is not true. However, the contrapositive is true; that is, $\rho \neq 0$ implies that X and Y are dependent. So, in rejecting H_0 , we conclude that X and Y are dependent. Furthermore, the size of ρ indicates the strength of the correlation between X and Y .

10.8.1 Kendall's τ

The first measure of association that we consider in this section is a measure of the *monotonicity* between X and Y . Monotonicity is an easily understood association between X and Y . Let (X_1, Y_1) and (X_2, Y_2) be independent pairs with the same

bivariate distribution (discrete or continuous). We say these pairs are **concordant** if $\text{sgn}\{(X_1 - X_2)(Y_1 - Y_2)\} = 1$ and are **discordant** if $\text{sgn}\{(X_1 - X_2)(Y_1 - Y_2)\} = -1$. The variables X and Y have an increasing relationship if the pairs tend to be concordant and a decreasing relationship if the pairs tend to be discordant. A measure of this is given by **Kendall's τ** ,

$$\tau = P[\text{sgn}\{(X_1 - X_2)(Y_1 - Y_2)\} = 1] - P[\text{sgn}\{(X_1 - X_2)(Y_1 - Y_2)\} = -1]. \quad (10.8.1)$$

As Exercise 10.8.1 shows, $-1 \leq \tau \leq 1$. Positive values of τ indicate increasing monotonicity, negative values indicate decreasing monotonicity, and $\tau = 0$ reflects neither. Furthermore, as the following theorem shows, if X and Y are independent, then $\tau = 0$.

Theorem 10.8.1. *Let (X_1, Y_1) and (X_2, Y_2) be independent pairs of observations of (X, Y) , which has a continuous bivariate distribution. If X and Y are independent, then $\tau = 0$.*

Proof: Let (X_1, Y_1) and (X_2, Y_2) be independent pairs of observations with the same continuous bivariate distribution as (X, Y) . Because the cdf is continuous, the sign function is either -1 or 1 . By independence, we have

$$\begin{aligned} P[\text{sgn}(X_1 - X_2)(Y_1 - Y_2) = 1] &= P[\{X_1 > X_2\} \cap \{Y_1 > Y_2\}] \\ &\quad + P[\{X_1 < X_2\} \cap \{Y_1 < Y_2\}] \\ &= P[X_1 > X_2]P[Y_1 > Y_2] \\ &\quad + P[X_1 < X_2]P[Y_1 < Y_2] \\ &= \left(\frac{1}{2}\right)^2 + \left(\frac{1}{2}\right)^2 = \frac{1}{2}. \end{aligned}$$

Likewise, $P[\text{sgn}(X_1 - X_2)(Y_1 - Y_2) = -1] = \frac{1}{2}$; hence, $\tau = 0$. ■

Relative to Kendall's τ as the measure of association, the two-sided hypotheses of interest here are

$$H_0 : \tau = 0 \text{ versus } H_1 : \tau \neq 0. \quad (10.8.2)$$

As Exercise 10.8.1 shows, the converse of Theorem 10.8.1 is false. However, the contrapositive is true; i.e., $\tau \neq 0$ implies that X and Y are dependent. As with the correlation coefficient, in rejecting H_0 , we conclude that X and Y are dependent.

Kendall's τ has a simple unbiased estimator. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample of the cdf $F(x, y)$. Define the statistic

$$K = \binom{n}{2}^{-1} \sum_{i < j} \text{sgn}\{(X_i - X_j)(Y_i - Y_j)\}. \quad (10.8.3)$$

Note that for all $i \neq j$, the pairs (X_i, Y_i) and (X_j, Y_j) are identically distributed. Thus $E(K) = \binom{n}{2}^{-1} \binom{n}{2} E[\text{sgn}\{(X_1 - X_2)(Y_1 - Y_2)\}] = \tau$.

In order to use K as a test statistic of the hypotheses (10.8.2), we need its distribution under the null hypothesis. Under H_0 , $\tau = 0$, so $E_{H_0}(K) = 0$. The

null variance of K is given by expression (10.8.6); see, for instance, page 205 of Hettmansperger (1984). If all pairs $(X_i, Y_i), (X_j, Y_j)$ of the sample are concordant then $K = 1$, indicating a strictly increasing monotone relationship. On the other hand, if all pairs are discordant then $K = -1$. Thus the range of K is contained in the interval $[-1, 1]$. Also, the summands in expression (10.8.3) are either ± 1 . From the proof of Theorem 10.8.1, the probability that a summand is 1 is $1/2$, which does not depend on the underlying distribution. Hence the statistic K is distribution-free under H_0 . The null distribution of K is symmetric about 0. This is easily seen from the fact that for each concordant pair there is an obvious discordant pair (just reverse an inequality on the Y s) and the fact that concordant and discordant pairs are equilike under H_0 . Also, it can be shown that K is asymptotically normal under H_0 . We summarize these results, without proof, in a theorem.

Theorem 10.8.2. *Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample on the bivariate random vector (X, Y) with continuous cdf $F(x, y)$. Under the null hypothesis of independence between X and Y , i.e., $F(x, y) = F_X(x)F_Y(y)$, for all (x, y) in the support of (X, Y) , the test statistic K satisfies the following properties:*

$$K \text{ is distribution free with a symmetric pmf} \quad (10.8.4)$$

$$E_{H_0}[K] = 0 \quad (10.8.5)$$

$$\text{Var}_{H_0}(K) = \frac{2}{9} \frac{2n+5}{n(n-1)} \quad (10.8.6)$$

$$\frac{K}{\sqrt{\text{Var}_{H_0}(K)}} \text{ has an asymptotic } N(0, 1) \text{ distribution.} \quad (10.8.7)$$

Most statistical computing packages compute Kendall's τ . For instance, the R function `cor.test(x, y, method=c("kendall"), exact=T)` obtains K and the test discussed above when x and y are the vectors of the X and Y observations, respectively. The computation of the p -value is with the exact distribution. We illustrate this test in the next example.

Based on the asymptotic distribution, a large sample level α test for the hypotheses (10.8.2) is to reject H_0 if $Z_K > z_{\alpha/2}$, where

$$Z_K = \frac{K}{\sqrt{2(2n+5)/9n(n-1)}}. \quad (10.8.8)$$

Example 10.8.1 (Olympic Race Times). Table 10.8.1 displays the winning times for two races in the Olympics beginning with the 1896 Olympics through the 1980 Olympics. The data were taken from Hettmansperger (1984) and can be found in the data set `olymp1500mara.rda`. The times in seconds are for the 1500 m and the marathon. The entries in the table for the marathon race are the actual times minus 2 hours. In Exercise 10.8.2 the reader is asked to create a scatterplot of the times for the two races. The plot shows a strongly increasing monotone trend with one obvious outlier (1968 Olympics). The following R code computes Kendall's τ . We have summarized the results with the estimate of Kendall's τ and the p -value of the test of no association. This p -value is based on the exact distribution.

```
cor.test(m1500, marathon, method="kendall", exact=T)
```

Table 10.8.1: Data for Example 10.8.1

Year	1500 m	Marathon*	Year	1500 m	Marathon*
1896	373.2	3530	1936	227.8	1759
1900	246.0	3585	1948	229.8	2092
1904	245.4	5333	1952	225.2	1383
1906	252.0	3084	1956	221.2	1500
1908	243.4	3318	1960	215.6	916
1912	236.8	2215	1964	218.1	731
1920	241.8	1956	1968	214.9	1226
1924	233.6	2483	1972	216.3	740
1928	233.2	1977	1976	219.2	595
1932	231.2	1896	1980	218.4	663

* Actual marathon times are 2 hours + entry.

p-value = 3.319e-06; estimates: tau 0.6947368

The test results show strong evidence to reject the hypothesis of the independence of the winning times of the races. ■

10.8.2 Spearman's Rho

As above, assume that $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ is a random sample from a bivariate continuous cdf $F(x, y)$. The population correlation coefficient ρ is a measure of linearity between X and Y . The usual estimate is the sample correlation coefficient given by

$$r = \frac{\sum_{i=1}^n (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^n (X_i - \bar{X})^2} \sqrt{\sum_{i=1}^n (Y_i - \bar{Y})^2}}; \quad (10.8.9)$$

see Section 9.7. A simple rank analog is to replace X_i by $R(X_i)$, where $R(X_i)$ denotes the rank of X_i among X_1, \dots, X_n , and likewise Y_i by $R(Y_i)$, where $R(Y_i)$ denotes the rank of Y_i among Y_1, \dots, Y_n . Upon making this substitution, the denominator of the above ratio is a constant. This results in the statistic

$$r_S = \frac{\sum_{i=1}^n (R(X_i) - \frac{n+1}{2})(R(Y_i) - \frac{n+1}{2})}{n(n^2 - 1)/12}, \quad (10.8.10)$$

which is called **Spearman's rho**. The statistic r_S is a correlation coefficient, so the inequality $-1 \leq r_S \leq 1$ is true. Further, as the following theorem shows, independence implies that the mean of r_S is 0.

Theorem 10.8.3. Suppose $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ is a sample on (X, Y) , where (X, Y) has the continuous cdf $F(x, y)$. If X and Y are independent, then $E(r_S) = 0$.

Proof: Under independence, X_i and Y_j are independent for all i and j ; hence, in particular, $R(X_i)$ is independent of $R(Y_j)$. Furthermore, $R(X_i)$ is uniformly distributed on the integers $\{1, 2, \dots, n\}$. Therefore, $E(R(X_i)) = (n+1)/2$, which leads to the result. ■

Thus the measure of association r_S can be used to test the null hypothesis of independence similar to Kendall's K . Under independence, because the X_i s are a random sample, the random vector $(R(X_1), \dots, R(X_n))$ is equilikely to assume any permutation of the integers $\{1, 2, \dots, n\}$ and, likewise, the vector of the ranks of the Y_i s. Furthermore, under independence, the random vector $[R(X_1), \dots, R(X_n), R(Y_1), \dots, R(Y_n)]$ is equilikely to assume any of the $(n!)^2$ vectors $(i_1, i_2, \dots, i_n, j_1, j_2, \dots, j_n)$, where (i_1, i_2, \dots, i_n) and (j_1, j_2, \dots, j_n) are permutations of the integers $\{1, 2, \dots, n\}$. Hence, under independence, the statistic r_S is distribution-free. The distribution is discrete and tables of it can be found, for instance, in Hollander and Wolfe (1999). Similar to Kendall's statistic K , the distribution is symmetric about zero and it has an asymptotic normal distribution with asymptotic variance $1/(n-1)$; see Exercise 10.8.7 for a proof of the null variance of r_s . A large sample level α test is to reject independence between X and Y if $|z_S| > z_{\alpha/2}$, where $z_S = \sqrt{n-1}r_s$. We record these results in a theorem, without proof.

Theorem 10.8.4. *Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample on the bivariate random vector (X, Y) with continuous cdf $F(x, y)$. Under the null hypothesis of independence between X and Y , i.e., $F(x, y) = F_X(x)F_Y(y)$, for all (x, y) in the support of (X, Y) , the test statistic r_S satisfies the following properties:*

$$r_S \text{ is distribution-free, symmetrically distributed about } 0 \quad (10.8.11)$$

$$E_{H_0}[r_S] = 0 \quad (10.8.12)$$

$$\text{Var}_{H_0}(r_S) = \frac{1}{n-1} \quad (10.8.13)$$

$$\frac{r_S}{\sqrt{\text{Var}_{H_0}(r_S)}} \text{ is asymptotically } N(0, 1). \quad (10.8.14)$$

Example 10.8.2 (Example 10.8.1, Continued). For the data in Example 10.8.1, the R code for the analysis based on Spearman's ρ is:

```
cor.test(m1500, marathon, method="spearman")
p-value = 2.021e-06; sample estimates: rho 0.9052632
```

The result is highly significant. For comparison, the value of the asymptotic test statistic is $Z_S = 0.905\sqrt{19} = 3.94$ with the p -value for a two-sided test is 0.00008; so, the results are quite similar. ■

If the samples have a strictly increasing monotone relationship, then it is easy to see that $r_S = 1$; while if they have a strictly decreasing monotone relationship, then $r_S = -1$. Like Kendall's K statistic, r_S is an estimate of a population parameter, but, except for when X and Y are independent, it is a more complicated expression than τ . It can be shown (see Kendall, 1962) that

$$E(r_S) = \frac{3}{n+1}[\tau + (n-2)(2\gamma - 1)], \quad (10.8.15)$$

where $\gamma = P[(X_2 - X_1)(Y_3 - Y_1) > 0]$. For large n , $E(r_S) \approx 6(\gamma - 1/2)$, which is a harder parameter to interpret than the measure of concordance τ .

Spearman's rho is based on Wilcoxon scores; hence, it can easily be extended to other rank score functions. Some of these measures are discussed in the exercises.

Remark 10.8.1 (Confidence Intervals). Distribution-free confidence intervals for Kendall's τ exist; see, Section 8.5 of Hollander and Wolfe (1999). As outlined in Exercise 10.8.6, it is easy to construct percentile bootstrap confidence intervals for both parameters. The R function `cor.boot.ci` in the CRAN package `npsm` obtains such confidence intervals; see Section 4.8 of Kloke and McKean (2014) for discussion. It also requires the CRAN package `boot` developed by Canty and Ripley (2017). We used this function to compute confidence intervals for τ and ρ_S :

```
library(boot); library(npsm)
cor.boot.ci(m1500,marathon,method="spearman"); # (0.719,0.955)
cor.boot.ci(m1500,marathon,method="kendall"); # (0.494,0.845)
```

EXERCISES

10.8.1. Show that Kendall's τ satisfies the inequality $-1 \leq \tau \leq 1$.

10.8.2. Consider Example 10.8.1. Let Y = winning times of the 1500 m race for a particular year and let X = winning times of the marathon for that year. Obtain a scatterplot of Y versus X , and determine the outlying point.

10.8.3. Consider the last exercise as a regression problem. Suppose we are interested in predicting the 1500 m winning time based on the marathon winning time. Assume a simple linear model and obtain the least squares and Wilcoxon (Section 10.7) fits of the data. Overlay the fits on the scatterplot obtained in Exercise 10.8.2. Comment on the fits. What does the slope parameter mean in this problem?

10.8.4. With regards to Exercise 10.8.3, a more interesting predicting problem is the prediction of winning time of either race based on year.

- (a) Make a scatterplot of the winning 1500 m race time versus year. Assume a simple linear model (does the assumption make sense?) and obtain the least squares and Wilcoxon (Section 10.7) fits of the data. Overlay the fits on the scatterplot. Comment on the fits. What does the slope parameter mean in this problem? Predict the winning time for 1984. How close was your prediction to the true winning time?
- (b) Same as part (a), except use the winning time of the marathon for that year.

10.8.5. Spearman's rho is a rank correlation coefficient based on Wilcoxon scores. In this exercise we consider a rank correlation coefficient based on a general score function. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample from a bivariate continuous cdf $F(x, y)$. Let $a(i) = \varphi(i/(n+1))$, where $\sum_{i=1}^n a(i) = 0$. In particular,

$\bar{a} = 0$. As in expression (10.5.6), let $s_a^2 = \sum_{i=1}^n a^2(i)$. Consider the rank correlation coefficient,

$$r_a = \frac{1}{s_a^2} \sum_{i=1}^n a(R(X_i))a(R(Y_i)). \quad (10.8.16)$$

- (a) Show that r_a is a correlation coefficient on the items

$$\{(a[R(X_1)], a[R(Y_1)]), (a[R(X_2)], a[R(Y_2)]), \dots, (a[R(X_n)], a[R(Y_n)])\}.$$

- (b) For the score function $\varphi(u) = \sqrt{12}(u - (1/2))$, show that $r_a = r_S$, Spearman's rho.
- (c) Obtain r_a for the sign score function $\varphi(u) = \text{sgn}(u - (1/2))$. Call this rank correlation coefficient r_{qc} . (The subscript qc is obvious from Exercise 10.8.8.)

10.8.6. Write an R function that computes a percentile bootstrap confidence interval for Kendall's τ . Run your function for the data discussed in Example 10.8.1 and compare your answer with the confidence interval for Kendall's τ given in Remark 10.8.1.

Note: The following R code obtains resampled vectors of x and y :

```
ind = 1:length(x); mat=cbind(x,y); inds=sample(ind,n,replace=T)

```

10.8.7. Consider the general score rank correlation coefficient r_a defined in Exercise 10.8.5. Consider the null hypothesis $H_0 : X$ and Y are independent.

- (a) Show that $E_{H_0}(r_a) = 0$.
- (b) Based on part (a) and H_0 , as a first step in obtaining the variance under H_0 , show that the following expression is true:

$$\text{Var}_{H_0}(r_a) = \frac{1}{s_a^4} \sum_{i=1}^n \sum_{j=1}^n E_{H_0}[a(R(X_i))a(R(X_j))]E_{H_0}[a(R(Y_i))a(R(Y_j))].$$

- (c) To determine the expectation in the last expression, consider the two cases $i = j$ and $i \neq j$. Then using uniformity of the distribution of the ranks, show that

$$\text{Var}_{H_0}(r_a) = \frac{1}{s_a^4} \frac{1}{n-1} s_a^4 = \frac{1}{n-1}. \quad (10.8.17)$$

10.8.8. Consider the rank correlation coefficient given by r_{qc} in part (c) of Exercise 10.8.5. Let Q_{2X} and Q_{2Y} denote the medians of the samples X_1, \dots, X_n and Y_1, \dots, Y_n , respectively. Now consider the four quadrants:

$$\begin{aligned} I &= \{(x, y) : x > Q_{2X}, y > Q_{2Y}\} \\ II &= \{(x, y) : x < Q_{2X}, y > Q_{2Y}\} \\ III &= \{(x, y) : x < Q_{2X}, y < Q_{2Y}\} \\ IV &= \{(x, y) : x > Q_{2X}, y < Q_{2Y}\}. \end{aligned}$$

Show essentially that

$$r_{qc} = \frac{1}{n} \{ \#(X_i, Y_i) \in I + \#(X_i, Y_i) \in III - \#(X_i, Y_i) \in II - \#(X_i, Y_i) \in IV \}. \quad (10.8.18)$$

Hence, r_{qc} is referred to as the *quadrant count* correlation coefficient.

10.8.9. Set up the asymptotic test of independence using r_{qc} of the last exercise. Then use it to test for independence between the 1500 m race times and the marathon race times of the data in Example 10.8.1.

10.8.10. Obtain the rank correlation coefficient when normal scores are used; that is, the scores are $a(i) = \Phi^{-1}(i/(n+1))$, $i = 1, \dots, n$. Call it r_N . Set up the asymptotic test of independence using r_N of the last exercise. Then use it to test for independence between the 1500 m race times and the marathon race times of the data in Example 10.8.1.

10.8.11. Suppose that the hypothesis H_0 concerns the independence of two random variables X and Y . That is, we wish to test $H_0 : F(x, y) = F_1(x)F_2(y)$, where F, F_1 , and F_2 are the respective joint and marginal distribution functions of the continuous type, against all alternatives. Let $(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)$ be a random sample from the joint distribution. Under H_0 , the order statistics of X_1, X_2, \dots, X_n and the order statistics of Y_1, Y_2, \dots, Y_n are, respectively, complete sufficient statistics for F_1 and F_2 . Use r_S , r_{qc} , and r_N to create an adaptive distribution-free test of H_0 .

Remark 10.8.2. It is interesting to note that in an adaptive procedure it would be possible to use different score functions for the X s and Y s. That is, the order statistics of the X values might suggest one score function and those of the Y s another score function. Under the null hypothesis of independence, the resulting procedure would produce an α level test. ■

10.9 Robust Concepts

In this section, we introduce some of the concepts in **robust** estimation. We introduce these concepts for the location model discussed in Sections 10.1–10.3 of this chapter and then apply them to the simple linear regression model of Section 10.7. In a review article, McKean (2004) presents three introductory lectures on robust concepts.

10.9.1 Location Model

In a few words, we say an estimator is **robust** if it is not sensitive to outliers in the data. In this section, we make this more precise for the location model. Suppose then that X_1, X_2, \dots, X_n is a random sample which follows the location model as given in Definition 10.1.2; i.e.,

$$X_i = \theta + \varepsilon_i, \quad i = 1, 2, \dots, n, \quad (10.9.1)$$

where θ is a location parameter (functional) and ε_i has cdf $F(t)$ and pdf $f(t)$. Let $F_X(t)$ and $f_X(t)$ denote the cdf and pdf of X , respectively. Then $F_X(t) = F(t - \theta)$ and $f_X(t) = f(t - \theta)$.

To illustrate the robust concepts, we use the location estimators discussed in Sections 10.1–10.3: the sample mean, the sample median, and the Hodges–Lehmann estimator. It is convenient to define these estimators in terms of their estimating equations. The **estimating equation** of the sample mean is given by

$$\sum_{i=1}^n (X_i - \theta) = 0; \quad (10.9.2)$$

i.e., the solution to this equation is $\hat{\theta} = \bar{X}$. The estimating equation for the sample median is given in expression (10.2.34), which, for convenience, we repeat:

$$\sum_{i=1}^n \text{sgn}(X_i - \theta) = 0. \quad (10.9.3)$$

Recall from Section 10.2 that the sample median minimizes the L_1 -norm. So in this section, we denote it as $\hat{\theta}_{L_1} = \text{med } X_i$. Finally, the estimating equation for the Hodges–Lehmann estimator is given by expression (10.4.27). For this section, we denote the solution to this equation by

$$\hat{\theta}_{\text{HL}} = \text{med}_{i \leq j} \left\{ \frac{X_i + X_j}{2} \right\}. \quad (10.9.4)$$

Suppose, in general, then that we have a random sample X_1, X_2, \dots, X_n , which follows the location model (10.9.1) with location parameter θ . Let $\hat{\theta}$ be an estimator of θ . Hopefully, $\hat{\theta}$ is not unduly influenced by an outlier in the sample, that is, a point that is at a distance from the other points in the sample. For a realization of the sample, this sensitivity to outliers is easy to measure. We simply add an outlier to the data set and observe the change in the estimator.

More formally, let $\mathbf{x}_n = (x_1, x_2, \dots, x_n)$ be a realization of the sample, let x be the additional point, and denote the augmented sample by $\mathbf{x}'_{n+1} = (\mathbf{x}'_n, x)$. Then a simple measure is the rate of change in the estimate due to x relative to the mass of x , $(1/(n+1))$; i.e.,

$$S(x; \hat{\theta}) = \frac{\hat{\theta}(\mathbf{x}'_{n+1}) - \hat{\theta}(\mathbf{x}_n)}{1/(n+1)}. \quad (10.9.5)$$

This is called the **sensitivity curve** of the estimate $\hat{\theta}$.

As examples, consider the sample mean and median. For the sample mean, it is easy to see that

$$S(x; \bar{X}) = \frac{\bar{x}_{n+1} - \bar{x}_n}{1/(n+1)} = x - \bar{x}_n. \quad (10.9.6)$$

Hence the relative change in the sample mean is a linear function of x . Thus, if x is large, then the change in sample mean is also large. Actually, the change is unbounded in x . Thus the sample mean is quite sensitive to the size of the outlier.

In contrast, consider the sample median in which the sample size n is odd. In this case, the sample median is $\hat{\theta}_{L_1,n} = x_{(r)}$, where $r = (n+1)/2$. When the additional point x is added, the sample size becomes even and the sample median $\hat{\theta}_{L_1,n+1}$ is the average of the middle two order statistics. If x varies between these two order statistics, then there is some change between the $\hat{\theta}_{L_1,n}$ and $\hat{\theta}_{L_1,n+1}$. But once x moves beyond these middle two order statistics, there is no change. Hence $S(x; \hat{\theta}_{L_1,n})$ is a bounded function of x . Therefore, $\hat{\theta}_{L_1,n}$ is much less sensitive to an outlier than the sample mean.

Because the Hodges–Lehmann estimator $\hat{\theta}_{\text{HL}}$, (10.9.4), is also a median, its sensitivity curve is also bounded. Exercise 10.9.2 provides a numerical illustration of these sensitivity curves.

Influence Functions

One problem with the sensitivity curve is its dependence on the sample. In earlier chapters, we compared estimators in terms of their variances which are functions of the underlying distribution. This is the type of comparison we want to make here.

Recall that the location model (10.9.1) is the model of interest, where $F_X(t) = F(t - \theta)$ is the cdf of X and $F(t)$ is the cdf of ε . As discussed in Section 10.1, the parameter θ is a function of the cdf $F_X(x)$. It is convenient, then, to use functional notation $\theta = T(F_X)$, as in Section 10.1. For example, if θ is the mean, then $T(F_X)$ is defined as

$$T(F_X) = \int_{-\infty}^{\infty} x dF_X(x) = \int_{-\infty}^{\infty} xf_X(x) dx, \quad (10.9.7)$$

while if θ is the median, then $T(F_X)$ is defined as

$$T(F_X) = F_X^{-1}\left(\frac{1}{2}\right). \quad (10.9.8)$$

It was shown in Section 10.1 that for a location functional, $T(F_X) = T(F) + \theta$.

Estimating equations (EE) such as those defined in expressions (10.9.2) and (10.9.3) are often quite intuitive, for example, based on likelihood equations or methods such as least squares. On the other hand, functionals are more of an abstract concept. But often the estimating equations naturally lead to the functionals. We outline this next for the mean and median functionals.

Let F_n be the empirical distribution function of the realized sample x_1, x_2, \dots, x_n . That is, F_n is the cdf of the distribution which puts mass n^{-1} on each x_i ; see (10.1.1). Note that we can write the estimating equation (10.9.2), which defines the sample mean as

$$\sum_{i=1}^n (x_i - \theta) \frac{1}{n} = 0. \quad (10.9.9)$$

This is an expectation using the empirical distribution. Since $F_n \rightarrow F_X$ in probability, it would seem that this expectation converges to

$$\int_{-\infty}^{\infty} [x - T(F_X)] f_X(x) dx = 0. \quad (10.9.10)$$

The solution to the above equation is, of course, $T(F_X) = E(X)$.

Likewise, we can write the estimating equation (EE), (10.9.3), which defines the sample median, as

$$\sum_{i=1}^n \text{sgn}(X_i - \theta) \frac{1}{n} = 0. \quad (10.9.11)$$

The corresponding equation for the functional $\theta = T(F_X)$ is the solution of the equation

$$\int_{-\infty}^{\infty} \text{sgn}[y - T(F_X)] f_X(y) dy = 0. \quad (10.9.12)$$

Note that this can be written as

$$0 = - \int_{-\infty}^{T(F_X)} f_X(y) dy + \int_{T(F_X)}^{\infty} f_X(y) dy = -F_X[T(F_X)] + 1 - F_X[T(F_X)].$$

Hence $F_X[T(F_X)] = 1/2$ or $T(F_X) = F_X^{-1}(1/2)$. Thus $T(F_X)$ is the median of the distribution of X .

Now we want to consider how a given functional $T(F_X)$ changes relative to some perturbation. The analog of adding an outlier to $F(t)$ is to consider a **point-mass contamination** of the cdf $F_X(t)$ at a point x . That is, for $\epsilon > 0$, let

$$F_{x,\epsilon}(t) = (1 - \epsilon)F_X(t) + \epsilon\Delta_x(t), \quad (10.9.13)$$

where $\Delta_x(t)$ is the cdf with all its mass at x ; i.e.,

$$\Delta_x(t) = \begin{cases} 0 & t < x \\ 1 & t \geq x. \end{cases} \quad (10.9.14)$$

The cdf $F_{x,\epsilon}(t)$ is a mixture of two distributions. When sampling from it, $(1-\epsilon)100\%$ of the time an observation is drawn from $F_X(t)$, while $\epsilon100\%$ of the time x (an outlier) is drawn. So x has the flavor of the outlier in the sensitivity curve. As Exercise 10.9.4 shows, $F_{x,\epsilon}(t)$ is in an ϵ neighborhood of $F_X(t)$; that is, for all x , $|F_{x,\epsilon}(t) - F_X(t)| \leq \epsilon$. Hence the functional at $F_{x,\epsilon}(t)$ should also be close to $T(F_X)$. The concept for functionals, corresponding to the sensitivity curve, is the function

$$\text{IF}(x; \hat{\theta}) = \lim_{\epsilon \rightarrow 0} \frac{T(F_{x,\epsilon}) - T(F_X)}{\epsilon}, \quad (10.9.15)$$

provided the limit exists. The function $\text{IF}(x; \hat{\theta})$ is called the **influence function** of the estimator $\hat{\theta}$ at x . As the notation suggests, it can be thought of as a derivative of the functional $T(F_{xe})$ with respect to ϵ evaluated at 0, and we often determine it this way. Note that for ϵ small,

$$T(F_{x,\epsilon}) \approx T(F_X) + \epsilon \text{IF}(x; \hat{\theta});$$

hence, the change of the functional due to point-mass contamination is approximately directly proportional to the influence function. We want estimators, whose influence functions are not sensitive to outliers. Further, as mentioned above, for any x , $F_{x,\epsilon}(t)$ is close to $F_X(t)$. Hence, at least, the influence function should be a bounded function of x .

Definition 10.9.1. The estimator $\hat{\theta}$ is said to be **robust** if $|IF(x; \hat{\theta})|$ is bounded for all x .

Hampel (1974) proposed the influence function and discussed its important properties, a few of which we list below. First, however, we determine the influence functions of the sample mean and median.

For the sample mean, recall Section 3.4.1 on mixture distributions. The function $F_{x,\epsilon}(t)$ is the cdf of the random variable $U = I_{1-\epsilon}X + [1 - I_{1-\epsilon}]W$, where X , $I_{1-\epsilon}$, and W are independent random variables, X has cdf $F_X(t)$, W has cdf $\Delta_x(t)$, and $I_{1-\epsilon}$ is $b(1, 1 - \epsilon)$. Hence

$$E(U) = (1 - \epsilon)E(X) + \epsilon E(W) = (1 - \epsilon)E(X) + \epsilon x.$$

Denote the mean functional by $T_\mu(F_X) = E(X)$. In terms of $T_\mu(F)$, we have just shown that

$$T_\mu(F_{x,\epsilon}) = (1 - \epsilon)T_\mu(F_X) + \epsilon x.$$

Therefore,

$$\frac{\partial T_\mu(F_{x,\epsilon})}{\partial \epsilon} = -T_\mu(F) + x.$$

Hence the influence function of the sample mean is

$$IF(x; \bar{X}) = x - \mu, \quad (10.9.16)$$

where $\mu = E(X)$. The influence function of the sample mean is linear in x and, hence, is an unbounded function of x . Therefore, the sample mean is not a robust estimator. Another way to derive the influence function is to differentiate implicitly equation (10.9.10) when this equation is defined for $F_{x,\epsilon}(t)$; see Exercise 10.9.6.

Example 10.9.1 (Influence Function of the Sample Median). In this example, we derive the influence function of the sample median, $\hat{\theta}_{L_1}$. In this case, the functional is $T_\theta(F) = F^{-1}(1/2)$, i.e., the median of F . To determine the influence function, we first need to determine the functional at the contaminated cdf $F_{x,\epsilon}(t)$, i.e., determine $F_{x,\epsilon}^{-1}(1/2)$. As shown in Exercise 10.9.8, the inverse of the cdf $F_{x,\epsilon}(t)$ is given by

$$F_{x,\epsilon}^{-1}(u) = \begin{cases} F^{-1}\left(\frac{u}{1-\epsilon}\right) & u < F(x) \\ F^{-1}\left(\frac{u-\epsilon}{1-\epsilon}\right) & u \geq F(x), \end{cases} \quad (10.9.17)$$

for $0 < u < 1$. Hence, letting $u = 1/2$, we get

$$T_\theta(F_{x,\epsilon}) = F_{x,\epsilon}^{-1}(1/2) = \begin{cases} F_X^{-1}\left(\frac{1/2}{1-\epsilon}\right) & F_X^{-1}\left(\frac{1}{2}\right) < x \\ F_X^{-1}\left(\frac{(1/2)-\epsilon}{1-\epsilon}\right) & F_X^{-1}\left(\frac{1}{2}\right) > x. \end{cases} \quad (10.9.18)$$

Based on (10.9.18) the partial derivative of $F_{x,\epsilon}^{-1}(1/2)$ with respect to ϵ is seen to be

$$\frac{\partial T_\theta(F_{x,\epsilon})}{\partial \epsilon} = \begin{cases} \frac{(1/2)(1-\epsilon)^{-2}}{f_X[F_X^{-1}((1/2)/(1-\epsilon))]} & F_X^{-1}\left(\frac{1}{2}\right) < x \\ \frac{(-1/2)(1-\epsilon)^{-2}}{f_X[F_X^{-1}((1/2)-\epsilon)/\{1-\epsilon\})]} & F_X^{-1}\left(\frac{1}{2}\right) > x. \end{cases} \quad (10.9.19)$$

Evaluating this partial derivative at $\epsilon = 0$, we arrive at the influence function of the median:

$$\text{IF}(x; \hat{\theta}_{L_1}) = \begin{cases} \frac{1}{2f_X(\theta)} & \theta < x \\ \frac{-1}{2f_X(\theta)} & \theta > x \end{cases} = \frac{\text{sgn}(x - \theta)}{2f(\theta)}, \quad (10.9.20)$$

where θ is the median of F_X . Because this influence function is bounded, the sample median is a robust estimator. ■

As derived on p. 46 of Hettmansperger and McKean (2011), the influence function of the Hodges–Lehmann estimator, $\hat{\theta}_{\text{HL}}$, at the point x is given by:

$$\text{IF}(x; \hat{\theta}_{\text{HL}}) = \frac{F_X(x) - 1/2}{\int_{-\infty}^{\infty} f_X^2(t) dt}. \quad (10.9.21)$$

Since a cdf is bounded, the Hodges–Lehmann estimator is robust.

We now list three useful properties of the influence function of an estimator. Note that for the sample mean, $E[\text{IF}(X; \bar{X})] = E[X] - \mu = 0$. This is true in general. Let $\text{IF}(x) = \text{IF}(x; \hat{\theta})$ denote the influence function of the estimator $\hat{\theta}$ with functional $\theta = T(F_X)$. Then

$$E[\text{IF}(X)] = 0, \quad (10.9.22)$$

provided expectations exist; see Huber (1981) for a discussion. Hence, for the second property, we have

$$\text{Var}[\text{IF}(X)] = E[\text{IF}^2(X)], \quad (10.9.23)$$

provided the squared expectation exists. A third property of the influence function is the asymptotic result

$$\sqrt{n}[\hat{\theta} - \theta] = \frac{1}{\sqrt{n}} \sum_{i=1}^n \text{IF}(X_i) + o_p(1). \quad (10.9.24)$$

Assume that the variance (10.9.23) exists, then because $\text{IF}(X_1), \dots, \text{IF}(X_n)$ are iid with finite variance, the simple Central Limit Theorem and (10.9.24) imply that

$$\sqrt{n}[\hat{\theta} - \theta] \xrightarrow{D} N(0, E[\text{IF}^2(X)]). \quad (10.9.25)$$

Thus we can obtain the asymptotic distribution of the estimator from its influence function. Under general conditions, expression (10.9.24) holds, but often the verification of the conditions is difficult and the asymptotic distribution can be obtained more easily in another way; see Huber (1981) for a discussion. In this chapter, though, we use (10.9.24) to obtain asymptotic distributions of estimators. Suppose (10.9.24) holds for the estimators $\hat{\theta}_1$ and $\hat{\theta}_2$, which are both estimators of the same functional, say, θ . Then, letting IF_i denote the influence function of $\hat{\theta}_i$, $i = 1, 2$, we can express the asymptotic relative efficiency between the two estimators as

$$\text{ARE}(\hat{\theta}_1, \hat{\theta}_2) = \frac{E[\text{IF}_2^2(X)]}{E[\text{IF}_1^2(X)]}. \quad (10.9.26)$$

As an example, we consider the sample median.

Example 10.9.2 (Asymptotic Distribution of the Sample Median). The influence function for the sample median $\hat{\theta}_{L_1}$ is given by (10.9.20). Since $E[\text{sgn}^2(X - \theta)] = 1$, by expression (10.9.25) the asymptotic distribution of the sample median is

$$\sqrt{n}[\hat{\theta} - \theta] \xrightarrow{D} N(0, [2f_X(\theta)]^{-2}),$$

where θ is the median of the pdf $f_X(t)$. This agrees with the result given in Section 10.2. ■

Breakdown Point of an Estimator

The influence function of an estimator measures the sensitivity of an estimator to a single outlier, sometimes called the *local sensitivity* of the estimator. We next discuss a measure of *global sensitivity* of an estimator. That is, what proportion of outliers can an estimator tolerate without completely breaking down?

To be precise, let $\mathbf{x}' = (x_1, x_2, \dots, x_n)$ be a realization of a sample. Suppose we corrupt m points of this sample by replacing x_1, \dots, x_m by x_1^*, \dots, x_m^* , where these points are large outliers. Let $\mathbf{x}_m = (x_1^*, \dots, x_m^*, x_{m+1}, \dots, x_n)$ denote the corrupted sample. Define the bias of the estimator upon corrupting m data points to be

$$\text{bias}(m, \mathbf{x}_n, \hat{\theta}) = \sup |\hat{\theta}(\mathbf{x}_m) - \hat{\theta}(\mathbf{x}_n)|, \quad (10.9.27)$$

where the sup is taken over all possible corrupted samples \mathbf{x}_m . If this bias is infinite, we say that the estimator has **broken down**. The smallest proportion of corruption an estimator can tolerate until its breakdown is called its *finite sample breakdown point*. More precisely, if

$$\epsilon_n^* = \min_m \{m/n : \text{bias}(m, \mathbf{x}_n, \hat{\theta}) = \infty\}, \quad (10.9.28)$$

then ϵ_n^* is called the **finite sample breakdown point** of $\hat{\theta}$. If the limit

$$\epsilon_n^* \rightarrow \epsilon^* \quad (10.9.29)$$

exists, we call ϵ^* the **breakdown point** of $\hat{\theta}$.

To determine the breakdown point of the sample mean, suppose we corrupt one data point, say, without loss of generality, the first data point. The corrupted sample is then $\mathbf{x}' = (x_1^*, x_2, \dots, x_n)$. Denote the sample mean of the corrupted sample by \bar{x}^* . Then it is easy to see that

$$\bar{x}^* - \bar{x} = \frac{1}{n}(x_1^* - x_1).$$

Hence $\text{bias}(1, \mathbf{x}_n, \bar{x})$ is a linear function of x_1^* and can be made as large (in absolute value) as desired by taking x_1^* large (in absolute value). Therefore, the finite sample breakdown of the sample mean is $1/n$. Because this goes to 0 as $n \rightarrow \infty$, the breakdown point of the sample mean is 0.

Example 10.9.3 (Breakdown Value of the Sample Median). Next consider the sample median. Let $\mathbf{x}_n = (x_1, x_2, \dots, x_n)$ be a realization of a random sample. If the sample size is $n = 2k$, then it is easy to see that in a corrupted sample \mathbf{x}_n when $x_{(k)}$ tends to $-\infty$, the median also tends to $-\infty$. Hence the breakdown value of the sample median is k/n , which tends to 0.5. By a similar argument, when the sample size is $n = 2k + 1$, the breakdown value is $(k + 1)/n$ and it also tends to 0.5 as the sample size increases. Hence we say that the sample median is a 50% breakdown estimate. For a location model, 50% breakdown is the highest possible breakdown point for an estimate. Thus the median achieves the highest possible breakdown point. ■

In Exercise 10.9.10, the reader is asked to show that the Hodges–Lehmann estimate has the breakdown point of 0.29.

10.9.2 Linear Model

In Sections 9.6 and 10.7, respectively, we presented the least squares (LS) procedure and a rank-based (Wilcoxon) procedure for fitting simple linear models. In this section, we briefly compare these procedures in terms of their robustness properties.

Recall that the simple linear model is given by

$$Y_i = \alpha + \beta x_{ci} + \varepsilon_i, \quad i = 1, 2, \dots, n, \quad (10.9.30)$$

where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n$ are continuous random variable that are iid. In this model, we have centered the regression variables; that is, $x_{ci} = x_i - \bar{x}$, where x_1, x_2, \dots, x_n are considered fixed. The parameter of interest in this section is the slope parameter β , the expected change (provided expectations exist) when the regression variable increases by one unit. The centering of the xs allows us to consider the slope parameter by itself. The results we present are invariant to the intercept parameter α . Estimates of α are discussed at the end of this section. With this in mind, define the random variable e_i to be $\varepsilon_i + \alpha$. Then we can write the model as

$$Y_i = \beta x_{ci} + e_i, \quad i = 1, 2, \dots, n, \quad (10.9.31)$$

where e_1, e_2, \dots, e_n are iid with continuous cdf $F(x)$ and pdf $f(x)$. We often refer to the support of Y as the **Y -space**. Likewise, we refer to the range of X as the **X -space**. The **X -space** is often referred to as the **factor space**.

Least Squares and Wilcoxon Procedures

The first procedure is *least squares* (LS). The estimating equation for β is given by expression (9.6.4) of Chapter 9. Using the fact that $\sum_i x_{ci} = 0$, this equation can be reexpressed as

$$\sum_{i=1}^n (Y_i - x_{ci}\beta)x_{ci} = 0. \quad (10.9.32)$$

This is the estimating equation (EE) for the LS estimator of β , which we use in this section. It is often called the **normal equation**. It is easy to see that the LS

estimator is

$$\hat{\beta}_{\text{LS}} = \frac{\sum_{i=1}^n x_{ci} Y_i}{\sum_{i=1}^n x_{ci}^2}, \quad (10.9.33)$$

which agrees with expression (9.6.5) of Chapter 9. The geometry of the LS estimator is discussed in Remark 9.6.2.

For our second procedure, we consider the estimate of slope discussed in Section 10.7. This is a rank-based estimate based on an arbitrary score function. In this section, we restrict our discussion to the linear (Wilcoxon) scores; i.e., the score function is given by $\varphi_W(u) = \sqrt{12}[u - (1/2)]$, where the subscript W denotes the Wilcoxon score function. The estimating equation of the rank-based estimator of β is given by expression (10.7.8), which for the Wilcoxon score function is

$$\sum_{i=1}^n a_W(R(Y_i - x_{ci}\beta))x_{ci} = 0, \quad (10.9.34)$$

where $a_W(i) = \varphi_W[i/(n+1)]$. This equation is the analog of the LS normal equation. See Exercise 10.9.12 for a geometric interpretation.

Influence Functions

To determine the robustness properties of these procedures, first consider a probability model corresponding to Model (10.9.31), in which X , in addition to Y , is a random variable. Assume that the random vector (X, Y) has joint cdf and pdf, $H(x, y)$ and $h(x, y)$, respectively, and satisfies

$$Y = \beta X + e, \quad (10.9.35)$$

where the random variable e has cdf and pdf $F(t)$ and $f(t)$, respectively, and e and X are independent. Since we have centered the xs , we also assume that $E(X) = 0$. As Exercise 10.9.13 shows,

$$P(Y \leq t | X = x) = F(t - \beta x), \quad (10.9.36)$$

and, hence, Y and X are independent if and only if $\beta = 0$.

The functional for the LS estimator easily follows from the LS normal equation (10.9.32). Let H_n denote the empirical cdf of the pairs $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$; that is, H_n is the cdf corresponding to the discrete distribution, which puts probability (mass) of $1/n$ on each point (x_i, y_i) . Then the LS estimating equation, (10.9.32), can be expressed as an expectation with respect to this distribution as

$$\sum_{i=1}^n (y_i - x_{ci}\beta)x_{ci} \frac{1}{n} = 0. \quad (10.9.37)$$

For the probability model, (10.9.35), it follows that the functional $T_{\text{LS}}(H)$ corresponding to the LS estimate is the solution to the equation

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [y - T_{\text{LS}}(H)x]xh(x, y) dx dy = 0. \quad (10.9.38)$$

To obtain the functional corresponding to the Wilcoxon estimate, recall the association between the ranks and the empirical cdf; see (10.5.14). For Wilcoxon scores, we have

$$a_W(R(Y_i - x_{ci}\beta)) = \varphi_W\left[\frac{n}{n+1}F_n(Y_i - x_{ci}\beta)\right]. \quad (10.9.39)$$

Based on the Wilcoxon estimating equations, (10.9.34), and expression (10.9.39), the functional $T_W(H)$ corresponding to the Wilcoxon estimate satisfies the equation

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \varphi_W\{F[y - T_W(H)x]\} x h(x, y) dx dy = 0. \quad (10.9.40)$$

We next derive the influence functions of the LS and Wilcoxon estimators of β . In regression models, we are concerned about the influence of outliers in both the Y - and X -spaces. Consider then a point-mass distribution with all its mass at the point (x_0, y_0) , and let $\Delta_{(x_0, y_0)}(x, y)$ denote the corresponding cdf. Let ϵ denote the probability of sampling from this contaminating distribution, where $0 < \epsilon < 1$. Hence, consider the contaminated distribution with cdf

$$H_\epsilon(x, y) = (1 - \epsilon)H(x, y) + \epsilon\Delta_{(x_0, y_0)}(x, y). \quad (10.9.41)$$

Because the differential is a linear operator, we have

$$dH_\epsilon(x, y) = (1 - \epsilon)dH(x, y) + \epsilon d\Delta_{(x_0, y_0)}(x, y), \quad (10.9.42)$$

where $dH(x, y) = h(x, y) dx dy$; that is, d corresponds to the second mixed partial $\partial^2/\partial x \partial y$.

By (10.9.38), the LS functional T_ϵ at the cdf $H_\epsilon(x, y)$ satisfies the equation

$$0 = (1 - \epsilon) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x(y - xT_\epsilon) h(x, y) dx dy + \epsilon \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x(y - xT_\epsilon) d\Delta_{(x_0, y_0)}(x, y). \quad (10.9.43)$$

To find the partial derivative of T_ϵ with respect to ϵ , we simply implicitly differentiate expression (10.9.43) with respect to ϵ , which yields

$$\begin{aligned} 0 &= - \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x(y - T_\epsilon x) h(x, y) dx dy \\ &\quad + (1 - \epsilon) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x(-x) \frac{\partial T_\epsilon}{\partial \epsilon} h(x, y) dx dy \\ &\quad + \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x(y - xT_\epsilon) d\Delta_{(x_0, y_0)}(x, y) + \epsilon B, \end{aligned} \quad (10.9.44)$$

where the expression for B is not needed since we are evaluating this partial at $\epsilon = 0$. Notice that at $\epsilon = 0$, $y - T_\epsilon x = y - Tx = y - \beta x$. Hence, at $\epsilon = 0$, the first expression on the right side of (10.9.44) is 0, while the second expression becomes $-E(X^2)(\partial T/\partial \epsilon)$, where the partial is evaluated at 0. Finally, the third expression is the expected value of the point-mass distribution $\Delta_{(x_0, y_0)}$, which is, of course,

$x_0(y_0 - \beta x_0)$. Therefore, solving for the partial $\partial T_\epsilon / \partial \epsilon$ and evaluating at $\epsilon = 0$, we see that the influence function of the LS estimator is given by

$$\text{IF}(x_0, y_0; \hat{\beta}_{\text{LS}}) = \frac{(y_0 - \beta x_0)x_0}{E(X^2)}. \quad (10.9.45)$$

Note that the influence function is unbounded in both the Y - and X -spaces. Hence the LS estimator is unduly sensitive to outliers in both spaces. It is not robust.

Based on expression (10.9.40), the Wilcoxon functional at the contaminated distribution satisfies the equation

$$\begin{aligned} 0 &= (1 - \epsilon) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \varphi_W[F(y - xT_\epsilon)] h(x, y) dx dy \\ &\quad + \epsilon \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \varphi_W[F(y - xT_\epsilon)] d\Delta_{(x_0, y_0)}(x, y) \end{aligned} \quad (10.9.46)$$

[technically, the cdf F should be replaced by the actual cdf of the residual, but the result is the same; see page 477 of Hettmansperger and McKean (2011)]. Proceeding to implicitly differentiate this expression with respect to ϵ , we obtain

$$\begin{aligned} 0 &= - \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \varphi_W[F(y - xT_\epsilon)] h(x, y) dx dy \\ &\quad + (1 - \epsilon) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \varphi'_W[F(y - T_\epsilon x)] f(y - T_\epsilon x)(-x) \frac{\partial T_\epsilon}{\partial \epsilon} h(x, y) dx dy \\ &\quad + \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x \varphi_W[F(y - xT_\epsilon)] d\Delta_{(x_0, y_0)}(x, y) + \epsilon B, \end{aligned} \quad (10.9.47)$$

where the expression for B is not needed since we are evaluating this partial at $\epsilon = 0$. When $\epsilon = 0$, then $Y - TX = e$ and the random variables e and X are independent. Hence, upon setting $\epsilon = 0$, expression (10.9.47) simplifies to

$$0 = -E[\varphi'_W(F(e))f(e)]E(X^2) \left. \frac{\partial T_\epsilon}{\partial \epsilon} \right|_{\epsilon=0} + \varphi_W[F(y_0 - x_0 \beta)]x_0. \quad (10.9.48)$$

Since $\varphi'(u) = \sqrt{12}$, we finally obtain, as the influence function of the Wilcoxon estimator,

$$\text{IF}(x_0, y_0; \hat{\beta}_W) = \frac{\tau \varphi_W[F(y_0 - \beta x_0)]x_0}{E(X^2)}, \quad (10.9.49)$$

where $\tau = 1/[\sqrt{12} \int f^2(e) de]$. Note that the influence function is bounded in the Y -space, but it is unbounded in the X -space. Thus, unlike the LS estimator, the Wilcoxon estimator is robust against outliers in the Y -space, but like the LS estimator, it is sensitive to outliers in the X -space. Weighted versions of the Wilcoxon estimator, though, have bounded influence in both the Y - and X -spaces; see the discussion of the HBR estimator in Chapter 3 of Hettmansperger and McKean (2011). Exercises 10.9.18 and 10.9.19 asks for derivations, respectively, of the asymptotic distributions of the LS and Wilcoxon estimators, using their influence functions.

Breakdown Points

Breakdown for the regression model is based on the corruption of the sample in Model (10.9.31), that is, the sample $(x_{c1}, Y_1), \dots, (x_{cn}, Y_n)$. Based on the influence functions for both the LS and Wilcoxon estimators, it is clear that corrupting one x_i breaks down both estimators. This is shown in Exercise 10.9.14. Hence the breakdown point of each estimator is 0. The HBR estimator (weighted version of the Wilcoxon estimator) has bounded influence in both spaces and can achieve 50% breakdown; see Chang et al. (1999) and Hettmansperger and McKean (2011).

Intercept

In practice, the linear model usually contains an intercept parameter; that is, the model is given by (10.9.30) with intercept parameter α . Notice that α is a location parameter of the random variables $Y_i - \beta x_{ci}$. This suggests an estimate of location on the residuals $Y_i - \hat{\beta} x_{ci}$. For LS, we take the sample mean of the residuals; i.e.,

$$\hat{\alpha}_{\text{LS}} = n^{-1} \sum_{i=1}^n (Y_i - \hat{\beta}_{\text{LS}} x_{ci}) = \bar{Y}, \quad (10.9.50)$$

because the x_{cis} are centered. For the Wilcoxon fit, several choices seem appropriate. We use the median of the Wilcoxon residuals. That is, let

$$\hat{\alpha}_W = \text{med}_{1 \leq i \leq n} \{Y_i - \hat{\beta}_W x_{ci}\}. \quad (10.9.51)$$

For the Wilcoxon fit of the regression model, computation is discussed in Remark 10.7.1. As there, we recommend the CRAN package **Rfit** developed by Kloke and McKean (2014). The R package¹ **hbrrfit** computes the high breakdown HBR fit.

EXERCISES

10.9.1. Consider the location model as defined in expression (10.9.1). Let

$$\hat{\theta} = \text{Argmin}_{\theta} \|\mathbf{X} - \theta \mathbf{1}\|_{\text{LS}}^2,$$

where $\|\cdot\|_{\text{LS}}^2$ is the square of the Euclidean norm. Show that $\hat{\theta} = \bar{x}$.

10.9.2. Obtain the sensitivity curves for the sample mean, the sample median and the Hodges–Lehmann estimator for the following data set. Evaluate the curves at the values -300 to 300 in increments of 10 and graph the curves on the same plot. Compare the sensitivity curves.

$$\begin{array}{cccccccc} -9 & 58 & 12 & -1 & -37 & 0 & 11 & 21 \\ 18 & -24 & -4 & -53 & -9 & 9 & 8 \end{array}$$

Note that the R command `wilcox.test(x, conf.int=T)$est` computes the Hodges–Lehmann estimate for the R vector `x`.

¹Downloadable at <https://github.com/kloke/>

10.9.3. Consider the influence function for the Hodges–Lehmann estimator given in expression (10.9.21). Show for it that property (10.9.22) is true. Next, evaluate expression (10.9.23) and, hence, obtain the asymptotic distribution of the estimator as given in expression (10.9.25). Does it agree with the result derived in Section 10.3?

10.9.4. Let $F_{x,\epsilon}(t)$ be the point-mass contaminated cdf given in expression (10.9.13). Show that

$$|F_{x,\epsilon}(t) - F_X(t)| \leq \epsilon,$$

for all t .

10.9.5. Suppose X is a random variable with mean 0 and variance σ^2 . Recall that the function $F_{x,\epsilon}(t)$ is the cdf of the random variable $U = I_{1-\epsilon}X + [1 - I_{1-\epsilon}]W$, where X , $I_{1-\epsilon}$, and W are independent random variables, X has cdf $F_X(t)$, W has cdf $\Delta_x(t)$, and $I_{1-\epsilon}$ has a binomial(1, 1 – ϵ) distribution. Define the functional $\text{Var}(F_X) = \text{Var}(X) = \sigma^2$. Note that the functional at the contaminated cdf $F_{x,\epsilon}(t)$ has the variance of the random variable $U = I_{1-\epsilon}X + [1 - I_{1-\epsilon}]W$. To derive the influence function of the variance, perform the following steps:

- (a) Show that $E(U) = \epsilon x$.
- (b) Show that $\text{Var}(U) = (1 - \epsilon)\sigma^2 + \epsilon x^2 - \epsilon^2 x^2$.
- (c) Obtain the partial derivative of the right side of this equation with respect to ϵ . This is the influence function.

Hint: Because $I_{1-\epsilon}$ is a Bernoulli random variable, $I_{1-\epsilon}^2 = I_{1-\epsilon}$. Why?

10.9.6. Often influence functions are derived by differentiating implicitly the defining equation for the functional at the contaminated cdf $F_{x,\epsilon}(t)$, (10.9.13). Consider the mean functional with the defining equation (10.9.10). Using the linearity of the differential, first show that the defining equation at the cdf $F_{x,\epsilon}(t)$ can be expressed as

$$\begin{aligned} 0 = \int_{-\infty}^{\infty} [t - T(F_{x,\epsilon})] dF_{x,\epsilon}(t) &= (1 - \epsilon) \int_{-\infty}^{\infty} [t - T(F_{x,\epsilon})] f_X(t) dt \\ &\quad + \epsilon \int_{-\infty}^{\infty} [t - T(F_{x,\epsilon})] d\Delta(t). \end{aligned} \quad (10.9.52)$$

Recall that we want $\partial T(F_{x,\epsilon})/\partial \epsilon$. Obtain this by implicitly differentiating the above equation with respect to ϵ .

10.9.7. In Exercise 10.9.5, the influence function of the variance functional was derived directly. Assuming that the mean of X is 0, note that the variance functional, $V(F_X)$, also solves the equation

$$0 = \int_{-\infty}^{\infty} [t^2 - V(F_X)] f_X(t) dt.$$

- (a) Determine the natural estimator of the variance by writing the defining equation at the empirical cdf $F_n(t)$, for $X_1 - \bar{X}, \dots, X_n - \bar{X}$ iid with cdf $F_X(t)$, and solving for $V(F_n)$.
- (b) As in Exercise 10.9.6, write the defining equation for the variance functional at the contaminated cdf $F_{x,\epsilon}(t)$.
- (c) Then derive the influence function by implicit differentiation of the defining equation in part (b).

10.9.8. Show that the inverse of the cdf $F_{x,\epsilon}(t)$ given in expression (10.9.17) is correct.

10.9.9. Let $\text{IF}(x)$ be the influence function of the sample median given by (10.9.20). Determine $E[\text{IF}(X)]$ and $\text{Var}[\text{IF}(X)]$.

10.9.10. Let x_1, x_2, \dots, x_n be a realization of a random sample. Consider the Hodges–Lehmann estimate of location given in expression (10.9.4). Show that the breakdown point of this estimate is 0.29.

Hint: Suppose we corrupt m data points. We need to determine the value of m that results in corruption of one-half of the Walsh averages. Show that the corruption of m data points leads to

$$p(m) = m + \binom{m}{2} + m(n-m)$$

corrupted Walsh averages. Hence the finite sample breakdown point is the “correct” solution of the quadratic equation $p(m) = n(n+1)/4$.

10.9.11. For any $n \times 1$ vector \mathbf{v} , define the function $\|\mathbf{v}\|_W$ by

$$\|\mathbf{v}\|_W = \sum_{i=1}^n a_W(R(v_i))v_i, \quad (10.9.53)$$

where $R(v_i)$ denotes the rank of v_i among v_1, \dots, v_n and the Wilcoxon scores are given by $a_W(i) = \varphi_W[i/(n+1)]$ for $\varphi_W(u) = \sqrt{12}[u - (1/2)]$. By using the correspondence between order statistics and ranks, show that

$$\|\mathbf{v}\|_W = \sum_{i=1}^n a(i)v_{(i)}, \quad (10.9.54)$$

where $v_{(1)} \leq \dots \leq v_{(n)}$ are the ordered values of v_1, \dots, v_n . Then, by establishing the following properties, show that the function (10.9.53) is a **pseudo-norm** on R^n .

- (a) $\|\mathbf{v}\|_W \geq 0$ and $\|\mathbf{v}\|_W = 0$ if and only if $v_1 = v_2 = \dots = v_n$.

Hint: First, because the scores $a(i)$ sum to 0, show that

$$\sum_{i=1}^n a(i)v_{(i)} = \sum_{i < j} a(i)[v_{(i)} - v_{(j)}] + \sum_{i > j} a(i)[v_{(i)} - v_{(j)}],$$

where j is the largest integer in the set $\{1, 2, \dots, n\}$ such that $a(j) < 0$.

- (b) $\|c\mathbf{v}\|_W = |c|\|\mathbf{v}\|_W$, for all $c \in R$.
- (c) $\|\mathbf{v} + \mathbf{w}\|_W \leq \|\mathbf{v}\|_W + \|\mathbf{w}\|_W$, for all $\mathbf{v}, \mathbf{w} \in R^n$.

Hint: Determine the permutations, say, i_k and j_k of the integers $\{1, 2, \dots, n\}$, which maximize $\sum_{k=1}^n c_{i_k} d_{j_k}$ for the two sets of numbers $\{c_1, \dots, c_n\}$ and $\{d_1, \dots, d_n\}$.

10.9.12. Remark 9.6.2 discusses the geometry of the LS estimate of β . There is an analogous geometry for the Wilcoxon estimate. Using the norm $\|\cdot\|_W$ defined in expression (10.9.53) of the last exercise, let

$$\hat{\beta}^* = \operatorname{Argmin} \|\mathbf{Y} - \mathbf{X}_c \beta\|_W,$$

where $\mathbf{Y}' = (Y_1, \dots, Y_n)$ and $\mathbf{X}'_c = (x_{c1}, \dots, x_{cn})$. Thus $\hat{\beta}^*$ minimizes the distance between \mathbf{Y} and the space spanned by the vector \mathbf{X}_c .

- (a) Using expression (10.9.54), show that $\hat{\beta}^*$ satisfies the Wilcoxon estimating equation (10.9.34). That is, $\hat{\beta}^* = \hat{\beta}_W$.
- (b) Let $\hat{\mathbf{Y}}_W = \mathbf{X}_c \hat{\beta}_W$ and $\mathbf{Y} - \hat{\mathbf{Y}}_W$ denote the Wilcoxon vectors of fitted values and residuals, respectively. Sketch a figure analogous to the LS Figure 9.6.3 but with these vectors on it. Note that your figure may not contain a right angle.
- (c) For the Wilcoxon regression procedure, determine a vector (not $\mathbf{0}$) that is orthogonal to $\hat{\mathbf{Y}}_W$.

10.9.13. For Model (10.9.35), show that equation (10.9.36) holds. Then show that Y and X are independent if and only if $\beta = 0$. Hence independence is based on the value of a parameter. This is a case where normality is not necessary to have this independence property.

10.9.14. Consider the telephone data discussed in Example 10.7.2 and given in the rda-file `telephone.rda`. It is easily seen in Figure 10.7.1 that there are seven outliers in the Y -space. Based on the estimates discussed in this example, the Wilcoxon estimate of slope is robust to these outliers, while the LS estimate is highly sensitive to them.

- (a) For this data set, change the last value of x from 73 to 173. Notice the drastic change in the LS fit.
- (b) Obtain the Wilcoxon estimate for the changed data in part (a). Notice that it has a drastic change also. To obtain the Wilcoxon fit, see Remark 10.7.1 on computation.
- (c) Using the Wilcoxon estimates of Example 10.7.2, change the the value of Y at $x = 173$ to the predicted value of Y based on the Wilcoxon estimates of Example 10.7.2. Note that this point is a “good” point at the outlying x ; that is, it fits the model. Now determine the Wilcoxon and LS estimates. Comment on them.

10.9.15. For the pseudo-norm $\|\mathbf{v}\|_W$ defined in expression (10.9.53), establish the identity

$$\|\mathbf{v}\|_W = \frac{\sqrt{3}}{2(n+1)} \sum_{i=1}^n \sum_{j=1}^n |v_i - v_j|, \quad (10.9.55)$$

for all $\mathbf{v} \in R^n$. Thus we have shown that

$$\widehat{\beta}_W = \operatorname{Argmin} \sum_{i=1}^n \sum_{j=1}^n |(y_i - y_j) - \beta(x_{ci} - x_{cj})|. \quad (10.9.56)$$

Note that the formulation of $\widehat{\beta}_W$ given in expression (10.9.56) allows an easy way to compute the Wilcoxon estimate of slope by using an L_1 (least absolute deviations) routine. Terpstra and McKean (2005) used this identity, (10.9.55), to develop R functions for the computation of the Wilcoxon fit.

10.9.16. Suppose the random variable e has cdf $F(t)$. Let $\varphi(u) = \sqrt{12}[u - (1/2)]$, $0 < u < 1$, denote the Wilcoxon score function.

- (a) Show that the random variable $\varphi[F(e_i)]$ has mean 0 and variance 1.
- (b) Investigate the mean and variance of $\varphi[F(e_i)]$ for any score function $\varphi(u)$ which satisfies $\int_0^1 \varphi(u) du = 0$ and $\int_0^1 \varphi^2(u) du = 1$.

10.9.17. In the derivation of the influence function, we assumed that x was random. For inference, though, we consider the case that x is given. In this case, the variance of X , $E(X^2)$, which is found in the influence function, is replaced by its estimate, namely, $n^{-1} \sum_{i=1}^n x_{ci}^2$. With this in mind, use the influence function of the LS estimator of β to derive the asymptotic distribution of the LS estimator; see the discussion around expression (10.9.24). Show that it agrees with the exact distribution of the LS estimator given in expression (9.6.9) under the assumption that the errors have a normal distribution.

10.9.18. As in the last problem, use the influence function of the Wilcoxon estimator of β to derive the asymptotic distribution of the Wilcoxon estimator. For Wilcoxon scores, show that it agrees with expression (10.7.14).

10.9.19. Use the results of the last two exercises to find the asymptotic relative efficiency (ARE) between the Wilcoxon and LS estimators of β .

Chapter 11

Bayesian Statistics

11.1 Bayesian Procedures

To understand the Bayesian inference, let us review Bayes Theorem, (1.4.3), in a situation in which we are trying to determine something about a parameter of a distribution. Suppose we have a Poisson distribution with parameter $\theta > 0$, and we know that the parameter is equal to either $\theta = 2$ or $\theta = 3$. In Bayesian inference, the parameter is treated as a random variable Θ . Suppose, for this example, we assign subjective **prior** probabilities of $P(\Theta = 2) = \frac{1}{3}$ and $P(\Theta = 3) = \frac{2}{3}$ to the two possible values. These subjective probabilities are based upon past experiences, and it might be unrealistic that Θ can only take one of two values, instead of a continuous $\theta > 0$ (we address this immediately after this introductory illustration). Now suppose a random sample of size $n = 2$ results in the observations $x_1 = 2$, $x_2 = 4$. Given these data, what are the **posterior** probabilities of $\Theta = 2$ and $\Theta = 3$? By Bayes Theorem, we have

$$\begin{aligned} & P(\Theta = 2|X_1 = 2, X_2 = 4) \\ &= \frac{P(\Theta = 2 \text{ and } X_1 = 2, X_2 = 4)}{P(X_1 = 2, X_2 = 4|\Theta = 2)P(\Theta = 2) + P(X_1 = 2, X_2 = 4|\Theta = 3)P(\Theta = 3)} \\ &= \frac{\left(\frac{1}{3}\right) \frac{e^{-2}2^2}{2!} \frac{e^{-2}2^4}{4!}}{\left(\frac{1}{3}\right) \frac{e^{-2}2^2}{2!} \frac{e^{-2}2^4}{4!} + \left(\frac{2}{3}\right) \frac{e^{-3}3^2}{2!} \frac{e^{-3}3^4}{4!}} = 0.245. \end{aligned}$$

Similarly,

$$P(\Theta = 3|X_1 = 2, X_2 = 4) = 1 - 0.245 = 0.755.$$

That is, with the observations $x_1 = 2, x_2 = 4$, the posterior probability of $\Theta = 2$ was smaller than the prior probability of $\Theta = 2$. Similarly, the posterior probability of $\Theta = 3$ was greater than the corresponding prior. That is, the observations $x_1 = 2, x_2 = 4$ seemed to favor $\Theta = 3$ more than $\Theta = 2$; and that seems to agree with our intuition as $\bar{x} = 3$. Now let us address in general a more realistic situation in which we place a prior pdf $h(\theta)$ on a support that is a continuum.

11.1.1 Prior and Posterior Distributions

We now describe the Bayesian approach to the problem of estimation. This approach takes into account any prior knowledge of the experiment that the statistician has and it is one application of a principle of statistical inference that may be called **Bayesian statistics**. Consider a random variable X that has a distribution of probability that depends upon the symbol θ , where θ is an element of a well-defined set Ω . For example, if the symbol θ is the mean of a normal distribution, Ω may be the real line. We have previously looked upon θ as being a parameter, albeit an unknown parameter. Let us now introduce a random variable Θ that has a distribution of probability over the set Ω ; and just as we look upon x as a possible value of the random variable X , we now look upon θ as a possible value of the random variable Θ . Thus, the distribution of X depends upon θ , an experimental value of the random variable Θ . We denote the pdf of Θ by $h(\theta)$ and we take $h(\theta) = 0$ when θ is not an element of Ω . The pdf $h(\theta)$ is called the **prior** pdf of Θ . Moreover, we now denote the pdf of X by $f(x|\theta)$ since we think of it as a conditional pdf of X , given $\Theta = \theta$. For clarity in this chapter, we use the following summary of this model:

$$\begin{aligned} X|\theta &\sim f(x|\theta) \\ \Theta &\sim h(\theta). \end{aligned} \quad (11.1.1)$$

Suppose that X_1, X_2, \dots, X_n is a random sample from the conditional distribution of X given $\Theta = \theta$ with pdf $f(x|\theta)$. Vector notation is convenient in this chapter. Let $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ and $\mathbf{x}' = (x_1, x_2, \dots, x_n)$. Thus we can write the joint conditional pdf of \mathbf{X} , given $\Theta = \theta$, as

$$L(\mathbf{x} | \theta) = f(x_1|\theta)f(x_2|\theta)\cdots f(x_n|\theta). \quad (11.1.2)$$

Thus the joint pdf of \mathbf{X} and Θ is

$$g(\mathbf{x}, \theta) = L(\mathbf{x} | \theta)h(\theta). \quad (11.1.3)$$

If Θ is a random variable of the continuous type, the joint marginal pdf of \mathbf{X} is given by

$$g_1(\mathbf{x}) = \int_{-\infty}^{\infty} g(\mathbf{x}, \theta) d\theta. \quad (11.1.4)$$

If Θ is a random variable of the discrete type, integration would be replaced by summation. In either case, the conditional pdf of Θ , given the sample \mathbf{X} , is

$$k(\theta|\mathbf{x}) = \frac{g(\mathbf{x}, \theta)}{g_1(\mathbf{x})} = \frac{L(\mathbf{x} | \theta)h(\theta)}{g_1(\mathbf{x})}. \quad (11.1.5)$$

The distribution defined by this conditional pdf is called the **posterior distribution** and (11.1.5) is called the **posterior pdf**. The prior distribution reflects the subjective belief of Θ before the sample is drawn, while the posterior distribution is the conditional distribution of Θ after the sample is drawn. Further discussion on these distributions follows an illustrative example.

Example 11.1.1. Consider the model

$$\begin{aligned} X_i|\theta &\sim \text{iid Poisson}(\theta) \\ \Theta &\sim \Gamma(\alpha, \beta), \alpha \text{ and } \beta \text{ are known.} \end{aligned}$$

Hence the random sample is drawn from a Poisson distribution with mean θ and the prior distribution is a $\Gamma(\alpha, \beta)$ distribution. Let $\mathbf{X}' = (X_1, X_2, \dots, X_n)$. Thus, in this case, the joint conditional pdf of \mathbf{X} , given $\Theta = \theta$, (11.1.2), is

$$L(\mathbf{x}|\theta) = \frac{\theta^{x_1} e^{-\theta}}{x_1!} \cdots \frac{\theta^{x_n} e^{-\theta}}{x_n!}, \quad x_i = 0, 1, 2, \dots, i = 1, 2, \dots, n,$$

and the prior pdf is

$$h(\theta) = \frac{\theta^{\alpha-1} e^{-\theta/\beta}}{\Gamma(\alpha)\beta^\alpha}, \quad 0 < \theta < \infty.$$

Hence the joint mixed continuous-discrete pdf is given by

$$g(\mathbf{x}, \theta) = L(\mathbf{x}|\theta)h(\theta) = \left[\frac{\theta^{x_1} e^{-\theta}}{x_1!} \cdots \frac{\theta^{x_n} e^{-\theta}}{x_n!} \right] \left[\frac{\theta^{\alpha-1} e^{-\theta/\beta}}{\Gamma(\alpha)\beta^\alpha} \right],$$

provided that $x_i = 0, 1, 2, 3, \dots, i = 1, 2, \dots, n$, and $0 < \theta < \infty$, and is equal to zero elsewhere. Then the marginal distribution of the sample, (11.1.4), is

$$g_1(\mathbf{x}) = \int_0^\infty \frac{\theta^{\sum x_i + \alpha - 1} e^{-(n+1/\beta)\theta}}{x_1! \cdots x_n! \Gamma(\alpha)\beta^\alpha} d\theta = \frac{\Gamma\left(\sum_1^n x_i + \alpha\right)}{x_1! \cdots x_n! \Gamma(\alpha)\beta^\alpha (n+1/\beta)^{\sum x_i + \alpha}}. \quad (11.1.6)$$

Finally, the posterior pdf of Θ , given $\mathbf{X} = \mathbf{x}$, (11.1.5), is

$$k(\theta|\mathbf{x}) = \frac{L(\mathbf{x}|\theta)h(\theta)}{g_1(\mathbf{x})} = \frac{\theta^{\sum x_i + \alpha - 1} e^{-\theta/[\beta/(n\beta+1)]}}{\Gamma\left(\sum x_i + \alpha\right) [\beta/(n\beta+1)]^{\sum x_i + \alpha}}, \quad (11.1.7)$$

provided that $0 < \theta < \infty$, and is equal to zero elsewhere. This conditional pdf is of the gamma type, with parameters $\alpha^* = \sum_{i=1}^n x_i + \alpha$ and $\beta^* = \beta/(n\beta+1)$. Notice that the posterior pdf reflects both prior information (α, β) and sample information $(\sum_{i=1}^n x_i)$. ■

In Example 11.1.1, notice that it is not really necessary to determine the marginal pdf $g_1(\mathbf{x})$ to find the posterior pdf $k(\theta|\mathbf{x})$. If we divide $L(\mathbf{x}|\theta)h(\theta)$ by $g_1(\mathbf{x})$, we must get the product of a factor that depends upon \mathbf{x} but does *not* depend upon θ , say $c(\mathbf{x})$, and

$$\theta^{\sum x_i + \alpha - 1} e^{-\theta/[\beta/(n\beta+1)]}.$$

That is,

$$k(\theta|\mathbf{x}) = c(\mathbf{x}) \theta^{\sum x_i + \alpha - 1} e^{-\theta/[\beta/(n\beta+1)]},$$

provided that $0 < \theta < \infty$ and $x_i = 0, 1, 2, \dots$, $i = 1, 2, \dots, n$. However, $c(\mathbf{x})$ must be that “constant” needed to make $k(\theta|\mathbf{x})$ a pdf, namely,

$$c(\mathbf{x}) = \frac{1}{\Gamma\left(\sum x_i + \alpha\right) [\beta/(n\beta + 1)]^{\sum x_i + \alpha}}.$$

Accordingly, we frequently write that $k(\theta|\mathbf{x})$ is proportional to $L(\mathbf{x}|\theta)h(\theta)$; that is, the posterior pdf can be written as

$$k(\theta|\mathbf{x}) \propto L(\mathbf{x}|\theta)h(\theta). \quad (11.1.8)$$

Note that in the right-hand member of this expression, all factors involving constants and \mathbf{x} alone (not θ) can be dropped. For illustration, in solving the problem presented in Example 11.1.1, we simply write

$$k(\theta|\mathbf{x}) \propto \theta^{\sum x_i} e^{-n\theta} \theta^{\alpha-1} e^{-\theta/\beta}$$

or, equivalently,

$$k(\theta|\mathbf{x}) \propto \theta^{\sum x_i + \alpha - 1} e^{-\theta/[\beta/(n\beta + 1)]},$$

$0 < \theta < \infty$, and is equal to zero elsewhere. Clearly, $k(\theta|\mathbf{x})$ must be a gamma pdf with parameters $\alpha^* = \sum x_i + \alpha$ and $\beta^* = \beta/(n\beta + 1)$.

There is another observation that can be made at this point. Suppose that there exists a sufficient statistic $Y = u(\mathbf{X})$ for the parameter so that

$$L(\mathbf{x}|\theta) = g[u(\mathbf{x})|\theta]H(\mathbf{x}),$$

where now $g(y|\theta)$ is the pdf of Y , given $\Theta = \theta$. Then we note that

$$k(\theta|\mathbf{x}) \propto g[u(\mathbf{x})|\theta]h(\theta)$$

because the factor $H(\mathbf{x})$ that does not depend upon θ can be dropped. Thus, if a sufficient statistic Y for the parameter exists, we can begin with the pdf of Y if we wish and write

$$k(\theta|y) \propto g(y|\theta)h(\theta), \quad (11.1.9)$$

where now $k(\theta|y)$ is the conditional pdf of Θ given the sufficient statistic $Y = y$. In the case of a sufficient statistic Y , we also use $g_1(y)$ to denote the marginal pdf of Y ; that is, in the continuous case,

$$g_1(y) = \int_{-\infty}^{\infty} g(y|\theta)h(\theta) d\theta.$$

11.1.2 Bayesian Point Estimation

Suppose we want a point estimator of θ . From the Bayesian viewpoint, this really amounts to selecting a decision function δ , so that $\delta(\mathbf{x})$ is a predicted value of θ (an experimental value of the random variable Θ) when both the computed value \mathbf{x} and the conditional pdf $k(\theta|\mathbf{x})$ are known. Now, in general, how would we predict

an experimental value of any random variable, say W , if we want our prediction to be “reasonably close” to the value to be observed? Many statisticians would predict the mean, $E(W)$, of the distribution of W ; others would predict a median (perhaps unique) of the distribution of W ; and some would have other predictions. However, it seems desirable that the choice of the decision function should depend upon a loss function $\mathcal{L}[\theta, \delta(\mathbf{x})]$. One way in which this dependence upon the loss function can be reflected is to select the decision function δ in such a way that the conditional expectation of the loss is a minimum. A **Bayes estimate** is a decision function δ that minimizes

$$E\{\mathcal{L}[\Theta, \delta(\mathbf{x})] | \mathbf{X} = \mathbf{x}\} = \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(\mathbf{x})] k(\theta | \mathbf{x}) d\theta$$

if Θ is a random variable of the continuous type. That is,

$$\delta(\mathbf{x}) = \operatorname{Argmin}_{\delta(\mathbf{x})} \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(\mathbf{x})] k(\theta | \mathbf{x}) d\theta. \quad (11.1.10)$$

The associated random variable $\delta(\mathbf{X})$ is called a **Bayes estimator** of θ . The usual modification of the right-hand member of this equation is made for random variables of the discrete type. If the loss function is given by $\mathcal{L}[\theta, \delta(\mathbf{x})] = [\theta - \delta(\mathbf{x})]^2$, then the Bayes estimate is $\delta(\mathbf{x}) = E(\Theta | \mathbf{x})$, the mean of the conditional distribution of Θ , given $\mathbf{X} = \mathbf{x}$. This follows from the fact that $E[(W - b)^2]$, if it exists, is a minimum when $b = E(W)$. If the loss function is given by $\mathcal{L}[\theta, \delta(\mathbf{x})] = |\theta - \delta(\mathbf{x})|$, then a median of the conditional distribution of Θ , given $\mathbf{X} = \mathbf{x}$, is the Bayes solution. This follows from the fact that $E(|W - b|)$, if it exists, is a minimum when b is equal to any median of the distribution of W .

It is easy to generalize this to estimate a specified function of θ , say, $l(\theta)$. For the loss function $\mathcal{L}[\theta, \delta(\mathbf{x})]$, a **Bayes estimate** of $l(\theta)$ is a decision function δ that minimizes

$$E\{\mathcal{L}[l(\Theta), \delta(\mathbf{x})] | \mathbf{X} = \mathbf{x}\} = \int_{-\infty}^{\infty} \mathcal{L}[l(\theta), \delta(\mathbf{x})] k(\theta | \mathbf{x}) d\theta.$$

The random variable $\delta(\mathbf{X})$ is called a **Bayes estimator** of $l(\theta)$.

The conditional expectation of the loss, given $\mathbf{X} = \mathbf{x}$, defines a random variable that is a function of the sample \mathbf{X} . The expected value of that function of \mathbf{X} , in the notation of this section, is given by

$$\int_{-\infty}^{\infty} \left\{ \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(\mathbf{x})] k(\theta | \mathbf{x}) d\theta \right\} g_1(\mathbf{x}) d\mathbf{x} = \int_{-\infty}^{\infty} \left\{ \int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(\mathbf{x})] L(\mathbf{x} | \theta) d\mathbf{x} \right\} h(\theta) d\theta,$$

in the continuous case. The integral within the braces in the latter expression is, for every given $\theta \in \Theta$, the **risk function** $R(\theta, \delta)$; accordingly, the latter expression is the mean value of the risk, or the expected risk. Because a Bayes estimate $\delta(\mathbf{x})$ minimizes

$$\int_{-\infty}^{\infty} \mathcal{L}[\theta, \delta(\mathbf{x})] k(\theta | \mathbf{x}) d\theta$$

for every \mathbf{x} for which $g(\mathbf{x}) > 0$, it is evident that a Bayes estimate $\delta(\mathbf{x})$ minimizes this mean value of the risk. We now give two illustrative examples.

Example 11.1.2. Consider the model

$$\begin{aligned} X_i|\theta &\sim \text{iid binomial, } b(1, \theta) \\ \Theta &\sim \text{beta}(\alpha, \beta), \alpha \text{ and } \beta \text{ are known;} \end{aligned}$$

that is, the prior pdf is

$$h(\theta) = \begin{cases} \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)}\theta^{\alpha-1}(1-\theta)^{\beta-1} & 0 < \theta < 1 \\ 0 & \text{elsewhere.} \end{cases}$$

where α and β are assigned positive constants. We seek a decision function δ that is a Bayes solution. The sufficient statistic is $Y = \sum_1^n X_i$, which has a $b(n, \theta)$ distribution. Thus the conditional pdf of Y given $\Theta = \theta$ is

$$g(y|\theta) = \begin{cases} \binom{n}{y}\theta^y(1-\theta)^{n-y} & y = 0, 1, \dots, n \\ 0 & \text{elsewhere.} \end{cases}$$

Thus, by (11.1.9), the conditional pdf of Θ , given $Y = y$ at points of positive probability density, is

$$k(\theta|y) \propto \theta^y(1-\theta)^{n-y}\theta^{\alpha-1}(1-\theta)^{\beta-1}, \quad 0 < \theta < 1.$$

That is,

$$k(\theta|y) = \frac{\Gamma(n + \alpha + \beta)}{\Gamma(\alpha + y)\Gamma(n + \beta - y)}\theta^{\alpha+y-1}(1-\theta)^{\beta+n-y-1}, \quad 0 < \theta < 1,$$

and $y = 0, 1, \dots, n$. Hence the posterior pdf is a beta density function with parameters $(\alpha + y, \beta + n - y)$. We take the squared-error loss, i.e., $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$, as the loss function. Then, the Bayesian point estimate of θ is the mean of this beta pdf, which is

$$\delta(y) = \frac{\alpha + y}{\alpha + \beta + n}.$$

It is very instructive to note that this Bayes estimator can be written as

$$\delta(y) = \left(\frac{n}{\alpha + \beta + n}\right)\frac{y}{n} + \left(\frac{\alpha + \beta}{\alpha + \beta + n}\right)\frac{\alpha}{\alpha + \beta},$$

which is a weighted average of the maximum likelihood estimate y/n of θ and the mean $\alpha/(\alpha + \beta)$ of the prior pdf of the parameter. Moreover, the respective weights are $n/(\alpha + \beta + n)$ and $(\alpha + \beta)/(\alpha + \beta + n)$. Note that for large n , the Bayes estimate is close to the maximum likelihood estimate of θ and that, furthermore, $\delta(Y)$ is a consistent estimator of θ . Thus we see that α and β should be selected so that not only is $\alpha/(\alpha + \beta)$ the desired prior mean, but the sum $\alpha + \beta$ indicates the worth of the prior opinion relative to a sample of size n . That is, if we want our prior opinion to have as much weight as a sample size of 20, we would take $\alpha + \beta = 20$. So if our prior mean is $\frac{3}{4}$, we have that α and β are selected so that $\alpha = 15$ and $\beta = 5$. ■

Example 11.1.3. For this example, we have the normal model,

$$\begin{aligned} X_i | \theta &\sim \text{iid } N(\theta, \sigma^2), \text{ where } \sigma^2 \text{ is known} \\ \Theta &\sim N(\theta_0, \sigma_0^2), \text{ where } \theta_0 \text{ and } \sigma_0^2 \text{ are known.} \end{aligned}$$

Then $Y = \bar{X}$ is a sufficient statistic. Hence an equivalent formulation of the model is

$$\begin{aligned} Y | \theta &\sim N(\theta, \sigma^2/n), \text{ where } \sigma^2 \text{ is known} \\ \Theta &\sim N(\theta_0, \sigma_0^2), \text{ where } \theta_0 \text{ and } \sigma_0^2 \text{ are known.} \end{aligned}$$

Then for the posterior pdf, we have

$$k(\theta|y) \propto \frac{1}{\sqrt{2\pi}\sigma/\sqrt{n}} \frac{1}{\sqrt{2\pi}\sigma_0} \exp \left[-\frac{(y-\theta)^2}{2(\sigma^2/n)} - \frac{(\theta-\theta_0)^2}{2\sigma_0^2} \right].$$

If we eliminate all constant factors (including factors involving only y), we have

$$k(\theta|y) \propto \exp \left[-\frac{[\sigma_0^2 + (\sigma^2/n)]\theta^2 - 2[y\sigma_0^2 + \theta_0(\sigma^2/n)]\theta}{2(\sigma^2/n)\sigma_0^2} \right].$$

This can be simplified by completing the square to read (after eliminating factors not involving θ)

$$k(\theta|y) \propto \exp \left[-\frac{\left(\theta - \frac{y\sigma_0^2 + \theta_0(\sigma^2/n)}{\sigma_0^2 + (\sigma^2/n)} \right)^2}{\frac{2(\sigma^2/n)\sigma_0^2}{[\sigma_0^2 + (\sigma^2/n)]}} \right].$$

That is, the posterior pdf of the parameter is obviously normal with mean

$$\frac{y\sigma_0^2 + \theta_0(\sigma^2/n)}{\sigma_0^2 + (\sigma^2/n)} = \left(\frac{\sigma_0^2}{\sigma_0^2 + (\sigma^2/n)} \right) y + \left(\frac{\sigma^2/n}{\sigma_0^2 + (\sigma^2/n)} \right) \theta_0 \quad (11.1.11)$$

and variance $(\sigma^2/n)\sigma_0^2/[\sigma_0^2 + (\sigma^2/n)]$. If the squared-error loss function is used, this posterior mean is the Bayes estimator. Again, note that it is a weighted average of the maximum likelihood estimate $y = \bar{x}$ and the prior mean θ_0 . As in the last example, for large n , the Bayes estimator is close to the maximum likelihood estimator and $\delta(Y)$ is a consistent estimator of θ . Thus the Bayesian procedures permit the decision maker to enter his or her prior opinions into the solution in a very formal way such that the influences of these prior notions are less and less as n increases. ■

In Bayesian statistics, all the information is contained in the posterior pdf $k(\theta|y)$. In Examples 11.1.2 and 11.1.3, we found Bayesian point estimates using the squared-error loss function. It should be noted that if $\mathcal{L}[\delta(y), \theta] = |\delta(y) - \theta|$, the absolute value of the error, then the Bayes solution would be the median of the posterior distribution of the parameter, which is given by $k(\theta|y)$. Hence the Bayes estimator changes, as it should, with different loss functions.

11.1.3 Bayesian Interval Estimation

If an interval estimate of θ is desired, we can find two functions $u(\mathbf{x})$ and $v(\mathbf{x})$ so that the conditional probability

$$P[u(\mathbf{x}) < \Theta < v(\mathbf{x}) | \mathbf{X} = \mathbf{x}] = \int_{u(\mathbf{x})}^{v(\mathbf{x})} k(\theta | \mathbf{x}) d\theta$$

is large, for example, 0.95. Then the interval $u(\mathbf{x})$ to $v(\mathbf{x})$ is an interval estimate of θ in the sense that the conditional probability of Θ belonging to that interval is equal to 0.95. These intervals are often called **credible or probability intervals**, so as not to confuse them with confidence intervals.

Example 11.1.4. Consider Example 11.1.3, where X_1, X_2, \dots, X_n is a random sample from a $N(\theta, \sigma^2)$ distribution, where σ^2 is known, and the prior distribution is a normal $N(\theta_0, \sigma_0^2)$ distribution. The statistic $Y = \bar{X}$ is sufficient. Recall that the posterior pdf of Θ given $Y = y$ was normal with mean and variance given near expression (11.1.11). Hence a credible interval is found by taking the mean of the posterior distribution and adding and subtracting 1.96 of its standard deviation; that is, the interval

$$\frac{y\sigma_0^2 + \theta_0(\sigma^2/n)}{\sigma_0^2 + (\sigma^2/n)} \pm 1.96 \sqrt{\frac{(\sigma^2/n)\sigma_0^2}{\sigma_0^2 + (\sigma^2/n)}}$$

forms a credible interval of probability 0.95 for θ . ■

Example 11.1.5. Recall Example 11.1.1, where $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ is a random sample from a Poisson distribution with mean θ and a $\Gamma(\alpha, \beta)$ prior, with α and β known, is considered. As given by expression (11.1.7), the posterior pdf is a $\Gamma(y + \alpha, \beta/(n\beta + 1))$ pdf, where $y = \sum_{i=1}^n x_i$. Hence, if we use the squared-error loss function, the Bayes point estimate of θ is the mean of the posterior

$$\delta(y) = \frac{\beta(y + \alpha)}{n\beta + 1} = \frac{n\beta}{n\beta + 1} \frac{y}{n} + \frac{\alpha\beta}{n\beta + 1}.$$

As with the other Bayes estimates we have discussed in this section, for large n this estimate is close to the maximum likelihood estimate and the statistic $\delta(Y)$ is a consistent estimate of θ . To obtain a credible interval, note that the posterior distribution of $\frac{2(n\beta+1)}{\beta}\Theta$ is $\chi^2(2(\sum_{i=1}^n x_i + \alpha))$. Based on this, the following interval is a $(1 - \alpha)100\%$ credible interval for θ :

$$\left(\frac{\beta}{2(n\beta + 1)} \chi_{1-(\alpha/2)}^2 \left[2 \left(\sum_{i=1}^n x_i + \alpha \right) \right], \frac{\beta}{2(n\beta + 1)} \chi_{\alpha/2}^2 \left[2 \left(\sum_{i=1}^n x_i + \alpha \right) \right] \right), \quad (11.1.12)$$

where $\chi_{1-(\alpha/2)}^2(2(\sum_{i=1}^n x_i + \alpha))$ and $\chi_{\alpha/2}^2(2(\sum_{i=1}^n x_i + \alpha))$ are the lower and upper χ^2 quantiles for a χ^2 distribution with $2(\sum_{i=1}^n x_i + \alpha)$ degrees of freedom. ■

11.1.4 Bayesian Testing Procedures

As above, let X be a random variable with pdf (pmf) $f(x|\theta)$, $\theta \in \Omega$. Suppose we are interested in testing the hypotheses

$$H_0 : \theta \in \omega_0 \text{ versus } H_1 : \theta \in \omega_1,$$

where $\omega_0 \cup \omega_1 = \Omega$ and $\omega_0 \cap \omega_1 = \emptyset$. A simple Bayesian procedure to test these hypotheses proceeds as follows. Let $h(\theta)$ denote the prior distribution of the prior random variable Θ ; let $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ denote a random sample on X ; and denote the posterior pdf or pmf by $k(\theta|\mathbf{x})$. We use the posterior distribution to compute the following conditional probabilities:

$$P(\Theta \in \omega_0 | \mathbf{x}) \text{ and } P(\Theta \in \omega_1 | \mathbf{x}).$$

In the Bayesian framework, these conditional probabilities represent the truth of H_0 and H_1 , respectively. A simple rule is to

$$\text{Accept } H_0 \text{ if } P(\Theta \in \omega_0 | \mathbf{x}) \geq P(\Theta \in \omega_1 | \mathbf{x});$$

otherwise, accept H_1 ; that is, accept the hypothesis that has the greater conditional probability. Note that the condition $\omega_0 \cap \omega_1 = \emptyset$ is required, but $\omega_0 \cup \omega_1 = \Omega$ is not necessary. More than two hypotheses may be tested at the same time, in which case a simple rule would be to accept the hypothesis with the greater conditional probability. We finish this subsection with a numerical example.

Example 11.1.6. Referring again to Example 11.1.1, where $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ is a random sample from a Poisson distribution with mean θ , suppose we are interested in testing

$$H_0 : \theta \leq 10 \text{ versus } H_1 : \theta > 10. \quad (11.1.13)$$

Suppose we think θ is about 12, but we are not quite sure. Hence we choose the $\Gamma(10, 1.2)$ pdf as our prior, which is shown in the left panel of Figure 11.1.1. The mean of the prior is 12, but as the plot shows, there is some variability (the variance of the prior distribution is 14.4). The data for the problem are

$$\begin{array}{cccccccccccc} 11 & 7 & 11 & 6 & 5 & 9 & 14 & 10 & 9 & 5 \\ 8 & 10 & 8 & 10 & 12 & 9 & 3 & 12 & 14 & 4 \end{array}$$

(these are the values of a random sample of size $n = 20$ taken from a Poisson distribution with mean 8; of course, in practice we would not know the mean is 8). The value of the sufficient statistic is $y = \sum_{i=1}^{20} x_i = 177$. Hence, from Example 11.1.1, the posterior distribution is a $\Gamma(177 + 10, 1.2/[20(1.2) + 1]) = \Gamma(187, 0.048)$ distribution, which is shown in the right panel of Figure 11.1.1. Note that the data have moved the mean to the left of 12 to $187(0.048) = 8.976$, which is the Bayes estimate (under squared-error loss) of θ . Using R, we compute the posterior probability of H_0 as

$$P[\Theta \leq 10 | y = 177] = P[\Gamma(187, 0.048) \leq 10] = \text{pgamma}(10, 187, 1/0.048) = 0.9368.$$

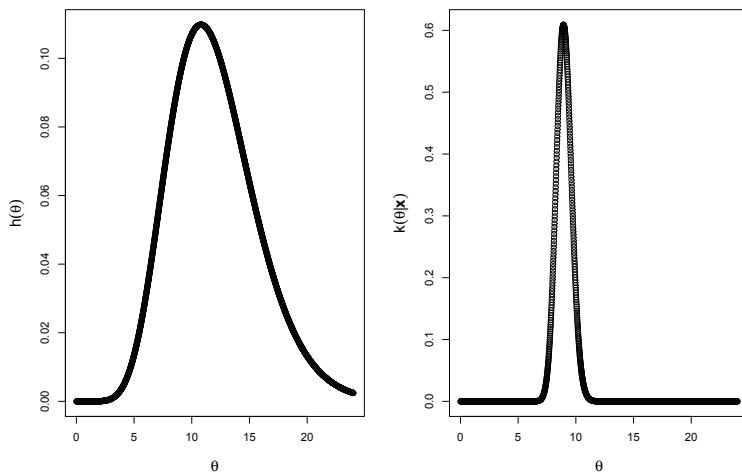

Figure 11.1.1: Prior (left panel) and posterior (right panel) pdfs of Example 11.1.6

Thus $P[\Theta > 10|y = 177] = 1 - 0.9368 = 0.0632$; consequently, our rule would accept H_0 .

The 95% credible interval, (11.1.12), is $(7.77, 10.31)$, which also contains 10; see Exercise 11.1.7 for details. ■

11.1.5 Bayesian Sequential Procedures

Finally, we should observe what a Bayesian would do if additional data were collected beyond x_1, x_2, \dots, x_n . In such a situation, the posterior distribution found with the observations x_1, x_2, \dots, x_n becomes the new prior distribution, additional observations give a new posterior distribution, and inferences would be made from that second posterior. Of course, this can continue with even more observations. That is, the second posterior becomes the new prior, and the next set of observations yields the next posterior from which the inferences can be made. Clearly, this gives Bayesians an excellent way of handling sequential analysis. They can continue taking data, always updating the previous posterior, which has become a new prior distribution. Everything a Bayesian needs for inferences is in that final posterior distribution obtained by this sequential procedure.

EXERCISES

- 11.1.1.** Let Y have a binomial distribution in which $n = 20$ and $p = \theta$. The prior probabilities on θ are $P(\theta = 0.3) = 2/3$ and $P(\theta = 0.5) = 1/3$. If $y = 9$, what are the posterior probabilities for $\theta = 0.3$ and $\theta = 0.5$?

11.1.2. Let X_1, X_2, \dots, X_n be a random sample from a distribution that is $b(1, \theta)$. Let the prior of Θ be a beta one with parameters α and β . Show that the posterior pdf $k(\theta|x_1, x_2, \dots, x_n)$ is exactly the same as $k(\theta|y)$ given in Example 11.1.2.

11.1.3. Let X_1, X_2, \dots, X_n denote a random sample from a distribution that is $N(\theta, \sigma^2)$, where $-\infty < \theta < \infty$ and σ^2 is a given positive number. Let $Y = \bar{X}$ denote the mean of the random sample. Take the loss function to be $\mathcal{L}[\theta, \delta(y)] = |\theta - \delta(y)|$. If θ is an observed value of the random variable Θ that is $N(\mu, \tau^2)$, where $\tau^2 > 0$ and μ are known numbers, find the Bayes solution $\delta(y)$ for a point estimate θ .

11.1.4. Let X_1, X_2, \dots, X_n denote a random sample from a Poisson distribution with mean θ , $0 < \theta < \infty$. Let $Y = \sum_i^n X_i$. Use the loss function $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y)]^2$. Let θ be an observed value of the random variable Θ . If Θ has the prior pdf $h(\theta) = \theta^{\alpha-1} e^{-\theta/\beta} / \Gamma(\alpha)\beta^\alpha$, for $0 < \theta < \infty$, zero elsewhere, where $\alpha > 0$, $\beta > 0$ are known numbers, find the Bayes solution $\delta(y)$ for a point estimate for θ .

11.1.5. Let Y_n be the n th order statistic of a random sample of size n from a distribution with pdf $f(x|\theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere. Take the loss function to be $\mathcal{L}[\theta, \delta(y)] = [\theta - \delta(y_n)]^2$. Let θ be an observed value of the random variable Θ , which has the prior pdf $h(\theta) = \beta\alpha^\beta/\theta^{\beta+1}$, $\alpha < \theta < \infty$, zero elsewhere, with $\alpha > 0$, $\beta > 0$. Find the Bayes solution $\delta(y_n)$ for a point estimate of θ .

11.1.6. Let Y_1 and Y_2 be statistics that have a trinomial distribution with parameters n , θ_1 , and θ_2 . Here θ_1 and θ_2 are observed values of the random variables Θ_1 and Θ_2 , which have a Dirichlet distribution with known parameters α_1 , α_2 , and α_3 ; see expression (3.3.10). Show that the conditional distribution of Θ_1 and Θ_2 is Dirichlet and determine the conditional means $E(\Theta_1|y_1, y_2)$ and $E(\Theta_2|y_1, y_2)$.

11.1.7. For Example 11.1.6, obtain the 95% credible interval for θ . Next obtain the value of the mle for θ and the 95% confidence interval for θ discussed in Chapter 6.

11.1.8. In Example 11.1.2, let $n = 30$, $\alpha = 10$, and $\beta = 5$, so that $\delta(y) = (10+y)/45$ is the Bayes estimate of θ .

- (a) If Y has a binomial distribution $b(30, \theta)$, compute the risk $E\{[\theta - \delta(Y)]^2\}$.
- (b) Find values of θ for which the risk of part (a) is less than $\theta(1-\theta)/30$, the risk associated with the maximum likelihood estimator Y/n of θ .

11.1.9. Let Y_4 be the largest order statistic of a sample of size $n = 4$ from a distribution with uniform pdf $f(x;\theta) = 1/\theta$, $0 < x < \theta$, zero elsewhere. If the prior pdf of the parameter $g(\theta) = 2/\theta^3$, $1 < \theta < \infty$, zero elsewhere, find the Bayesian estimator $\delta(Y_4)$ of θ , based upon the sufficient statistic Y_4 , using the loss function $|\delta(y_4) - \theta|$.

11.1.10. Refer to Example 11.2.3; suppose we select $\sigma_0^2 = d\sigma^2$, where σ^2 was known in that example. What value do we assign to d so that the variance of posterior is two-thirds the variance of $Y = \bar{X}$, namely, σ^2/n ?

11.2 More Bayesian Terminology and Ideas

Suppose $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ represents a random sample with likelihood $L(\mathbf{x}|\theta)$ and we assume a prior pdf $h(\theta)$. The joint marginal pdf of \mathbf{X} is given by

$$g_1(\mathbf{x}) = \int_{-\infty}^{\infty} L(\mathbf{x}|\theta)h(\theta)d\theta.$$

This is often called the pdf of the **predictive distribution** of \mathbf{X} because it provides the best description of the probabilities about \mathbf{X} given the likelihood and the prior. An illustration of this is provided in expression (11.1.6) of Example 11.1.1. Again note that this predictive distribution is highly dependent on the probability models for X and Θ .

In this section, we consider two classes of prior distributions. The first class is the class of conjugate priors defined by:

Definition 11.2.1. A class of prior pdfs for the family of distributions with pdfs $f(x|\theta)$, $\theta \in \Omega$, is said to define a **conjugate family of distributions** if the posterior pdf of the parameter is in the same family of distributions as the prior.

As an illustration, consider Example 11.1.5, where the pmf of X_i given θ was Poisson with mean θ . In this example, we selected a gamma prior and the resulting posterior distribution was of the gamma family also. Hence the gamma pdf forms a conjugate class of priors for this Poisson model. This was true also for Example 11.1.2 where the conjugate family was beta and the model was a binomial, and for Example 11.1.3, where both the model and the prior were normal.

To motivate our second class of priors, consider the binomial model, $b(1,\theta)$, presented in Example 11.1.2. Thomas Bayes (1763) took as a prior the beta distribution with $\alpha = \beta = 1$, namely $h(\theta) = 1, 0 < \theta < 1$, zero elsewhere, because he argued that he did not have much prior knowledge about θ . However, we note that this leads to the estimate of

$$\left(\frac{n}{n+2}\right)\left(\frac{y}{n}\right) + \left(\frac{2}{n+2}\right)\left(\frac{1}{2}\right).$$

We often call this a **shrinkage** estimate because the estimate y/n is pulled a little toward the prior mean of 1/2, although Bayes tried to avoid having the prior influence the inference.

Haldane (1948) did note, however, that if a prior beta pdf exists with $\alpha = \beta = 0$, then the shrinkage estimate would reduce to the mle y/n . Of course, a beta pdf with $\alpha = \beta = 0$ is not a pdf at all, for it would be such that

$$h(\theta) \propto \frac{1}{\theta(1-\theta)}, \quad 0 < \theta < 1,$$

zero elsewhere, and

$$\int_0^1 \frac{c}{\theta(1-\theta)} d\theta$$

does not exist. However, such priors are used if, when combined with the likelihood, we obtain a posterior pdf which is a proper pdf. By **proper**, we mean that it integrates to a positive constant. In this example, we obtain the posterior pdf of

$$f(\theta|y) \propto \theta^{y-1} (1-\theta)^{n-y-1},$$

which is proper provided $y > 0$ and $n - y > 0$. Of course, the posterior mean is y/n .

Definition 11.2.2. Let $\mathbf{X}' = (X_1, X_2, \dots, X_n)$ be a random sample from the distribution with pdf $f(x|\theta)$. A prior $h(\theta) \geq 0$ for this family is said to be **improper** if it is not a pdf, but the function $k(\theta|\mathbf{x}) \propto L(\mathbf{x}|\theta)h(\theta)$ can be made proper.

A **noninformative prior** is a prior that treats all values of θ the same, that is, uniformly. Continuous noninformative priors are often improper. As an example, suppose we have a normal distribution $N(\theta_1, \theta_2)$ in which both θ_1 and $\theta_2 > 0$ are unknown. A noninformative prior for θ_1 is $h_1(\theta_1) = 1$, $-\infty < \theta_1 < \infty$. Clearly, this is not a pdf. An improper prior for θ_2 is $h_2(\theta_2) = c_2/\theta_2$, $0 < \theta_2 < \infty$, zero elsewhere. Note that $\log \theta_2$ is uniformly distributed between $-\infty < \log \theta_2 < \infty$. Hence, in this way, it is a noninformative prior. In addition, assume the parameters are independent. Then the joint prior, which is improper, is

$$h_1(\theta_1)h_2(\theta_2) \propto 1/\theta_2, \quad -\infty < \theta_1 < \infty, 0 < \theta_2 < \infty. \quad (11.2.1)$$

Using this prior, we present the Bayes solution for θ_1 in the next example.

Example 11.2.1. Let X_1, X_2, \dots, X_n be a random sample from a $N(\theta_1, \theta_2)$ distribution. Recall that \bar{X} and $S^2 = (n-1)^{-1} \sum_{i=1}^n (X_i - \bar{X})^2$ are sufficient statistics. Suppose we use the improper prior given by (11.2.1). Then the posterior distribution is given by

$$\begin{aligned} k_{12}(\theta_1, \theta_2 | \bar{x}, s^2) &\propto \left(\frac{1}{\theta_2}\right) \left(\frac{1}{\sqrt{2\pi\theta_2}}\right)^n \exp\left[-\frac{1}{2}\{(n-1)s^2 + n(\bar{x} - \theta_1)^2\}/\theta_2\right] \\ &\propto \left(\frac{1}{\theta_2}\right)^{\frac{n}{2}+1} \exp\left[-\frac{1}{2}\{(n-1)s^2 + n(\bar{x} - \theta_1)^2\}/\theta_2\right]. \end{aligned}$$

To get the conditional pdf of θ_1 , given \bar{x} and s^2 , we integrate out θ_2

$$k_1(\theta_1 | \bar{x}, s^2) = \int_0^\infty k_{12}(\theta_1, \theta_2 | \bar{x}, s^2) d\theta_2.$$

To carry this out, let us change variables $z = 1/\theta_2$ and $\theta_2 = 1/z$, with Jacobian $-1/z^2$. Thus

$$k_1(\theta_1 | \bar{x}, s^2) \propto \int_0^\infty \frac{z^{\frac{n}{2}+1}}{z^2} \exp\left[-\left\{\frac{(n-1)s^2 + n(\bar{x} - \theta_1)^2}{2}\right\} z\right] dz.$$

Referring to a gamma distribution with $\alpha = n/2$ and $\beta = 2/\{(n-1)s^2 + n(\bar{x} - \theta_1)^2\}$, this result is proportional to

$$k_1(\theta_1 | \bar{x}, s^2) \propto \{(n-1)s^2 + n(\bar{x} - \theta_1)^2\}^{-n/2}.$$

Let us change variables to get more familiar results; namely, let

$$t = \frac{\theta_1 - \bar{x}}{s/\sqrt{n}} \text{ and } \theta_1 = \bar{x} + ts/\sqrt{n},$$

with Jacobian s/\sqrt{n} . This conditional pdf of t , given \bar{x} and s^2 , is then

$$\begin{aligned} k(t|\bar{x}, s^2) &\propto \{(n-1)s^2 + (st)^2\}^{-n/2} \\ &\propto \frac{1}{[1+t^2/(n-1)]^{[(n-1)+1]/2}}. \end{aligned}$$

That is, the conditional pdf of $t = (\theta_1 - \bar{x})/(s/n)$, given \bar{x} and s^2 , is a Student t with $n-1$ degrees of freedom. Since the mean of this pdf is 0 (assuming that $n > 2$), it follows that the Bayes estimator of θ_1 , under squared-error loss, is \bar{X} , which is also the mle.

Of course, from $k_1(\theta_1|\bar{x}, s^2)$ or $k(t|\bar{x}, s^2)$, we can find a credible interval for θ_1 . One way of doing this is to select the *highest density region* (HDR) of the pdf θ_1 or that of t . The former is symmetric and unimodal about θ_1 and the latter about zero, but the latter's critical values are tabulated; so we use the HDR of that t -distribution. Thus, if we want an interval having probability $1 - \alpha$, we take

$$-t_{\alpha/2} < \frac{\theta_1 - \bar{x}}{s/\sqrt{n}} < t_{\alpha/2}$$

or, equivalently,

$$\bar{x} - t_{\alpha/2}s/\sqrt{n} < \theta_1 < \bar{x} + t_{\alpha/2}s/\sqrt{n}.$$

This interval is the same as the confidence interval for θ_1 ; see Example 4.2.1. Hence, in this case, the improper prior (11.2.1) leads to the same inference as the traditional analysis. ■

Example 11.2.2. Usually in a Bayesian analysis, noninformative priors are not used if prior information exists. Let us consider the same situation as in Example 11.2.1, where the model was a $N(\theta_1, \theta_2)$ distribution. Suppose now we consider the precision $\theta_3 = 1/\theta_2$ instead of variance θ_2 . The likelihood becomes

$$\left(\frac{\theta_3}{2\pi}\right)^{n/2} \exp\left[-\frac{1}{2}\{(n-1)s^2 + n(\bar{x} - \theta_1)^2\}\theta_3\right],$$

so that it is clear that a conjugate prior for θ_3 is $\Gamma(\alpha, \beta)$. Further, given θ_3 , a reasonable prior on θ_1 is $N(\theta_0, \frac{1}{n_0\theta_3})$, where n_0 is selected in some way to reflect how many observations the prior is worth. Thus the joint prior of θ_1 and θ_3 is

$$h(\theta_1, \theta_3) \propto \theta_3^{\alpha-1} e^{-\theta_3/\beta} (n_0\theta_3)^{1/2} e^{-(\theta_1 - \theta_0)^2\theta_3 n_0/2}.$$

If this is multiplied by the likelihood function, we obtain the posterior joint pdf of θ_1 and θ_3 , namely,

$$k(\theta_1, \theta_3 | \bar{x}, s^2) \propto \theta_3^{\alpha + \frac{n}{2} + \frac{1}{2} - 1} \exp\left[-\frac{1}{2}Q(\theta_1)\theta_3\right],$$

where

$$\begin{aligned} Q(\theta_1) &= \frac{2}{\beta} + n_0(\theta_1 - \theta_0)^2 + [(n-1)s^2 + n(\bar{x} - \theta_1)^2] \\ &= (n_0 + n) \left[\left(\theta_1 - \frac{n_0\theta_0 + n\bar{x}}{n_0 + n} \right)^2 \right] + D, \end{aligned}$$

with

$$D = \frac{2}{\beta} + (n-1)s^2 + (n_0^{-1} + n^{-1})^{-1}(\theta_0 - \bar{x})^2.$$

If we integrate out θ_3 , we obtain

$$\begin{aligned} k_1(\theta_1 | \bar{x}, s^2) &\propto \int_0^\infty k(\theta_1, \theta_3 | \bar{x}, s^2) d\theta_3 \\ &\propto \frac{1}{[Q(\theta_1)]^{[2\alpha+n+1]/2}}. \end{aligned}$$

To get this in a more familiar form, change variables by letting

$$t = \frac{\theta_1 - \frac{n_0\theta_0 + n\bar{x}}{n_0 + n}}{\sqrt{D/[(n_0 + n)(2\alpha + n)]}},$$

with Jacobian $\sqrt{D/[(n_0 + n)(2\alpha + n)]}$. Thus

$$k_2(t | \bar{x}, s^2) \propto \frac{1}{\left[1 + \frac{t^2}{2\alpha + n} \right]^{(2\alpha+n+1)/2}},$$

which is a Student t distribution with $2\alpha + n$ degrees of freedom. The Bayes estimate (under squared-error loss) in this case is

$$\frac{n_0\theta_0 + n\bar{x}}{n_0 + n}.$$

It is interesting to note that if we define “new” sample characteristics as

$$\begin{aligned} n_k &= n_0 + n \\ \bar{x}_k &= \frac{n_0\theta_0 + n\bar{x}}{n_0 + n} \\ s_k^2 &= \frac{D}{2\alpha + n}, \end{aligned}$$

then

$$t = \frac{\theta_1 - \bar{x}_k}{s_k / \sqrt{n_k}}$$

has a t -distribution with $2\alpha + n$ degrees of freedom. Of course, using these degrees of freedom, we can find $t_{\gamma/2}$ so that

$$\bar{x}_k \pm t_{\gamma/2} \frac{s_k}{\sqrt{n_k}}$$

is an HDR credible interval estimate for θ_1 with probability $1 - \gamma$. Naturally, it falls upon the Bayesian to assign appropriate values to α, β, n_0 , and θ_0 . Small values of α and n_0 with a large value of β would create a prior, so that this interval estimate would differ very little from the usual one. ■

Finally, it should be noted that when dealing with symmetric, unimodal posterior distributions, it was extremely easy to find the HDR interval estimate. If, however, that posterior distribution is not symmetric, it is more difficult and often the Bayesian would find the interval that has equal probabilities on each tail.

EXERCISES

11.2.1. Let X_1, X_2 be a random sample from a Cauchy distribution with pdf

$$f(x; \theta_1, \theta_2) = \left(\frac{1}{\pi} \right) \frac{\theta_2}{\theta_2^2 + (x - \theta_1)^2}, \quad -\infty < x < \infty,$$

where $-\infty < \theta_1 < \infty$, $0 < \theta_2$. Use the noninformative prior $h(\theta_1, \theta_2) \propto 1$.

- (a) Find the posterior pdf of θ_1, θ_2 , other than the constant of proportionality.
- (b) Evaluate this posterior pdf if $x_1 = 1, x_2 = 4$ for $\theta_1 = 1, 2, 3, 4$ and $\theta_2 = 0.5, 1.0, 1.5, 2.0$.
- (c) From the 16 values in part (b), where does the maximum of the posterior pdf seem to be?
- (d) Do you know a computer program that can find the point (θ_1, θ_2) of maximum?

11.2.2. Let X_1, X_2, \dots, X_{10} be a random sample of size $n = 10$ from a gamma distribution with $\alpha = 3$ and $\beta = 1/\theta$. Suppose we believe that θ has a gamma distribution with $\alpha = 10$ and $\beta = 2$.

- (a) Find the posterior distribution of θ .
- (b) If the observed $\bar{x} = 18.2$, what is the Bayes point estimate associated with square-error loss function?
- (c) What is the Bayes point estimate using the mode of the posterior distribution?
- (d) Comment on an HDR interval estimate for θ . Would it be easier to find one having equal tail probabilities?

Hint: Can the posterior distribution be related to a chi-square distribution?

11.2.3. Suppose for the situation of Example 11.2.2, θ_1 has the prior distribution $N(75, 1/(5\theta_3))$ and θ_3 has the prior distribution $\Gamma(\alpha = 4, \beta = 0.5)$. Suppose the observed sample of size $n = 50$ resulted in $\bar{x} = 77.02$ and $s^2 = 8.2$.

- (a) Find the Bayes point estimate of the mean θ_1 .
- (b) Determine an HDR interval estimate with $1 - \gamma = 0.90$.

11.2.4. Let $f(x|\theta)$, $\theta \in \Omega$, be a pdf with Fisher information, (6.2.4), $I(\theta)$. Consider the Bayes model

$$\begin{aligned} X|\theta &\sim f(x|\theta), \quad \theta \in \Omega \\ \Theta &\sim h(\theta) \propto \sqrt{I(\theta)}. \end{aligned} \quad (11.2.2)$$

- (a) Suppose we are interested in a parameter $\tau = u(\theta)$. Use the chain rule to prove that

$$\sqrt{I(\tau)} = \sqrt{I(\theta)} \left| \frac{\partial \theta}{\partial \tau} \right|. \quad (11.2.3)$$

- (b) Show that for the Bayes model (11.2.2), the prior pdf for τ is proportional to $\sqrt{I(\tau)}$.

The class of priors given by expression (11.2.2) is often called the class of **Jeffreys' priors**; see Jeffreys (1961). This exercise shows that Jeffreys' priors exhibit an invariance in that the prior of a parameter τ , which is a function of θ , is also proportional to the square root of the information for τ .

11.2.5. Consider the Bayes model

$$\begin{aligned} X_i|\theta, i = 1, 2, \dots, n &\sim \text{iid with distribution } \Gamma(1, \theta), \quad \theta > 0 \\ \Theta &\sim h(\theta) \propto \frac{1}{\theta}. \end{aligned}$$

- (a) Show that $h(\theta)$ is in the class of Jeffreys' priors.

- (b) Show that the posterior pdf is

$$h(\theta|y) \propto \left(\frac{1}{\theta} \right)^{n+2-1} e^{-y/\theta},$$

where $y = \sum_{i=1}^n x_i$.

- (c) Show that if $\tau = \theta^{-1}$, then the posterior $k(\tau|y)$ is the pdf of a $\Gamma(n, 1/y)$ distribution.
- (d) Determine the posterior pdf of $2y\tau$. Use it to obtain a $(1 - \alpha)100\%$ credible interval for θ .
- (e) Use the posterior pdf in part (d) to determine a Bayesian test for the hypotheses $H_0 : \theta \geq \theta_0$ versus $H_1 : \theta < \theta_0$, where θ_0 is specified.

11.2.6. Consider the Bayes model

$$\begin{aligned} X_i | \theta, i = 1, 2, \dots, n &\sim \text{iid with distribution Poisson } (\theta), \theta > 0 \\ \Theta &\sim h(\theta) \propto \theta^{-1/2}. \end{aligned}$$

- (a) Show that $h(\theta)$ is in the class of Jeffreys' priors.
- (b) Show that the posterior pdf of $2n\theta$ is the pdf of a $\chi^2(2y + 1)$ distribution, where $y = \sum_{i=1}^n x_i$.
- (c) Use the posterior pdf of part (b) to obtain a $(1 - \alpha)100\%$ credible interval for θ .
- (d) Use the posterior pdf in part (d) to determine a Bayesian test for the hypotheses $H_0 : \theta \geq \theta_0$ versus $H_1 : \theta < \theta_0$, where θ_0 is specified.

11.2.7. Consider the Bayes model

$$X_i | \theta, i = 1, 2, \dots, n \sim \text{iid with distribution } b(1, \theta), 0 < \theta < 1.$$

- (a) Obtain the Jeffreys' prior for this model.
- (b) Assume squared-error loss and obtain the Bayes estimate of θ .

11.2.8. Consider the Bayes model

$$\begin{aligned} X_i | \theta, i = 1, 2, \dots, n &\sim \text{iid with distribution } b(1, \theta), 0 < \theta < 1 \\ \Theta &\sim h(\theta) = 1. \end{aligned}$$

- (a) Obtain the posterior pdf.
- (b) Assume squared-error loss and obtain the Bayes estimate of θ .

11.2.9. Let $\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_n$ be a random sample from a multivariate normal distribution with mean vector $\boldsymbol{\mu} = (\mu_1, \mu_2, \dots, \mu_k)'$ and known positive definite covariance matrix $\boldsymbol{\Sigma}$. Let $\bar{\mathbf{X}}$ be the mean vector of the random sample. Suppose that $\boldsymbol{\mu}$ has a prior multivariate normal distribution with mean $\boldsymbol{\mu}_0$ and positive definite covariance matrix $\boldsymbol{\Sigma}_0$. Find the posterior distribution of $\boldsymbol{\mu}$, given $\bar{\mathbf{X}} = \bar{\mathbf{x}}$. Then find the Bayes estimate $E(\boldsymbol{\mu} | \bar{\mathbf{X}} = \bar{\mathbf{x}})$.

11.3 Gibbs Sampler

From the preceding sections, it is clear that integration techniques play a significant role in Bayesian inference. Hence, we now touch on some of the Monte Carlo techniques used for integration in Bayesian inference.

The Monte Carlo techniques discussed in Chapter 5 can often be used to obtain Bayesian estimates. For example, suppose a random sample is drawn from a

$N(\theta, \sigma^2)$, where σ^2 is known. Then $Y = \bar{X}$ is a sufficient statistic. Consider the Bayes model

$$\begin{aligned} Y|\theta &\sim N(\theta, \sigma^2/n) \\ \Theta &\sim h(\theta) \propto b^{-1} \exp\{-(\theta - a)/b\} / (1 + \exp\{-(\theta - a)/b\})^2, \quad -\infty < \theta < \infty, \\ &a \text{ and } b > 0 \text{ are known,} \end{aligned} \tag{11.3.1}$$

i.e., the prior is a logistic distribution. Thus the posterior pdf is

$$k(\theta|y) = \frac{\frac{1}{\sqrt{2\pi}\sigma/\sqrt{n}} \exp\left\{-\frac{1}{2}\frac{(y-\theta)^2}{\sigma^2/n}\right\} b^{-1} e^{-(\theta-a)/b} / (1 + e^{-(\theta-a)/b})^2}{\int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}\sigma/\sqrt{n}} \exp\left\{-\frac{1}{2}\frac{(y-\theta)^2}{\sigma^2/n}\right\} b^{-1} e^{-(\theta-a)/b} / (1 + e^{-(\theta-a)/b})^2 d\theta}.$$

Assuming squared-error loss, the Bayes estimate is the mean of this posterior distribution. Its computation involves two integrals, which cannot be obtained in closed form. We can, however, think of the integration in the following way. Consider the likelihood $f(y|\theta)$ as a function of θ ; that is, consider the function

$$w(\theta) = f(y|\theta) = \frac{1}{\sqrt{2\pi}\sigma/\sqrt{n}} \exp\left\{-\frac{1}{2}\frac{(y-\theta)^2}{\sigma^2/n}\right\}.$$

We can then write the Bayes estimate as

$$\begin{aligned} \delta(y) &= \frac{\int_{-\infty}^{\infty} \theta w(\theta) b^{-1} e^{-(\theta-a)/b} / (1 + e^{-(\theta-a)/b})^2 d\theta}{\int_{-\infty}^{\infty} w(\theta) b^{-1} e^{-(\theta-a)/b} / (1 + e^{-(\theta-a)/b})^2 d\theta} \\ &= \frac{E[\Theta w(\Theta)]}{E[w(\Theta)]}, \end{aligned} \tag{11.3.2}$$

where the expectation is taken with Θ having the logistic prior distribution.

The estimation can be carried out by simple Monte Carlo. Independently, generate $\Theta_1, \Theta_2, \dots, \Theta_m$ from the logistic distribution with pdf as in (11.3.1). This generation is easily computed because the inverse of the logistic cdf is given by $a + b \log\{u/(1-u)\}$, for $0 < u < 1$. Then form the random variable,

$$T_m = \frac{m^{-1} \sum_{i=1}^m \Theta_i w(\Theta_i)}{m^{-1} \sum_{i=1}^m w(\Theta_i)}. \tag{11.3.3}$$

By the Weak Law of Large Numbers (Theorem 5.1.1) and Slutsky's Theorem (Theorem 5.2.4), $T_m \rightarrow \delta(y)$, in probability. The value of m can be quite large. Thus simple Monte Carlo techniques enable us to compute this Bayes estimate. Note that we can bootstrap this sample to obtain a confidence interval for $E[\Theta w(\Theta)]/E[w(\Theta)]$; see Exercise 11.3.2.

Besides simple Monte Carlo methods, there are other more complicated Monte Carlo procedures that are useful in Bayesian inference. For motivation, consider the case in which we want to generate an observation that has pdf $f_X(x)$, but this generation is somewhat difficult. Suppose, however, that it is easy to generate both Y , with pdf $f_Y(y)$, and an observation from the conditional pdf $f_{X|Y}(x|y)$. As the following theorem shows, if we do these sequentially, then we can easily generate from $f_X(x)$.

Theorem 11.3.1. Suppose we generate random variables by the following algorithm:

1. Generate $Y \sim f_Y(y)$,
2. Generate $X \sim f_{X|Y}(x|Y)$.

Then X has pdf $f_X(x)$.

Proof: To avoid confusion, let T be the random variable generated by the algorithm. We need to show that T has pdf $f_X(x)$. Probabilities of events concerning T are conditional on Y and are taken with respect to the cdf $F_{X|Y}$. Recall that probabilities can always be written as expectations of indicator functions and, hence, for events concerning T , are conditional expectations. In particular, for any $t \in R$,

$$\begin{aligned} P[T \leq t] &= E[F_{X|Y}(t)] \\ &= \int_{-\infty}^{\infty} \left[\int_{-\infty}^t f_{X|Y}(x|y) dx \right] f_Y(y) dy \\ &= \int_{-\infty}^t \left[\int_{-\infty}^{\infty} f_{X|Y}(x|y) f_Y(y) dy \right] dx \\ &= \int_{-\infty}^t \left[\int_{-\infty}^{\infty} f_{X,Y}(x,y) dy \right] dx \\ &= \int_{-\infty}^t f_X(x) dx. \end{aligned}$$

Hence the random variable generated by the algorithm has pdf $f_X(x)$, as was to be shown. ■

In the situation of this theorem, suppose we want to determine $E[W(X)]$, for some function $W(x)$, where $E[W^2(X)] < \infty$. Using the algorithm of the theorem, generate independently the sequence $(Y_1, X_1), (Y_2, X_2), \dots, (Y_m, X_m)$, for a specified value of m , where Y_i is drawn from the pdf $f_Y(y)$ and X_i is generated from the pdf $f_{X|Y}(x|Y)$. Then by the Weak Law of Large Numbers,

$$\bar{W} = \frac{1}{m} \sum_{i=1}^m W(X_i) \xrightarrow{P} \int_{-\infty}^{\infty} W(x) f_X(x) dx = E[W(X)].$$

Furthermore, by the Central Limit Theorem, $\sqrt{m}(\bar{W} - E[W(X)])$ converges in distribution to a $N(0, \sigma_W^2)$ distribution, where $\sigma_W^2 = \text{Var}(W(X))$. If w_1, w_2, \dots, w_m is a realization of such a random sample, then an approximate $(1 - \alpha)100\%$ (large sample) confidence interval for $E[W(X)]$ is

$$\bar{w} \pm z_{\alpha/2} \frac{s_W}{\sqrt{m}}, \quad (11.3.4)$$

where $s_W^2 = (m-1)^{-1} \sum_{i=1}^m (w_i - \bar{w})^2$.

To set ideas, we present the following simple example.

Example 11.3.1. Suppose the random variable X has pdf

$$f_X(x) = \begin{cases} 2e^{-x}(1 - e^{-x}) & 0 < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (11.3.5)$$

Suppose Y and $X|Y$ have the respective pdfs

$$f_Y(y) = \begin{cases} 2e^{-2y} & 0 < y < \infty \\ 0 & \text{elsewhere} \end{cases} \quad (11.3.6)$$

$$f_{X|Y}(x|y) = \begin{cases} e^{-(x-y)} & y < x < \infty \\ 0 & \text{elsewhere.} \end{cases} \quad (11.3.7)$$

Suppose we generate random variables by the following algorithm:

1. Generate $Y \sim f_Y(y)$ as in expression (11.3.6).
2. Generate $X \sim f_{X|Y}(x|Y)$ as in expression (11.3.7).

Then, by Theorem 11.3.1, X has the pdf (11.3.5). Furthermore, it is easy to generate from the pdfs (11.3.6) and (11.3.7) because the inverses of the respective cdfs are given by $F_Y^{-1}(u) = -2^{-1} \log(1 - u)$ and $F_{X|Y}^{-1}(u) = -\log(1 - u) + Y$.

As a numerical illustration, the R function `condsim1` (found at the site listed in the Preface) uses this algorithm to generate observations from the pdf (11.3.5). Using this function, we performed $m = 10,000$ simulations of the algorithm. The sample mean and standard deviation were $\bar{x} = 1.495$ and $s = 1.112$. Hence a 95% confidence interval for $E(X)$ is $(1.473, 1.517)$, which traps the true value $E(X) = 1.5$; see Exercise 11.3.4. ■

For the last example, Exercise 11.3.3 establishes the joint distribution of (X, Y) and shows that the marginal pdf of X is given by (11.3.5). Furthermore, as shown in this exercise, it is easy to generate from the distribution of X directly. In Bayesian inference, though, we are often dealing with conditional pdfs, and theorems such as Theorem 11.3.1 are quite useful.

The main purpose of presenting this algorithm is to motivate another algorithm, called the **Gibbs Sampler**, which is useful in Bayes methodology. We describe it in terms of two random variables. Suppose (X, Y) has pdf $f(x, y)$. Our goal is to generate two streams of iid random variables, one on X and the other on Y . The Gibbs sampler algorithm is:

Algorithm 11.3.1 (Gibbs Sampler). *Let m be a positive integer, and let X_0 , an initial value, be given. Then for $i = 1, 2, 3, \dots, m$,*

1. Generate $Y_i|X_{i-1} \sim f(y|x)$.
2. Generate $X_i|Y_i \sim f(x|y)$.

Note that before entering the i th step of the algorithm, we have generated X_{i-1} . Let x_{i-1} denote the observed value of X_{i-1} . Then, using this value, generate sequentially the new Y_i from the pdf $f(y|x_{i-1})$ and then draw (the new) X_i from the

pdf $f(x|y_i)$, where y_i is the observed value of Y_i . In advanced texts, it is shown that

$$\begin{aligned} Y_i &\xrightarrow{D} Y \sim f_Y(y) \\ X_i &\xrightarrow{D} X \sim f_X(x), \end{aligned} \quad (11.3.8)$$

as $i \rightarrow \infty$, and

$$\frac{1}{m} \sum_{i=1}^m W(X_i) \xrightarrow{P} E[W(X)], \text{ as } m \rightarrow \infty. \quad (11.3.9)$$

Note that the Gibbs sampler is similar but not quite the same as the algorithm given by Theorem 11.3.1. Consider the sequence of generated pairs

$$(X_1, Y_1), (X_2, Y_2), \dots, (X_k, Y_k), (X_{k+1}, Y_{k+1}).$$

Note that to compute (X_{k+1}, Y_{k+1}) , we need only the pair (X_k, Y_k) and none of the previous pairs from 1 to $k - 1$. That is, given the present state of the sequence, the future of the sequence is independent of the past. In stochastic processes such a sequence is called a **Markov chain**. Under general conditions, the distribution of Markov chains stabilizes (reaches an equilibrium or steady-state distribution) as the length of the chain increases. For the Gibbs sampler, the equilibrium distributions are the limiting distributions in the expression (11.3.8) as $i \rightarrow \infty$. How large should i be? In practice, usually the chain is allowed to run to some large value i before recording the observations. Furthermore, several recordings are run with this value of i and the resulting empirical distributions of the generated random observations are examined for their similarity. Also, the starting value for X_0 is needed; see Casella and George (1992) for a discussion. The theory behind the convergences given in the expression (11.3.8) is beyond the scope of this text. There are many excellent references on this theory. A discussion from an elementary level can be found in Casella and George (1992). An informative overview can be found in Chapter 7 of Robert and Casella (1999); see also Lehmann and Casella (1998). We next provide a simple example.

Example 11.3.2. Suppose (X, Y) has the mixed discrete-continuous pdf given by

$$f(x, y) = \begin{cases} \frac{1}{\Gamma(\alpha)} \frac{1}{x!} y^{\alpha+x-1} e^{-2y} & y > 0; x = 0, 1, 2, \dots \\ 0 & \text{elsewhere,} \end{cases} \quad (11.3.10)$$

for $\alpha > 0$. Exercise 11.3.5 shows that this is a pdf and obtains the marginal pdfs. The conditional pdfs, however, are given by

$$f(y|x) \propto y^{\alpha+x-1} e^{-2y} \quad (11.3.11)$$

and

$$f(x|y) \propto e^{-y} \frac{y^x}{x!}. \quad (11.3.12)$$

Hence the conditional densities are $\Gamma(\alpha+x, 1/2)$ and Poisson (y), respectively. Thus the Gibbs sampler algorithm is, for $i = 1, 2, \dots, m$,

1. Generate $Y_i|X_{i-1} \sim \Gamma(\alpha + X_{i-1}, 1/2)$.
2. Generate $X_i|Y_i \sim \text{Poisson}(Y_i)$.

In particular, for large m and $n > m$,

$$\bar{Y} = (n-m)^{-1} \sum_{i=m+1}^n Y_i \xrightarrow{P} E(Y) \quad (11.3.13)$$

$$\bar{X} = (n-m)^{-1} \sum_{i=m+1}^n X_i \xrightarrow{P} E(X). \quad (11.3.14)$$

In this case, it can be shown (see Exercise 11.3.5) that both expectations are equal to α . The R function `gibbsr2.s`, found at the site listed in the Preface, computes this Gibbs sampler. Using this routine, the authors obtained the following results upon setting $\alpha = 10$, $m = 3000$, and $n = 6000$:

Parameter	Estimate	Sample Estimate	Sample Variance	Approximate 95% Confidence Interval
$E(Y) = \alpha = 10$	\bar{y}	10.027	10.775	(9.910, 10.145)
$E(X) = \alpha = 10$	\bar{x}	10.061	21.191	(9.896, 10.225)

where the estimates \bar{y} and \bar{x} are the observed values of the estimators in expressions (11.3.13) and (11.3.14), respectively. The confidence intervals for α are the large sample confidence intervals for means discussed in Example 4.2.2, using the sample variances found in the fourth column of the above table. Note that both confidence intervals trapped $\alpha = 10$. ■

EXERCISES

11.3.1. Suppose Y has a $\Gamma(1, 1)$ distribution while X given Y has the conditional pdf

$$f(x|y) = \begin{cases} e^{-(x-y)} & 0 < y < x < \infty \\ 0 & \text{elsewhere.} \end{cases}$$

Note that both the pdf of Y and the conditional pdf are easy to simulate.

- (a) Set up the algorithm of Theorem 11.3.1 to generate a stream of iid observations with pdf $f_X(x)$.
- (b) State how to estimate $E(X)$.
- (c) Using your algorithm found in part (a), write an R function to estimate $E(X)$.
- (d) Using your program, obtain a stream of 2000 simulations. Compute your estimate of $E(X)$ and find an approximate 95% confidence interval.
- (e) Show that X has a $\Gamma(2, 1)$ distribution. Did your confidence interval trap the true value 2?

11.3.2. Carefully write down the algorithm to obtain a bootstrap percentile confidence interval for $E[\Theta w(\Theta)]/E[w(\Theta)]$, using the sample $\Theta_1, \Theta_2, \dots, \Theta_m$ and the estimator given in expression (11.3.3). Write R code for this bootstrap.

11.3.3. Consider Example 11.3.1.

- (a) Show that $E(X) = 1.5$.
- (b) Obtain the inverse of the cdf of X and use it to show how to generate X directly.

11.3.4. Obtain another 10,000 simulations similar to those discussed at the end of Example 11.3.1. Use your simulations to obtain a confidence interval for $E(X)$.

11.3.5. Consider Example 11.3.2.

- (a) Show that the function given in expression (11.3.10) is a joint, mixed discrete-continuous pdf.
- (b) Show that the random variable Y has a $\Gamma(\alpha, 1)$ distribution.
- (c) Show that the random variable X has a negative binomial distribution with pmf

$$p(x) = \begin{cases} \frac{(\alpha+x-1)!}{x!(\alpha-1)!} 2^{-(\alpha+x)} & x = 0, 1, 2, \dots \\ 0 & \text{elsewhere.} \end{cases}$$

- (d) Show that $E(X) = \alpha$.

11.3.6. Write an R function (or use `gibbsr2.s`) for the Gibbs sampler discussed in Example 11.3.2. Run your function for $\alpha = 10$, $m = 3000$, and $n = 6000$. Compare your results with those of the authors tabled in the example.

11.3.7. Consider the following mixed discrete-continuous pdf for a random vector (X, Y) (discussed in Casella and George, 1992):

$$f(x, y) \propto \begin{cases} \binom{n}{x} y^x (1-y)^{n-x} & x = 0, 1, \dots, n, 0 < y < 1 \\ 0 & \text{elsewhere,} \end{cases}$$

for $\alpha > 0$ and $\beta > 0$.

- (a) Show that this function is indeed a joint, mixed discrete-continuous pdf by finding the proper constant of proportionality.
- (b) Determine the conditional pdfs $f(x|y)$ and $f(y|x)$.
- (c) Write the Gibbs sampler algorithm to generate random samples on X and Y .
- (d) Determine the marginal distributions of X and Y .

11.3.8. Write an R function for the Gibbs sampler of Exercise 11.3.7. Run your program for $\alpha = 10$, $\beta = 4$, $m = 3000$, and $n = 6000$. Obtain estimates (and confidence intervals) of $E(X)$ and $E(Y)$ and compare them with the true parameters.

11.4 Modern Bayesian Methods

The prior pdf has an important influence in Bayesian inference. We need only consider the different Bayes estimators for the normal model based on different priors, as shown in Examples 11.1.3 and 11.2.1. One way of having more control over the prior is to model the prior in terms of another random variable. This is called the **hierarchical Bayes** model, and it is of the form

$$\begin{aligned} X|\theta &\sim f(x|\theta) \\ \Theta|\gamma &\sim h(\theta|\gamma) \\ \Gamma &\sim \psi(\gamma). \end{aligned} \quad (11.4.1)$$

With this model we can exert control over the prior $h(\theta|\gamma)$ by modifying the pdf of the random variable Γ . A second methodology, **empirical Bayes**, obtains an estimate of γ and plugs it into the posterior pdf. We offer the reader a brief introduction of these procedures in this section. There are several good books on Bayesian methods. In particular, Chapter 4 of Lehmann and Casella (1998) discusses these procedures in some detail.

Consider first the hierarchical Bayes model given by (11.4.1). The parameter γ can be thought of a nuisance parameter. It is often called a **hyperparameter**. As with regular Bayes, the inference focuses on the parameter θ ; hence, the posterior pdf of interest remains the conditional pdf $k(\theta|x)$.

These discussions often involve several pdfs; hence, we frequently use g as a generic pdf. It will always be clear from its arguments what distribution it represents. Keep in mind that the conditional pdf $f(x|\theta)$ does not depend on γ ; hence,

$$\begin{aligned} g(\theta, \gamma|x) &= \frac{g(x, \theta, \gamma)}{g(x)} \\ &= \frac{g(x|\theta, \gamma)g(\theta, \gamma)}{g(x)} \\ &= \frac{f(x|\theta)h(\theta|\gamma)\psi(\gamma)}{g(x)}. \end{aligned}$$

Therefore, the posterior pdf is given by

$$k(\theta|x) = \frac{\int_{-\infty}^{\infty} f(x|\theta)h(\theta|\gamma)\psi(\gamma) d\gamma}{\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x|\theta)h(\theta|\gamma)\psi(\gamma) d\gamma d\theta}. \quad (11.4.2)$$

Furthermore, assuming squared-error loss, the Bayes estimate of $W(\theta)$ is

$$\delta_W(x) = \frac{\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} W(\theta)f(x|\theta)h(\theta|\gamma)\psi(\gamma) d\gamma d\theta}{\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x|\theta)h(\theta|\gamma)\psi(\gamma) d\gamma d\theta}. \quad (11.4.3)$$

Recall that we defined the Gibbs sampler in Section 11.3. Here we describe it to obtain the Bayes estimate of $W(\theta)$. For $i = 1, 2, \dots, m$, where m is specified, the

i th step of the algorithm is

$$\begin{aligned}\Theta_i | \mathbf{x}, \gamma_{i-1} &\sim g(\theta | \mathbf{x}, \gamma_{i-1}) \\ \Gamma_i | \mathbf{x}, \theta_i &\sim g(\gamma | \mathbf{x}, \theta_i).\end{aligned}$$

Recall from our discussion in Section 11.3 that

$$\begin{aligned}\Theta_i &\xrightarrow{D} k(\theta | \mathbf{x}) \\ \Gamma_i &\xrightarrow{D} g(\gamma | \mathbf{x}),\end{aligned}$$

as $i \rightarrow \infty$. Furthermore, the arithmetic average

$$\frac{1}{m} \sum_{i=1}^m W(\Theta_i) \xrightarrow{P} E[W(\Theta) | \mathbf{x}] = \delta_W(\mathbf{x}) \text{ as } m \rightarrow \infty. \quad (11.4.4)$$

In practice, to obtain the Bayes estimate of $W(\theta)$ by the Gibbs sampler, we generate by Monte Carlo the stream of values $(\theta_1, \gamma_1), (\theta_2, \gamma_2), \dots$. Then choosing large values of m and $n^* > m$, our estimate of $W(\theta)$ is the average,

$$\frac{1}{n^* - m} \sum_{i=m+1}^{n^*} W(\theta_i). \quad (11.4.5)$$

Because of the Monte Carlo generation these procedures are often called **MCMC**, for **Markov Chain Monte Carlo** procedures. We next provide two examples.

Example 11.4.1. Reconsider the conjugate family of normal distributions discussed in Example 11.1.3, with $\theta_0 = 0$. Here we use the model

$$\begin{aligned}\bar{X} | \Theta &\sim N\left(\theta, \frac{\sigma^2}{n}\right), \sigma^2 \text{ is known} \\ \Theta | \tau^2 &\sim N(0, \tau^2) \\ \frac{1}{\tau^2} &\sim \Gamma(a, b), a \text{ and } b \text{ are known.}\end{aligned} \quad (11.4.6)$$

To set up the Gibbs sampler for this hierarchical Bayes model, we need the conditional pdfs $g(\theta | \bar{x}, \tau^2)$ and $g(\tau^2 | \bar{x}, \theta)$. For the first, we have

$$g(\theta | \bar{x}, \tau^2) \propto f(\bar{x} | \theta) h(\theta | \tau^2) \psi(\tau^{-2}).$$

As we have been doing, we can ignore standardizing constants; hence, we need only consider the product $f(\bar{x} | \theta) h(\theta | \tau^2)$. But this is a product of two normal pdfs which we obtained in Example 11.1.3. Based on those results, $g(\theta | \bar{x}, \tau^2)$ is the pdf of a $N(\{\tau^2 / [(\sigma^2/n) + \tau^2]\} \bar{x}, (\tau^2 \sigma^2) / [\sigma^2 + n\tau^2])$. For the second pdf, by ignoring standardizing constants and simplifying, we obtain

$$\begin{aligned}g\left(\frac{1}{\tau^2} | \bar{x}, \theta\right) &\propto f(\bar{x} | \theta) g(\theta | \tau^2) \psi(1/\tau^2) \\ &\propto \frac{1}{\tau} \exp\left\{-\frac{1}{2} \frac{\theta^2}{\tau^2}\right\} \left(\frac{1}{\tau^2}\right)^{a-1} \exp\left\{-\frac{1}{\tau^2} \frac{1}{b}\right\} \\ &\propto \left(\frac{1}{\tau^2}\right)^{a+(1/2)-1} \exp\left\{-\frac{1}{\tau^2} \left[\frac{\theta^2}{2} + \frac{1}{b}\right]\right\},\end{aligned} \quad (11.4.7)$$

which is the pdf of a $\Gamma\{a + (1/2), [(\theta^2/2) + (1/b)]^{-1}\}$ distribution. Thus the Gibbs sampler for this model is given by:

$$\begin{aligned}\Theta_i | \bar{x}, \tau_{i-1}^2 &\sim N\left(\frac{\tau_{i-1}^2}{(\sigma^2/n) + \tau_{i-1}^2} \bar{x}, \frac{\tau_{i-1}^2 \sigma^2}{\sigma^2 + n\tau_{i-1}^2}\right) \\ \frac{1}{\tau_i^2} | \bar{x}, \Theta_i &\sim \Gamma\left(a + \frac{1}{2}, \left(\frac{\theta_i^2}{2} + \frac{1}{b}\right)^{-1}\right),\end{aligned}\quad (11.4.8)$$

for $i = 1, 2, \dots, m$. As discussed above, for a specified values of large m and $n^* > m$, we collect the chain's values $((\Theta_m, \tau_m), (\Theta_{m+1}, \tau_{m+1}), \dots, (\Theta_{n^*}, \tau_{n^*}))$ and then obtain the Bayes estimate of θ (assuming squared-error loss):

$$\hat{\theta} = \frac{1}{n^* - m} \sum_{i=m+1}^{n^*} \Theta_i. \quad (11.4.9)$$

The conditional distribution of Θ given \bar{x} and τ_{i-1} , though, suggests the second estimate given by

$$\hat{\theta}^* = \frac{1}{n^* - m} \sum_{i=m+1}^{n^*} \frac{\tau_i^2}{\tau_i^2 + (\sigma^2/n)} \bar{x}. \quad \blacksquare \quad (11.4.10)$$

Example 11.4.2. Lehmann and Casella (1998, p. 257) presented the following hierarchical Bayes model:

$$\begin{aligned}X|\lambda &\sim \text{Poisson}(\lambda) \\ \Lambda|b &\sim \Gamma(1, b) \\ B &\sim g(b) = \tau^{-1}b^{-2} \exp\{-1/b\tau\}, \quad b > 0, \tau > 0.\end{aligned}$$

For the Gibbs sampler, we need the two conditional pdfs, $g(\lambda|x, b)$ and $g(b|x, \lambda)$. The joint pdf is

$$g(x, \lambda, b) = f(x|\lambda)h(\lambda|b)\psi(b). \quad (11.4.11)$$

Based on the pdfs of the model, (11.4.11), for the first conditional pdf we have

$$\begin{aligned}g(\lambda|x, b) &\propto e^{-\lambda} \frac{\lambda^x}{x!} \frac{1}{b} e^{-\lambda/b} \\ &\propto \lambda^{x+1-1} e^{-\lambda[1+(1/b)]},\end{aligned}\quad (11.4.12)$$

which is the pdf of a $\Gamma(x + 1, b/[b + 1])$ distribution.

For the second conditional pdf, we have

$$\begin{aligned}g(b|x, \lambda) &\propto \frac{1}{b} e^{-\lambda/b} \tau^{-1} b^{-2} e^{-1/(b\tau)} \\ &\propto b^{-3} \exp\left\{-\frac{1}{b} \left[\frac{1}{\tau} + \lambda\right]\right\}.\end{aligned}$$

In this last expression, making the change of variable $y = 1/b$ which has the Jacobian $db/dy = -y^{-2}$, we obtain

$$\begin{aligned} g(y|x, \lambda) &\propto y^3 \exp\left\{-y\left[\frac{1}{\tau} + \lambda\right]\right\} y^{-2} \\ &\propto y^{2-1} \exp\left\{-y\left[\frac{1 + \lambda\tau}{\tau}\right]\right\}, \end{aligned}$$

which is easily seen to be the pdf of the $\Gamma(2, \tau/[\lambda\tau + 1])$ distribution. Therefore, the Gibbs sampler is, for $i = 1, 2, \dots, m$, where m is specified,

$$\begin{aligned} \Lambda_i|x, b_{i-1} &\sim \Gamma(x+1, b_{i-1}/[1+b_{i-1}]) \\ B_i = Y_i^{-1}, \text{ where } Y_i|x, \lambda_i &\sim \Gamma(2, \tau/[\lambda_i\tau + 1]). \blacksquare \end{aligned}$$

As a numerical illustration of the last example, suppose we set $\tau = 0.05$ and observe $x = 6$. The R function¹ `hierarch1.s` computes the Gibbs sampler given in the example. It requires specification of the value of i at which the Gibbs sample commences and the length of the chain beyond this point. We set these values at $m = 1000$ and $n^* = 4000$, respectively, i.e., the length of the chain used in the estimate is 3000. To see the effect that varying τ has on the Bayes estimator, we performed five Gibbs samplers, with these results:

τ	0.040	0.045	0.050	0.055	0.060
$\hat{\delta}$	6.600	6.490	6.530	6.500	6.440

There is some variation. As discussed in Lehmann and Casella (1998), in general, there is less effect on the Bayes estimator due to variability of the hyperparameter than in regular Bayes due to the variance of the prior.

11.4.1 Empirical Bayes

The empirical Bayes model consists of the first two lines of the hierarchical Bayes model; i.e.,

$$\begin{aligned} \mathbf{X}|\theta &\sim f(\mathbf{x}|\theta) \\ \Theta|\gamma &\sim h(\theta|\gamma). \end{aligned}$$

Instead of attempting to model the parameter γ with a pdf as in hierarchical Bayes, empirical Bayes methodology estimates γ based on the data as follows. Recall that

$$\begin{aligned} g(\mathbf{x}, \theta|\gamma) &= \frac{g(\mathbf{x}, \theta, \gamma)}{\psi(\gamma)} \\ &= \frac{f(\mathbf{x}|\theta)h(\theta|\gamma)\psi(\gamma)}{\psi(\gamma)} \\ &= f(\mathbf{x}|\theta)h(\theta|\gamma). \end{aligned}$$

¹Downloadable at the site listed in the Preface

Consider, then, the likelihood function

$$m(\mathbf{x}|\gamma) = \int_{-\infty}^{\infty} f(\mathbf{x}|\theta)h(\theta|\gamma) d\theta. \quad (11.4.13)$$

Using the pdf $m(\mathbf{x}|\gamma)$, we obtain an estimate $\hat{\gamma} = \hat{\gamma}(\mathbf{x})$, usually by the method of maximum likelihood. For inference on the parameter θ , the empirical Bayes procedure uses the posterior pdf $k(\theta|\mathbf{x}, \hat{\gamma})$.

We illustrate the empirical Bayes procedure with the following example.

Example 11.4.3. Consider the same situation discussed in Example 11.4.2, except assume that we have a random sample on X ; i.e., consider the model

$$\begin{aligned} X_i|\lambda, i = 1, 2, \dots, n &\sim \text{iid Poisson}(\lambda) \\ \Lambda|b &\sim \Gamma(1, b). \end{aligned}$$

Let $\mathbf{X} = (X_1, X_2, \dots, X_n)'$. Hence,

$$g(\mathbf{x}|\lambda) = \frac{\lambda^{n\bar{x}}}{x_1! \cdots x_n!} e^{-n\lambda},$$

where $\bar{x} = n^{-1} \sum_{i=1}^n x_i$. Thus, the pdf we need to maximize is

$$\begin{aligned} m(\mathbf{x}|b) &= \int_0^{\infty} g(\mathbf{x}|\lambda)h(\lambda|b) d\lambda \\ &= \int_0^{\infty} \frac{1}{x_1! \cdots x_n!} \lambda^{n\bar{x}+1-1} e^{-n\lambda} \frac{1}{b} e^{-\lambda/b} d\lambda \\ &= \frac{\Gamma(n\bar{x}+1)[b/(nb+1)]^{n\bar{x}+1}}{x_1! \cdots x_n! b}. \end{aligned}$$

Taking the partial derivative of $\log m(\mathbf{x}|b)$ with respect to b , we obtain

$$\frac{\partial \log m(\mathbf{x}|b)}{\partial b} = -\frac{1}{b} + (n\bar{x}+1) \frac{1}{b(bn+1)}.$$

Setting this equal to 0 and solving for b , we obtain the solution

$$\hat{b} = \bar{x}. \quad (11.4.14)$$

To obtain the empirical Bayes estimate of λ , we need to compute the posterior pdf with \hat{b} substituted for b . The posterior pdf is

$$\begin{aligned} k(\lambda|\mathbf{x}, \hat{b}) &\propto g(\mathbf{x}|\lambda)h(\lambda|\hat{b}) \\ &\propto \lambda^{n\bar{x}+1-1} e^{-\lambda[n+(1/\hat{b})]}, \end{aligned} \quad (11.4.15)$$

which is the pdf of a $\Gamma(n\bar{x}+1, \hat{b}/[n\hat{b}+1])$ distribution. Therefore, the empirical Bayes estimator under squared-error loss is the mean of this distribution; i.e.,

$$\hat{\lambda} = [n\bar{x}+1] \frac{\hat{b}}{n\hat{b}+1} = \bar{x}, \quad (11.4.16)$$

since $\hat{b} = \bar{x}$. Thus, for the above prior, the empirical Bayes estimate agrees with the mle. ■

We can use our solution of this last example to obtain the empirical Bayes estimate for Example 11.4.2 also, for in this earlier example, the sample size is 1. Thus, the empirical Bayes estimate for λ is x . In particular, for the numerical case given at the end of Example 11.4.2, the empirical Bayes estimate has the value 6.

EXERCISES

11.4.1. Consider the Bayes model

$$\begin{aligned} X_i|\theta &\sim \text{iid } \Gamma\left(1, \frac{1}{\theta}\right) \\ \Theta|\beta &\sim \Gamma(2, \beta). \end{aligned}$$

By performing the following steps, obtain the empirical Bayes estimate of θ .

(a) Obtain the likelihood function

$$m(\mathbf{x}|\beta) = \int_0^\infty f(\mathbf{x}|\theta)h(\theta|\beta) d\theta.$$

(b) Obtain the mle $\hat{\beta}$ of β for the likelihood $m(\mathbf{x}|\beta)$.

(c) Show that the posterior distribution of Θ given \mathbf{x} and $\hat{\beta}$ is a gamma distribution.

(d) Assuming squared-error loss, obtain the empirical Bayes estimator.

11.4.2. Consider the hierarchical Bayes model

$$\begin{aligned} Y &\sim b(n, p), \quad 0 < p < 1 \\ p|\theta &\sim h(p|\theta) = \theta p^{\theta-1}, \quad \theta > 0 \\ \theta &\sim \Gamma(1, a), \quad a > 0 \text{ is specified.} \end{aligned} \tag{11.4.17}$$

(a) Assuming squared-error loss, write the Bayes estimate of p as in expression (11.4.3). Integrate relative to θ first. Show that both the numerator and denominator are expectations of a beta distribution with parameters $y + 1$ and $n - y + 1$.

(b) Recall the discussion around expression (11.3.2). Write an explicit Monte Carlo algorithm to obtain the Bayes estimate in part (a).

11.4.3. Reconsider the hierarchical Bayes model (11.4.17) of Exercise 11.4.2.

(a) Show that the conditional pdf $g(p|y, \theta)$ is the pdf of a beta distribution with parameters $y + \theta$ and $n - y + 1$.

(b) Show that the conditional pdf $g(\theta|y, p)$ is the pdf of a gamma distribution with parameters 2 and $\left[\frac{1}{a} - \log p\right]^{-1}$.

- (c) Using parts (a) and (b) and assuming squared-error loss, write the Gibbs sampler algorithm to obtain the Bayes estimator of p .

11.4.4. For the hierarchical Bayes model of Exercise 11.4.2, set $n = 50$ and $a = 2$. Now, draw a θ at random from a $\Gamma(1, 2)$ distribution and label it θ^* . Next, draw a p at random from the distribution with pdf $\theta^* p^{\theta^*-1}$ and label it p^* . Finally, draw a y at random from a $b(n, p^*)$ distribution.

- (a) Setting m at 3000, obtain an estimate of θ^* using your Monte Carlo algorithm of Exercise 11.4.2.
- (b) Setting m at 3000 and n^* at 6000, obtain an estimate of θ^* using your Gibbs sampler algorithm of Exercise 11.4.3. Let $p_{3001}, p_{3002}, \dots, p_{6000}$ denote the stream of values drawn. Recall that these values are (asymptotically) simulated values from the posterior pdf $g(p|y)$. Use this stream of values to obtain a 95% credible interval.

11.4.5. Write the Bayes model of Exercise 11.4.2 as

$$\begin{aligned} Y &\sim b(n, p), \quad 0 < p < 1 \\ p|\theta &\sim h(p|\theta) = \theta p^{\theta-1}, \quad \theta > 0. \end{aligned}$$

Set up the estimating equations for the mle of $g(y|\theta)$, i.e., the first step to obtain the empirical Bayes estimator of p . Simplify as much as possible.

11.4.6. Example 11.4.1 dealt with a hierarchical Bayes model for a conjugate family of normal distributions. Express that model as

$$\begin{aligned} \bar{X}|\Theta &\sim N\left(\theta, \frac{\sigma^2}{n}\right), \quad \sigma^2 \text{ is known} \\ \Theta|\tau^2 &\sim N(0, \tau^2). \end{aligned}$$

Obtain the empirical Bayes estimator of θ .

Mathematical Comments

A.1 Regularity Conditions

These are the regularity conditions referred to in Sections 6.4 and 6.5 of the text. A discussion of these conditions can be found in Chapter 6 of Lehmann and Casella (1998).

Let X have pdf $f(x; \boldsymbol{\theta})$, where $\boldsymbol{\theta} \in \Omega \subset R^p$. For these assumptions, X can be either a scalar random variable or a random vector in R^k . As in Section 6.4, let $\mathbf{I}(\boldsymbol{\theta}) = [I_{jk}]$ denote the $p \times p$ information matrix given by expression (6.4.4). Also, we will denote the true parameter $\boldsymbol{\theta}$ by $\boldsymbol{\theta}_0$.

Assumptions A.1.1. *Additional regularity conditions for Sections 6.4 and 6.5.*

(R6): *There exists an open subset $\Omega_0 \subset \Omega$ such that $\boldsymbol{\theta}_0 \in \Omega_0$ and all third partial derivatives of $f(x; \boldsymbol{\theta})$ exist for all $\boldsymbol{\theta} \in \Omega_0$.*

(R7) *The following equations are true (essentially, we can interchange expectation and differentiation):*

$$\begin{aligned} E_{\boldsymbol{\theta}} \left[\frac{\partial}{\partial \theta_j} \log f(x; \boldsymbol{\theta}) \right] &= 0, \quad \text{for } j = 1, \dots, p \\ I_{jk}(\boldsymbol{\theta}) &= E_{\boldsymbol{\theta}} \left[-\frac{\partial^2}{\partial \theta_j \partial \theta_k} \log f(x; \boldsymbol{\theta}) \right], \quad \text{for } j, k = 1, \dots, p. \end{aligned}$$

(R8) *For all $\boldsymbol{\theta} \in \Omega_0$, $\mathbf{I}(\boldsymbol{\theta})$ is positive definite.*

(R9) *There exist functions $M_{jkl}(x)$ such that*

$$\left| \frac{\partial^3}{\partial \theta_j \partial \theta_k \partial \theta_l} \log f(x; \boldsymbol{\theta}) \right| \leq M_{jkl}(x), \quad \text{for all } \boldsymbol{\theta} \in \Omega_0,$$

and

$$E_{\boldsymbol{\theta}_0}[M_{jkl}] < \infty, \quad \text{for all } j, k, l \in 1, \dots, p. \blacksquare$$

A.2 Sequences

The following is a short review of sequences of real numbers. In particular the liminf and limsup of sequences are discussed. As a supplement to this text, the authors offer a mathematical primer which can be downloaded at the site listed in the Preface. In addition to the following review of sequences, it contains a brief review of infinite series, and differentiable and integrable calculus including double integration. Students that need a review of these concepts can freely download this supplement.

Let $\{a_n\}$ be a sequence of real numbers. Recall from calculus that $a_n \rightarrow a$ ($\lim_{n \rightarrow \infty} a_n = a$) if and only if

$$\text{for every } \epsilon > 0, \text{ there exists an } N_0 \text{ such that } n \geq N_0 \implies |a_n - a| < \epsilon. \quad (\text{A.2.1})$$

Let A be a set of real numbers that is bounded from above; that is, there exists an $M \in R$ such that $x \leq M$ for all $x \in A$. Recall that a is the **supremum** of A if a is the least of all upper bounds of A . From calculus, we know that the supremum of a set bounded from above exists. Furthermore, we know that a is the supremum of A if and only if, for all $\epsilon > 0$, there exists an $x \in A$ such that $a - \epsilon < x \leq a$. Similarly, we can define the **infimum** of A .

We need three additional facts from calculus. The first is the Sandwich Theorem.

Theorem A.2.1 (Sandwich Theorem). *Suppose for sequences $\{a_n\}$, $\{b_n\}$, and $\{c_n\}$ that $c_n \leq a_n \leq b_n$, for all n , and that $\lim_{n \rightarrow \infty} b_n = \lim_{n \rightarrow \infty} c_n = a$. Then $\lim_{n \rightarrow \infty} a_n = a$.*

Proof: Let $\epsilon > 0$ be given. Because both $\{b_n\}$ and $\{c_n\}$ converge, we can choose N_0 so large that $|c_n - a| < \epsilon$ and $|b_n - a| < \epsilon$, for $n \geq N_0$. Because $c_n \leq a_n \leq b_n$, it is easy to see that

$$|a_n - a| \leq \max\{|c_n - a|, |b_n - a|\},$$

for all n . Hence, if $n \geq N_0$, then $|a_n - a| < \epsilon$. ■

The second fact concerns subsequences. Recall that $\{a_{n_k}\}$ is a subsequence of $\{a_n\}$ if the sequence $n_1 \leq n_2 \leq \dots$ is an infinite subset of the positive integers. Note that $n_k \geq k$.

Theorem A.2.2. *The sequence $\{a_n\}$ converges to a if and only if every subsequence $\{a_{n_k}\}$ converges to a .*

Proof: Suppose the sequence $\{a_n\}$ converges to a . Let $\{a_{n_k}\}$ be any subsequence. Let $\epsilon > 0$ be given. Then there exists an N_0 such that $|a_n - a| < \epsilon$, for $n \geq N_0$. For the subsequence, take k' to be the first index of the subsequence beyond N_0 . Because for all k , $n_k \geq k$, we have that $n_k \geq n_{k'} \geq k' \geq N_0$, which implies that $|a_{n_k} - a| < \epsilon$. Thus, $\{a_{n_k}\}$ converges to a . The converse is immediate because a sequence is also a subsequence of itself. ■

Finally, the third theorem concerns monotonic sequences.

Theorem A.2.3. Let $\{a_n\}$ be a nondecreasing sequence of real numbers; i.e., for all n , $a_n \leq a_{n+1}$. Suppose $\{a_n\}$ is bounded from above; i.e., for some $M \in R$, $a_n \leq M$ for all n . Then the limit of a_n exists.

Proof: Let a be the supremum of $\{a_n\}$. Let $\epsilon > 0$ be given. Then there exists an N_0 such that $a - \epsilon < a_{N_0} \leq a$. Because the sequence is nondecreasing, this implies that $a - \epsilon < a_n \leq a$, for all $n \geq N_0$. Hence, by definition, $a_n \rightarrow a$. ■

Let $\{a_n\}$ be a sequence of real numbers and define the two subsequences

$$b_n = \sup\{a_n, a_{n+1}, \dots\}, \quad n = 1, 2, 3, \dots \quad (\text{A.2.2})$$

$$c_n = \inf\{a_n, a_{n+1}, \dots\}, \quad n = 1, 2, 3, \dots \quad (\text{A.2.3})$$

It is obvious that $\{b_n\}$ is a nonincreasing sequence. Hence, if $\{a_n\}$ is bounded from below, then the limit of b_n exists. In this case, we call the limit of $\{b_n\}$ the **limit supremum** (\limsup) of the sequence $\{a_n\}$ and write it as

$$\overline{\lim}_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} b_n. \quad (\text{A.2.4})$$

Note that if $\{a_n\}$ is not bounded from below, then $\overline{\lim}_{n \rightarrow \infty} a_n = -\infty$. Also, if $\{a_n\}$ is not bounded from above, we define $\overline{\lim}_{n \rightarrow \infty} a_n = \infty$. Hence, the $\overline{\lim}$ of any sequence always exists. Also, from the definition of the subsequence $\{b_n\}$, we have

$$a_n \leq b_n, \quad n = 1, 2, 3, \dots \quad (\text{A.2.5})$$

On the other hand, $\{c_n\}$ is a nondecreasing sequence. Hence, if $\{a_n\}$ is bounded from above, then the limit of c_n exists. We call the limit of $\{c_n\}$ the **limit infimum** (\liminf) of the sequence $\{a_n\}$ and write it as

$$\underline{\lim}_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} c_n. \quad (\text{A.2.6})$$

Note that if $\{a_n\}$ is not bounded from above, then $\underline{\lim}_{n \rightarrow \infty} a_n = \infty$. Also, if $\{a_n\}$ is not bounded from below, $\underline{\lim}_{n \rightarrow \infty} a_n = -\infty$. Hence, the $\underline{\lim}$ of any sequence always exists. Also, from the definition of the subsequences $\{c_n\}$ and $\{b_n\}$, we have

$$c_n \leq a_n \leq b_n, \quad n = 1, 2, 3, \dots \quad (\text{A.2.7})$$

Also, because $c_n \leq b_n$ for all n , we have

$$\underline{\lim}_{n \rightarrow \infty} a_n \leq \overline{\lim}_{n \rightarrow \infty} a_n. \quad \blacksquare \quad (\text{A.2.8})$$

Example A.2.1. Here are two examples. More are given in the exercises.

- Suppose $a_n = -n$ for all $n = 1, 2, \dots$. Then $b_n = \sup\{-n, -n-1, \dots\} = -n \rightarrow -\infty$ and $c_n = \inf\{-n, -n-1, \dots\} = -\infty \rightarrow -\infty$. So, $\underline{\lim}_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} a_n = -\infty$.

2. Suppose $\{a_n\}$ is defined by

$$a_n = \begin{cases} 1 + \frac{1}{n} & \text{if } n \text{ is even} \\ 2 + \frac{1}{n} & \text{if } n \text{ is odd.} \end{cases}$$

Then $\{b_n\}$ is the sequence $\{3, 2+(1/3), 2+(1/3), 2+(1/5), 2+(1/5), \dots\}$, which converges to 2, while $\{c_n\} \equiv 1$, which converges to 1. Thus, $\underline{\lim}_{n \rightarrow \infty} a_n = 1$ and $\overline{\lim}_{n \rightarrow \infty} a_n = 2$. ■

It is useful that the $\underline{\lim}_{n \rightarrow \infty}$ and $\overline{\lim}_{n \rightarrow \infty}$ of every sequence exists. Also, the sandwich effects of expressions (A.2.7) and (A.2.8) lead to the following theorem.

Theorem A.2.4. *Let $\{a_n\}$ be a sequence of real numbers. Then the limit of $\{a_n\}$ exists if and only if $\underline{\lim}_{n \rightarrow \infty} a_n = \overline{\lim}_{n \rightarrow \infty} a_n$, in which case, $\lim_{n \rightarrow \infty} a_n = \underline{\lim}_{n \rightarrow \infty} a_n = \overline{\lim}_{n \rightarrow \infty} a_n$.*

Proof: Suppose first that $\lim_{n \rightarrow \infty} a_n = a$. Because the sequences $\{c_n\}$ and $\{b_n\}$ are subsequences of $\{a_n\}$, Theorem A.2.2 implies that they converge to a also. Conversely, if $\underline{\lim}_{n \rightarrow \infty} a_n = \overline{\lim}_{n \rightarrow \infty} a_n$, then expression (A.2.7) and the Sandwich Theorem, A.2.1, imply the result. ■

Based on this last theorem, we have two interesting applications that are frequently used in statistics and probability. Let $\{p_n\}$ be a sequence of probabilities and let $b_n = \sup\{p_n, p_{n+1}, \dots\}$ and $c_n = \inf\{p_n, p_{n+1}, \dots\}$. For the first application, suppose we can show that $\overline{\lim}_{n \rightarrow \infty} p_n = 0$. Then, because $0 \leq p_n \leq b_n$, the Sandwich Theorem implies that $\lim_{n \rightarrow \infty} p_n = 0$. For the second application, suppose we can show that $\underline{\lim}_{n \rightarrow \infty} p_n = 1$. Then, because $c_n \leq p_n \leq 1$, the Sandwich Theorem implies that $\lim_{n \rightarrow \infty} p_n = 1$.

We list some other properties in a theorem and ask the reader to provide the proofs in Exercise A.2.2:

Theorem A.2.5. *Let $\{a_n\}$ and $\{d_n\}$ be sequences of real numbers. Then*

$$\overline{\lim}_{n \rightarrow \infty} (a_n + d_n) \leq \overline{\lim}_{n \rightarrow \infty} a_n + \overline{\lim}_{n \rightarrow \infty} d_n \quad (\text{A.2.9})$$

$$\underline{\lim}_{n \rightarrow \infty} a_n = -\overline{\lim}_{n \rightarrow \infty} (-a_n). \quad (\text{A.2.10})$$

EXERCISES

A.2.1. Calculate the $\underline{\lim}$ and $\overline{\lim}$ of each of the following sequences:

(a) For $n = 1, 2, \dots$, $a_n = (-1)^n \left(2 - \frac{4}{2^n}\right)$.

(b) For $n = 1, 2, \dots$, $a_n = n^{\cos(\pi n/2)}$.

(c) For $n = 1, 2, \dots$, $a_n = \frac{1}{n} + \cos \frac{\pi n}{2} + (-1)^n$.

A.2.2. Prove properties (A.2.9) and (A.2.10).

A.2.3. Let $\{a_n\}$ and $\{d_n\}$ be sequences of real numbers. Show that

$$\varliminf_{n \rightarrow \infty} (a_n + d_n) \geq \varliminf_{n \rightarrow \infty} a_n + \varliminf_{n \rightarrow \infty} d_n.$$

A.2.4. Let $\{a_n\}$ be a sequence of real numbers. Suppose $\{a_{n_k}\}$ is a subsequence of $\{a_n\}$. If $\{a_{n_k}\} \rightarrow a_0$ as $k \rightarrow \infty$, show that $\varliminf_{n \rightarrow \infty} a_n \leq a_0 \leq \varlimsup_{n \rightarrow \infty} a_n$.

Appendix B

R Primer

The package R can be downloaded at CRAN (<https://cran.r-project.org/>). It is freeware and there are versions for most platforms including Windows, Mac, and Linux. To install R simply follow the directions at CRAN. Installation should only take a few minutes. For more information on R, there are free downloadable manuals on its use at the CRAN website. There are many reference texts that the reader can consult, including the books by Venables and Ripley (2002), Verzani (2014), Crawley (2007), and Chapter 1 of Kloke and McKean (2014).

Once R is installed, in Windows, click on the R icon to begin an R session. The R prompt is a >. To exit R, type `q()`, which results in the query `Save workspace image? [y/n/c]::`. Upon typing y, the workspace will be saved for the next session. R has a built-in help (documentation) system. For example, to obtain help on the `mean` function, simply type `help(mean)`. To exit help, type `q`. We would recommend using R while working through the sections in this primer.

B.1 Basics

The commands of R work on numerical data, character strings, or logical types. To separate commands on the same line, use semicolons. Also, anything to the right of the symbol `#` is disregarded by R; i.e., to the right of `#` can be used for comments. Here are some arithmetic calculations:

```
> 8+6 - 7*2  
[1] 0  
  
> (150/3) + 7^2 -1 ; sqrt(50) - 50^(1/2)  
[1] 98  
  
[1] 0  
  
> (4/3)*pi*5^3    # The volume of a sphere with radius 5
```

```
[1] 523.5988
> 2*pi*5          # The circumference of a sphere with radius 5
[1] 31.41593
```

Results can be saved for later calculation by either the **assignment** function `<-` or equivalently the equal symbol `=`. Names can be a mixture of letters, numbers, or symbols. For example:

```
> r <- 10 ; Vol <- (4/3)*pi*r^3 ; Vol
[1] 4188.79
> r = 100 ; circum = 2*pi*r ; circum
[1] 628.3185
```

Variables in R include scalars, vectors, or matrices. In the last example the variables `r` and `Vol` are scalars. Scalars can be combined into vectors with the `c` function. Further, arithmetic functions on vectors are performed componentwise. For instance, here are two ways to compute the volumes of spheres with radii $5, 6, \dots, 9$.

```
> r <- c(5,6,7,8,9) ; Vol <- (4/3)*pi*r^3 ; Vol
[1] 523.5988 904.7787 1436.7550 2144.6606 3053.6281
> r <- 5:9 ; Vol <- (4/3)*pi*r^3 ; Vol
[1] 523.5988 904.7787 1436.7550 2144.6606 3053.6281
```

Components of a vector are referred to by using brackets. For example, the 5th component of the vector `vec` is `vec[5]`. Matrices can be formed from vectors using the commands `rbind` (combine rows) and `cbind` (combine columns) on vectors. To illustrate let **A** and **B** be the matrices

$$\mathbf{A} = \begin{bmatrix} 1 & 4 \\ 3 & 2 \end{bmatrix} \text{ and } \mathbf{B} = \begin{bmatrix} 1 & 3 & 5 & 7 \\ 2 & 4 & 6 & 8 \end{bmatrix}.$$

Then \mathbf{AB} , \mathbf{A}^{-1} , and $\mathbf{B}'\mathbf{A}$ are computed by

```
> c1 <- c(1,3) ; c2 <- c(4,2); a <- cbind(c1,c2)
> r1 <- c(1,3,5,7); r2 <- c(2,4,6,8); b <- rbind(r1,r2)
> a%*%b; solve(a) ; t(b)%*%a
```

```
[,1] [,2] [,3] [,4]
[1,]    9   19   29   39
[2,]    7   17   27   37

[,1] [,2]
c1 -0.2  0.4
c2  0.3 -0.1
```

```
c1 c2
[1,] 7 8
[2,] 15 20
[3,] 23 32
[4,] 31 44
```

Brackets are also used to refer to elements of matrices. Let `amat` be a 4×4 matrix. Then the (2, 3) element is `amat[2,3]` and the upper right corner 2×2 submatrix is `amat[1:2,3:4]`. This last item is an example of subsetting of a matrix. Subsetting is easy in R. For example, the following commands obtain the negative, positive, and elements of 0 for a vector `x`:

```
> x = c(-2,0,3,4,-7,-8,11,0); xn = x[x<0]; xn
[1] -2 -7 -8

> xp = x[x>0]; xp
[1] 3 4 11

> x0 = x[x==0]; x0
[1] 0 0
```

For R vectors `x` and `y` of the same length, the plot of `y` versus `x` is obtained by the command `plot(y ~ x)`. The following segment of R code obtains plots found in Figure 2.1.1 of the volume and circumference of the sphere versus the radius for a sequence of radii from 0 to 8 in steps of 0.1. The first plot is a simple plot; the second plot adds some labeling and a title; the third plot draws a curve of the relationship; and the fourth plot shows the relationship between the circumference of the circle versus the radius.

```
par(mfrow=c(2,2))      # This sets up a 2 by 2 page of plots
r <- seq(0,8,.1); Vol <- (4/3)*pi*r^3 ; plot(Vol ~ r)      # Plot 1
title("Simple Plot")
plot(Vol ~ r,xlab="Radius",ylab="Volume")                  # Plot 2
title("Volume vs Radius")
plot(Vol ~ r,pch=" ",xlab="Radius",ylab="Volume")
lines(Vol ~ r)                                              # Plot 3
title("Curve")
circum <- 2*pi*r
plot(circum ~ r,pch=" ",xlab="Radius",ylab="Circumference")
lines(circum ~ r); title("Circumference vs Radius")        # Plot 4
```

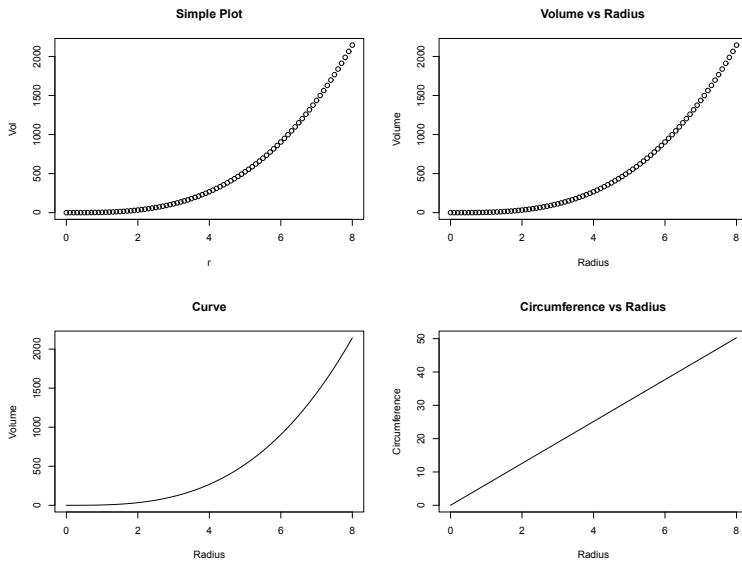

Figure 2.1.1: Spherical Plots discussed in Text.

B.2 Probability Distributions

For many distributions, R has functions that obtain probabilities, compute quantiles, and generate random variates. Here are two common examples. Let X be a random variable with a $N(\mu, \sigma^2)$ distribution. In R, let `mu` and `sig` denote the mean and standard deviation of X , respectively. Then the R commands and meanings are:

<code>pnorm(x,mu,sig)</code>	$P(X \leq x)$.
<code>qnorm(p,mu,sig)</code>	$P(X \leq q) = p$.
<code>dnorm(x,mu,sig)</code>	$f(x)$, where f is the pdf of X .
<code>rnorm(n,mu,sig)</code>	n variates generated from distribution of X .

As a numerical illustration, suppose the height of a male is normally distributed with mean 70 inches and standard deviation 4 inches.

```
> 1-pnorm(72,70,4)      # Prob. man exceeds 6 foot in ht.
[1] 0.3085375

> qnorm(.90,70,4)       # The upper 10th percentile in ht.
[1] 75.12621

> dnorm(72,70,4)        # value of density at 72
```

```
[1] 0.08801633
> rnorm(6,70,4)           # sample of size 6 on X
[1] 72.12486 75.25811 71.26661 63.36465 74.19436 69.71513
```

For the next figure, 2.2.2, we generate 100 variates, histogram the sample, and overlay the plot of the density of X on the histogram. Note the `pr=T` argument in the histogram. This scales the histogram to have area 1.

```
> x = rnorm(100,70,4); x=sort(x)
> hist(x,pr=T,main="Histogram of Sample")
> y = dnorm(x,70,4)
> lines(y~x)
```

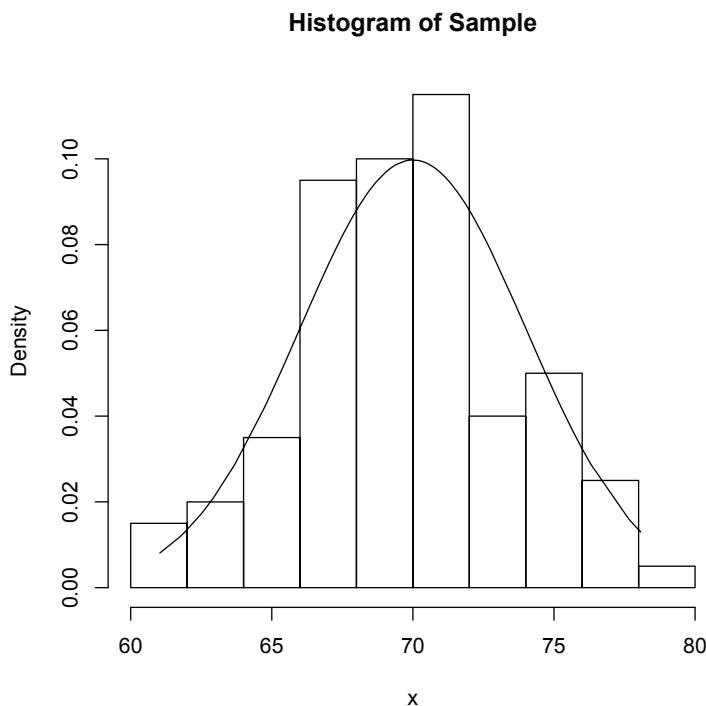

Figure 2.2.2: Histogram of a Random Sample from a $N(70, 4^2)$ distribution overlaid with the pdf of this normal.

For a discrete random variable the pdf is the probability mass function (pmf). Suppose X is binomial with 100 trials and 0.6 as the probability of success.

```
> pbinom(55,100,.6)      # Probability of at most 55 successes
[1] 0.1789016
> dbinom(55,100,.6)      # Probability of exactly 55 successes
[1] 0.04781118
```

Most other well known distributions are in core R. For example, here is the probability that a χ^2 random variable with 30 degrees of freedom exceeds 2 standard deviations from its mean, along with a Γ -distribution confirmation.

```
> mu=30; sig=sqrt(2*mu); 1-pchisq(mu+2*sig,30)
[1] 0.03471794
> 1-pgamma(mu+2*sig,15,1/2)
[1] 0.03471794
```

The `sample` command returns a random sample from a vector. It can either be sampling with replacement (`replace=T`) or sampling without replacement (`replace=F`). Here are samples of size 12 from the first 20 positive integers.

```
> vec = 1:20
> sample(vec,12,replace=T)
[1] 14 20  7 17  6  6 11 11  9  1 10 14
> sample(vec,12,replace=F)
[1] 12  1 14  5  4 11  3 17 16 19 20 15
```

B.3 R Functions

The syntax for R functions is the same as the syntax in R. This easily allows for the development of packages, a collection of R functions, for specific tasks. The schematic for an R function is

```
name=function <- function(arguments){
  ... body of function ...
}
```

Example B.3.1. Consider a process where a measurement is taken over time. At each time n , $n = 1, 2, \dots$, the measurement x_n is observed but only the sample mean $\bar{x}_n = (1/n) \sum_{i=1}^n x_i$ of the measurements at time n is recorded and the point (n, \bar{x}_n) is added to the running plot of sample means. How is this possible? There is a simple update formula for the sample mean that is easily derived. It is given by

$$\bar{x}_{n+1} = \frac{n}{n+1} \bar{x}_n + \frac{1}{n+1} x_{n+1}; \quad (\text{B.3.1})$$

hence, the sample mean for the sequence x_1, \dots, x_{n+1} can be expressed as a linear combination of the sample mean at time n and the $(n + 1)^{st}$ measurement. The following R function codes this update formula:

```
mnupdate <- function(n,xbarn,xnp1){
#   Input: n is sample size; xbarn is mean of sample of size n;
#          xnp1 is (n+1) (new) observation
#   Output: mean of sample of size (n+1)
  mnupdate <- (n/(n+1))*xbarn + xnp1/(n+1)
  return(mnupdate)
}
```

To run this function we first source it in R. If the function is in the file `mnupdate.R` in the current directory then the source command is `source("mnupdate.R")`. It can also be copied and pasted into the current R session. Here is an execution of it:

```
> source("mnupdate.R")
> x = c(3,5,12,4); n=4; xbarn = mean(x);
> x; xbarn           #Old sample and its mean
[1] 3 5 12 4
[1] 6
> xp1 = 30           # New observation
> mnupdate(n,xbarn,xp1)    # Mean of updated sample
[1] 10.8
```

■

B.4 Loops

Occasionally in the text, we use a loop in an R program to compute a result. Usually it is a simple `for` loop of the form

```
for(i in 1:n){
  ... R code often as a function of i ...
  # For the n-iterations of the loop, i runs through
  # the values i=1, i=2, ... , i=n.
}
```

For example, the following code segment produces a table of squares, cubes, square-roots, and cube-roots, for the integers from 1 to n .

```
# set n at some value
tab <- c()           # Initialize the table
for(i in 1:n){
  tab <- rbind(tab,c(i,i^2,i^3,i^(1/2),i^(1/3)))
}
tab
```

B.5 Input and Output

Many texts on R, including the references cited above, have information on input and output (I/O) in R. We only discuss several ways which are useful for the R discussion in our text. For output, we discuss two commands. The first writes an array (matrix) to a text file. Suppose `amat` is a matrix with p columns. Then the command `write(t(amat),ncol=p,file="amatrix.dat")` writes the matrix `amat` to the text file `amatrix.dat` in the current directory. Simply put the “Path” before the file as `file="Path/amatrix.dat"` to send it to another directory. The second way writes out variables to an R object file called an “rda” file. The variables can include scalars, vectors, matrices, and strings. For example the next line of code writes to an rda file the scalars `avar` and `bscale` and the matrix `amat` along with an information string.

```
info <- "This file contains the variable ....."
save(avar,bscale,amat,info,file="try.rda")
```

The command `load("try.rda")` will load these variables (names and values) into the current session. Most of the data sets discussed in the text are in rda files.

For input, we have already discussed the `c` and `load` functions. The `c` function is tedious, though, and a much easier way is to use the `scan` function. For example, the following lines of code assign the vector $(1, 2, 3)$ to `x`:

```
x <- scan()
1   2
3
```

The separator between values is white space and the empty line after the data signals the end of `x`'s values. Note that this allows data to be copied and pasted into R. A matrix can also be scanned similarly by using the `read.table` function; for example, the following command inputs the above matrix `A` with column header “c1” and “c2”:

```
a <- read.table(header = TRUE, text =
  c1 c2
  1  4
  3  2
  ")
```

Notice that copy and paste is also easily used with this command. If the matrix `A` is in the file `amat.dat` with no header, it can be read in as

```
a <- matrix(scan("amat.dat"),ncol=2,byrow=T)
```

B.6 Packages

An R package is a collection of R functions designed for specified tasks. For example, in Chapter 10, the packages `Rfit` and `npsm` are discussed that compute rank-based

robust and nonparametric procedures. There are thousands of free packages available to users at the site CRAN. The package `hmcpkg` contains all the R functions and R data sets discussed in this text. It can be downloaded at the site:

<http://www.stat.wmich.edu/mckean/hmchomepage/Pkg/>

Once it is installed on your computer use the library command as shown next to use the package in an R session. The next segment of code prints out the first 3 lines of the baseball data set discussed in Example 4.2.4. The attach command allows us to access the variables of the data set, as we show for the variable `height`.

```
library(hmcpkg)
head(bb,3)
hand height weight hitind hitpitind average
1    1     74     218      1        0   3.330
2    0     75     185      1        1   0.286
3    1     77     219      2        0   3.040
attach(bb); head(height,4)  # accessing the variable height
[1] 74 75 77 73
```

In Example 1.3.3, the derivation of the probability that in a group of n people at least 2 have the same birthday is given. The R function `bday`, included in the package, computes this probability. The following segment of code computes it for a group of size 10.

```
library(hmcpkg)
bday(10)
[1] 0.1169482
```

Appendix C

Lists of Common Distributions

In this appendix, we provide a short list of common distributions. For each distribution, we note the expression where the pmf or pdf is defined in the text, the formula for the pmf or pdf, its mean and variance, and its mgf. The first list contains common discrete distributions, and the second list contains common continuous distributions.

List of Common Discrete Distributions

Bernoulli

$$0 < p < 1$$

(3.1.1)

$$p(x) = p^x(1-p)^{1-x}, \quad x = 0, 1$$

$$\mu = p, \quad \sigma^2 = p(1-p)$$

$$m(t) = [(1-p) + pe^t], \quad -\infty < t < \infty$$

Binomial

$$0 < p < 1$$

$$n = 1, 2, \dots$$

(3.1.2)

$$p(x) = \binom{n}{x} p^x (1-p)^{n-x}, \quad x = 0, 1, 2, \dots, n$$

$$\mu = np, \quad \sigma^2 = np(1-p)$$

$$m(t) = [(1-p) + pe^t]^n, \quad -\infty < t < \infty$$

Geometric

$$0 < p < 1$$

(3.1.4)

$$p(x) = p(1-p)^x, \quad x = 0, 1, 2, \dots$$

$$\mu = \frac{q}{p}, \quad \sigma^2 = \frac{1-p}{p^2}$$

$$m(t) = p[1 - (1-p)e^t]^{-1}, \quad t < -\log(1-p)$$

Hypergeometric (N, D, n)

$$n = 1, 2, \dots, \min\{N, D\}$$

(3.1.7)

$$p(x) = \frac{\binom{N-D}{n-x} \binom{D}{x}}{\binom{N}{n}}, \quad x = 0, 1, 2, \dots, n$$

$$\mu = n \frac{D}{N}, \quad \sigma^2 = n \frac{D}{N} \frac{N-D}{N} \frac{N-n}{N-1}$$

The above pmf is the probability of obtaining x D s in a sample of size n , without replacement.

Negative Binomial

$$0 < p < 1$$

$$r = 1, 2, \dots$$

(3.1.3)

$$p(x) = \binom{x+r-1}{r-1} p^r (1-p)^x, \quad x = 0, 1, 2, \dots$$

$$\mu = \frac{rq}{p}, \quad \sigma^2 = \frac{r(1-p)}{p^2}$$

$$m(t) = p^r [1 - (1-p)e^t]^{-r}, \quad t < -\log(1-p)$$

Poisson

$$m > 0$$

(3.2.1)

$$p(x) = e^{-m} \frac{m^x}{x!}, \quad x = 0, 1, 2, \dots$$

$$\mu = m, \quad \sigma^2 = m$$

$$m(t) = \exp\{m(e^t - 1)\}, \quad -\infty < t < \infty$$

List of Common Continuous Distributions

beta	(3.3.9)
$\alpha > 0$	$f(x) = \frac{\Gamma(\alpha+\beta)}{\Gamma(\alpha)\Gamma(\beta)} x^{\alpha-1} (1-x)^{\beta-1}, \quad 0 < x < 1$
$\beta > 0$	$\mu = \frac{\alpha}{\alpha+\beta}, \quad \sigma^2 = \frac{\alpha\beta}{(\alpha+\beta+1)(\alpha+\beta)^2}$
	$m(t) = 1 + \sum_{i=1}^{\infty} \left(\prod_{j=0}^{k-1} \frac{\alpha+j}{\alpha+\beta+j} \right) \frac{t^i}{i!}, \quad -\infty < t < \infty$

Cauchy	(1.9.2)
	$f(x) = \frac{1}{\pi} \frac{1}{x^2+1}, \quad -\infty < x < \infty$
	Neither the mean nor the variance exists.
	The mgf does not exist.

Chi-squared, $\chi^2(r)$	(3.3.7)
$r > 0$	$f(x) = \frac{1}{\Gamma(r/2)2^{r/2}} x^{(r/2)-1} e^{-x/2}, \quad x > 0$
	$\mu = r, \quad \sigma^2 = 2r$
	$m(t) = (1-2t)^{-r/2}, \quad t < \frac{1}{2}$
	$\chi^2(r) \Leftrightarrow \Gamma(r/2, 2)$
	r is called the degrees of freedom.

Exponential	(3.3.6)
$\lambda > 0$	$f(x) = \lambda e^{-\lambda x}, \quad x > 0$
	$\mu = \frac{1}{\lambda}, \quad \sigma^2 = \frac{1}{\lambda^2}$
	$m(t) = [1 - (t/\lambda)]^{-1}, \quad t < \lambda$
	$\text{Exponential}(\lambda) \Leftrightarrow \Gamma(1, 1/\lambda)$

$F, F(r_1, r_2)$	(3.6.6)
$r_1 > 0$	$f(x) = \frac{\Gamma[(r_1+r_2)/2](r_1/r_2)^{r_1/2}}{\Gamma(r_1/2)\Gamma(r_2/2)} \frac{(x)^{r_1/2-1}}{(1+r_1x/r_2)^{(r_1+r_2)/2}}, \quad x > 0$
$r_2 > 0 > 0$	If $r_2 > 2$, $\mu = \frac{r_2}{r_2-2}$. If $r > 4$, $\sigma^2 = 2 \left(\frac{r_2}{r_2-2} \right)^2 \frac{r_1+r_2-2}{r_1(r_2-4)}$.
	The mgf does not exist.
	r_1 is called the numerator degrees of freedom.
	r_2 is called the denominator degrees of freedom.

Gamma, $\Gamma(\alpha, \beta)$	(3.3.2)
$\alpha > 0$	$f(x) = \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta}, \quad x > 0$
$\beta > 0$	$\mu = \alpha\beta, \quad \sigma^2 = \alpha\beta^2$
	$m(t) = (1-\beta t)^{-\alpha}, \quad t < \frac{1}{\beta}$

Continuous Distributions, Continued

Laplace (2.2.4)
 $-\infty < \theta < \infty$
 $f(x) = \frac{1}{2} e^{-|x-\theta|}, \quad -\infty < x < \infty$
 $\mu = \theta, \quad \sigma^2 = 2$
 $m(t) = e^{t\theta} \frac{1}{1-t^2}, \quad -1 < t < 1$

Logistic (6.1.8)
 $-\infty < \theta < \infty$
 $f(x) = \frac{\exp\{-\frac{(x-\theta)}{2}\}}{(1+\exp\{-\frac{(x-\theta)}{2}\})^2}, \quad -\infty < x < \infty$
 $\mu = \theta, \quad \sigma^2 = \frac{\pi^2}{3}$
 $m(t) = e^{t\theta} \Gamma(1-t)\Gamma(1+t), \quad -1 < t < 1$

Normal, $N(\mu, \sigma^2)$ (3.4.6)
 $-\infty < \mu < \infty$
 $f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left\{-\frac{1}{2} \left(\frac{x-\mu}{\sigma}\right)^2\right\}, \quad -\infty < x < \infty$
 $\sigma > 0$
 $\mu = \mu, \quad \sigma^2 = \sigma^2$
 $m(t) = \exp\{\mu t + (1/2)\sigma^2 t^2\}, \quad -\infty < t < \infty$

$t, t(r)$ (3.6.2)
 $r > 0$
 $f(x) = \frac{\Gamma[(r+1)/2]}{\sqrt{\pi r} \Gamma(r/2)} \frac{1}{(1+x^2/r)^{(r+1)/2}}, \quad -\infty < x < \infty$
If $r > 1$, $\mu = 0$. If $r > 2$, $\sigma^2 = \frac{r}{r-2}$.
The mgf does not exist.
The parameter r is called the degrees of freedom.

Uniform (1.7.4)
 $-\infty < a < b < \infty$
 $f(x) = \frac{1}{b-a}, \quad a < x < b$
 $\mu = \frac{a+b}{2}, \quad \sigma^2 = \frac{(b-a)^2}{12}$
 $m(t) = \frac{e^{bt}-e^{at}}{(b-a)t}, \quad -\infty < t < \infty$

Appendix D

Tables of Distributions

Prior to the current age of computing, probability tables for certain distributions were part of many text books in probability and statistics. These are not needed any longer. Most statistical computing packages offer easy-to-use calls to determine these probabilities and quantiles. This is certainly true of the language R as we have discussed through out this text. Also, many hand calculators have such functions.

Tables for the following distributions are presented:

Table I Selected quantiles for chi-square distributions.

Table II Cumulative distribution function for the standard normal random variable.

Table III Selected quantiles for t -distributions.

Table IV Selected quantiles for F -distributions.

Table I
Chi-Square Distribution

The following table presents selected quantiles of chi-square distribution, i.e., the values x such that

$$P(X \leq x) = \int_0^x \frac{1}{\Gamma(r/2)2^{r/2}} w^{r/2-1} e^{-w/2} dw,$$

for selected degrees of freedom r . The R function `chistable.s` generates this table.

r	$P(X \leq x)$

Table II
Normal Distribution

The following table presents the standard normal distribution. The probabilities tabled are

$$P(Z \leq z) = \Phi(z) = \int_{-\infty}^z \frac{1}{\sqrt{2\pi}} e^{-w^2/2} dw.$$

Note that only the probabilities for $z \geq 0$ are tabled. To obtain the probabilities for $z < 0$, use the identity $\Phi(-z) = 1 - \Phi(z)$. At the bottom of the table, some useful quantiles of the standard normal distribution are displayed. The R function `normaltable.s` generates this table.

z	0.00	0.01	0.02	0.03	0.04	0.05	0.06	0.07	0.08	0.09
0.0	.5000	.5040	.5080	.5120	.5160	.5199	.5239	.5279	.5319	.5359

Table III
***t*-Distribution**

The following table presents selected quantiles of the *t*-distribution, i.e., the values t such that

$$P(T \leq t) = \int_{-\infty}^t \frac{\Gamma[(r+1)/2]}{\sqrt{\pi r} \Gamma(r/2) (1 + w^2/r)^{(r+1)/2}} dw,$$

for selected degrees of freedom r . The last row gives the standard normal quantiles.

r	$P(T \leq t)$					
	0.900	0.950	0.975	0.990	0.995	0.999

Table IV
F-Distribution
Upper 0.05 Critical Points

The following table presents selected 0.95 and 0.99 quantiles of the F -distribution, i.e., for $\alpha = 0.05, 0.01$, the values $F_\alpha(r_1, r_2)$ such that

$$\alpha = P(X \geq F_\alpha(r_1, r_2)) = \int_{F_\alpha(r_1, r_2)}^{\infty} \frac{\Gamma[(r_1 + r_2)/2](r_1/r_2)^{r_1/2} w^{r_1/2-1}}{\Gamma(r_1/2)\Gamma(r_2/2)(1 + r_1 w/r_2)^{(r_1+r_2)/2}} dw,$$

where r_1 and r_2 are the numerator and denominator degrees of freedom, respectively. The R function `fp1.r` generates this table.

Answers to Selected Exercises

Chapter 1

- 1.2.1** (a) $\{0, 1, 2, 3, 4\}$, $\{2\}$; (b) $(0, 3)$,
 $\{x : 1 \leq x < 2\}$;
(c) $\{(x, y) : 1 < x < 2, 1 < y < 2\}$.
- 1.2.2** (a) $\{x : 0 < x \leq 5/8\}$.
- 1.2.3** $C_1 \cap C_2 = \{mary, mray\}$.
- 1.2.4** (c) $(\cup A_n)^c = \cap A_n^C$; $(\cap A_n)^c = \cup A_n^C$.
- 1.2.6** (a) $\{x : 0 < x < 3\}$,
(b) $\{(x, y) : 0 < x^2 + y^2 < 4\}$.
- 1.2.7** (a) $\{x : x = 2\}$, (b) ϕ ,
(c) $\{(x, y) : x = 0, y = 0\}$.
- 1.2.8** (a) $\frac{80}{81}$, (b) 1.
- 1.2.9** $\frac{11}{16}, 0, 1$.
- 1.2.10** $\frac{8}{3}, 0, \frac{\pi}{2}$.
- 1.2.11** (a) $\frac{1}{2}$, (b) 0, (c) $\frac{2}{9}$.
- 1.2.12** (a) $\frac{1}{6}$, (b) 0.
- 1.2.14** 10.
- 1.3.2** $\frac{1}{4}, \frac{1}{13}, \frac{1}{52}, \frac{4}{13}$.
- 1.3.3** $\frac{31}{32}, \frac{3}{64}, \frac{1}{32}, \frac{63}{64}$.
- 1.3.4** 0.3.
- 1.3.5** $e^{-4}, 1 - e^{-4}, 1$.
- 1.3.6** $\frac{1}{2}$.
- 1.3.10** (a) $\binom{6}{4}/\binom{16}{4}$, (b) $\binom{10}{4}/\binom{16}{4}$.
- 1.3.11** $1 - \binom{990}{5}/\binom{1000}{5}$.
- 1.3.13** (b) $1 - \binom{10}{3}/\binom{20}{3}$.
- 1.3.15** (a) $1 - \binom{48}{5}/\binom{50}{5}$.
- 1.3.16** $n = 23$.
- 1.3.19** $13 \cdot 12 \binom{4}{3} \binom{4}{2}/\binom{52}{5}$.
- 1.3.22** (a) $0 \leq \sum_{i=1}^3 p_i \leq 1$, (b) no.
- 1.4.3** $\frac{9}{47}$.
- 1.4.4** $2 \frac{13}{52} \frac{12}{51} \frac{26}{50} \frac{25}{49}$.
- 1.4.6** $\frac{111}{143}$.
- 1.4.8** (a) 0.022, (b) $\frac{5}{11}$.
- 1.4.9** $\frac{5}{14}$.
- 1.4.10** $\frac{3}{7}, \frac{4}{7}$.
- 1.4.12** (c) 0.88.
- 1.4.14** (a) 0.1764.
- 1.4.15** $4(0.7)^3(0.3)$.
- 1.4.16** 0.75.

1.4.18 (a) $\frac{6}{11}$.

1.4.20 $\frac{1}{7}$.

1.4.21 (a) $1 - \left(\frac{5}{6}\right)^6$, (b) $1 - e^{-1}$.

1.4.23 $\frac{3}{4}$.

1.4.25 $\frac{43}{64}$.

1.4.27 (a) $\sum_{x=1}^{20} 4/[20(25 - (x-1))]$
 (b) `x=1:20; sum(4/((25-x+1)*20))`
 (c) Download `ex1427.R`

1.4.28 $\frac{5.4 \cdot 5.4 \cdot 3}{10 \cdot 9 \cdot 8 \cdot 7 \cdot 6}$.

1.4.29 $\frac{13}{4}$.

1.4.30 $\frac{2}{3}$.

1.4.31 0.518, 0.491.

1.4.32 No.

1.5.1 $\frac{9}{13}, \frac{1}{13}, \frac{1}{13}, \frac{1}{13}, \frac{1}{13}$.

1.5.2 (a) $\frac{1}{2}$, (b) $\frac{1}{21}$.

1.5.3 $\frac{1}{5}, \frac{1}{5}, \frac{1}{5}$.

1.5.5 (a) $\frac{\binom{13}{x} \binom{39}{5-x}}{\binom{52}{5}}, x = 0, 1, 2, 3, 4, 5$,
 (b) $[(\binom{39}{5}) + (\binom{13}{1})(\binom{39}{4})] / \binom{52}{5}$.

1.5.7 $\frac{3}{4}$.

1.5.8 For the plot download `ex158.R`

(a) $\frac{1}{4}$, (b) 0, (c) $\frac{1}{4}$, (d) 0.

1.6.2 (a) $p_X(x) = \frac{1}{10}, x = 1, 2, \dots, 10$,
 (b) $\frac{4}{10}$.

1.6.3 (a) $\left(\frac{5}{6}\right)^{x-1} \frac{1}{6} x = 1, 2, 3, \dots$,
 (c) $\frac{6}{11}$.

1.6.4 $\frac{6}{36}, x = 0; \frac{12-2x}{36}, x = 1, 2, 3, 4, 5$.

1.6.5 (a) Download `dex165.R`.

1.6.7 $\frac{1}{3}, y = 3, 5, 7$.

1.6.8 $\left(\frac{1}{2}\right)^{\sqrt[3]{y}}, y = 1, 8, 27, \dots$

1.7.1 $F(x) = \frac{\sqrt{x}}{10}, 0 \leq x < 100$;
 $f(x) = \frac{1}{20\sqrt{x}}, 0 < x < 100$.

1.7.3 $\frac{5}{8}; \frac{7}{8}; \frac{3}{8}$.

1.7.5 $e^{-2} - e^{-3}$.

1.7.6 (a) $\frac{1}{27}, 1$; (b) $\frac{2}{9}, \frac{25}{36}$.

1.7.8 (a) 1; (b) $\frac{2}{3}$; (c) 2.

1.7.10 $\sqrt[4]{0.2}$.

1.7.12 (a) $1 - (1-x)^3, 0 \leq x < 1$;
 (b) $1 - \frac{1}{x}, 1 \leq x < \infty$.

1.7.13 $xe^{-x}, 0 < x < \infty$; mode is 1.

1.7.14 $\frac{7}{12}$.

1.7.17 $\frac{1}{2}$.

1.7.19 $-\sqrt{2}$.

1.7.20 (b) $f_y(y) = 1/(5+y)^{1.2}$.
 (c) `dlife <- function(y){1/(5+y)^(1.2)}`.

1.7.21 (a) $f(x) = (5/3)e^{-x}/[1+(2/3)e^{-x}]^{(7/2)}$.
 (b) `f=function(x){(1+(2/3)*exp(-x))^{(-5/2)}}`

1.7.22 $\frac{1}{27}, 0 < y < 27$.

1.7.24 $\frac{1}{\pi(1+y^2)}, -\infty < y < \infty$.

1.7.25 cdf $1 - e^{-y}, 0 \leq y < \infty$.
1.7.26 pdf $\frac{1}{3\sqrt{y}}, 0 < y < 1$,
 $\frac{1}{6\sqrt{y}}, 1 < y < 4$.

1.8.3 2, 86.4, -160.8.

1.8.4 3, 11, 27.

1.8.5 $\frac{\log 100.5 - \log 50.5}{50}$.

1.8.6 (a) $\frac{3}{4}$; (b) $\frac{1}{4}, \frac{1}{2}$.

1.8.7 $\frac{3}{20}$.

1.8.8 \$7.80.**1.8.9** (a) 2; (b) pdf is $\frac{2}{y^3}$, $1 < y < \infty$;
(c) 2.**1.8.10** $\frac{7}{3}$.**1.8.12** (a) $\frac{1}{2}$; (c) $\frac{1}{2}$.**1.8.13** $P[G = -p_0] = \frac{1}{3}$, $P[G = 1 - p_0] = \frac{2}{3}\frac{1}{2}$,
 $\dots, P[G = 50 - p_0] = \frac{2}{3}\frac{1}{2}(0.0045)$.**1.8.14** Range of G : $\{2 - p_0, 5 - p_0, 8 - p_0\}$, Probs: $\frac{3}{10}, \frac{6}{10}, \frac{1}{10}$.**1.9.1** (a) 1.5, 0.75; (b) 0.5, 0.05;
(c) 2, does not exist.**1.9.2** $\frac{e^t}{2-e^t}$, $t < \log 2$; 2; 2.**1.9.12** 10; 0; 2; -30.**1.9.14** (a) $-\frac{2\sqrt{2}}{5}$; (b) 0; (c) $\frac{2\sqrt{2}}{5}$.**1.9.16** $\frac{1}{2p}; \frac{3}{2}; \frac{5}{2}; 5; 50$.**1.9.18** $\frac{31}{12}, \frac{167}{144}$.**1.9.19** $E(X^r) = \frac{(r+2)!}{2}$.**1.9.20** odd moments are 0, $E(X^{2n}) = (2n)!$.**1.9.24** $\frac{5}{8}; \frac{37}{192}$.**1.9.27** $(1 - \beta t)^{-1}, \beta, \beta^2$.**1.10.3** 0.84.**1.10.4** $P(|X| \geq 5) = 0.0067$.

Chapter 2

2.1.1 $\frac{15}{64}; 0; \frac{1}{2}; \frac{1}{2}$.**2.1.2** $\frac{1}{4}$.**2.1.7** $ze^{-z}, 0 < z < \infty$.**2.1.8** $-\log z, 0 < z < 1$.**2.1.9** $\binom{13}{x} \binom{13}{y} \binom{26}{13-x-y} / \binom{52}{13}$,
 x and y nonnegative integers

- 6.5.1** $t = -8.64$, p -value = 0.0001.

7.4.3 Y/n .

- 6.5.2** (81.30004, 81.30156).

7.4.5 $Y_1 - \frac{1}{n}$.

- 6.5.3** (b) (-0.0249, 0.1749).

7.4.7 (a) Yes; (b) yes.

- 6.5.6** (b) $c \frac{\sum_{i=1}^n X_i^2}{\sum_{i=1}^m Y_i^2}$.

7.4.8 (a) $E(X) = 0$.

- 6.5.7** $F = \frac{\bar{X}}{\bar{Y}}$.

7.4.9 (a) $\max\{-Y_1, 0.5Y_n\}$; (b) yes;
 (c) yes.

- 6.5.8** (b) $F = \bar{x}/\bar{y} = 0.3389$, Reject.

7.5.1 $Y_1 = \sum_{i=1}^n X_i; Y_1/4n$; yes.

- 6.5.9** $c \frac{[\max\{-X_1, X_{n_1}\}]^{n_1} [\max\{-Y_1, Y_{n_2}\}]^{n_2}}{[\max\{-X_1, -Y_1, X_{n_1}, Y_{n_2}\}]^{n_1+n_2}}, \chi^2(2)$.

7.5.4 \bar{x}/α .

- 6.6.8** The R function `mixnormal`, at site listed in the Preface, produced these results:

7.5.9 \bar{x} .

(first row are initial estimates, second row are the estimates after 500 iterations):

- 7.5.11** (b) Y_1/n ; (c) θ ; (d) Y_1/n .

7.6.1 $\bar{X}^2 - \frac{1}{n}$.

7.6.2 $Y^2/(n^2 + 2n)$.

- 7.6.3** (a) 0.8413; (b) 0.7702 (c) Our run 0.0584.
- 7.6.4** (a) 49.4; (b) Our run: 4.405
- 7.6.6** (a) $\left(\frac{n-1}{n}\right)^Y \left(1 + \frac{Y}{n-1}\right)$;
 (b) $\left(\frac{n-1}{n}\right)^{n\bar{X}} \left(1 + \frac{n\bar{X}}{n-1}\right)$;
 (c) $N\left(\theta, \frac{\theta}{n}\right)$.
- 7.6.9** $1 - e^{-2/\bar{X}}$; $1 - \left(1 - \frac{2/\bar{X}}{n}\right)^{n-1}$.
- 7.6.10** (b) \bar{X} ; (c) \bar{X} ; (d) $1/\bar{X}$.
- 7.7.3** Yes.
- 7.7.5** (a) $\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]} \sqrt{\frac{n-1}{2}} S$.
 (b) Download `bootse6.R`
 10.1837; Our run: 1.156828
- 7.7.6** (b) $\frac{Y_1+Y_n}{2}; \frac{(n+1)(Y_n-Y_1)}{2(n-1)}$.
- 7.7.7** (a) $K = (\Gamma((n-1)/2)/\Gamma(n/2)) \times \sqrt{\pi}((n-1)/2)$
 mvue = $\Phi^{-1}(p)KS + \bar{x}$
 (c) 59.727; Our run 3.291479.
- 7.7.9** (a) $\frac{1}{n-1} \sum_{h=1}^n (X_{ih} - \bar{X}_i) \times (X_{jh} - \bar{X}_j)$;
 (b) $\sum_{i=1}^n a_i \bar{X}_i$.
- 7.7.10** $\left(\sum_{i=1}^n x_i, \sum_{i=1}^n \frac{1}{x_i}\right)$.
- 7.8.3** $Y_1, ; \sum_{i=1}^n (Y_i - Y_1)/n$.
- 7.9.13** (a) $\Gamma(3n, 1/\theta)$, no;
 (c) $(3n-1)/Y$;
 (e) Beta($3, 3n-3$).
- Chapter 8**
- 8.1.4** $\sum_{i=1}^{10} x_i^2 \geq 18.3$; yes; yes.
- 8.1.5** $\prod_{i=1}^n x_i \geq c$.
- 8.1.6** $3 \sum_{i=1}^{10} x_i^2 + 2 \sum_{i=1}^{10} x_i \geq c$.
- 8.1.7** About 96; 76.7.
- 8.1.8** $\prod_{i=1}^n [x_i(1-x_i)] \geq c$.
- 8.1.9** About 39; 15.
- 8.1.10** 0.08; 0.875.
- 8.2.1** $(1-\theta)^9(1+9\theta)$.
- 8.2.2** $1 - \frac{15}{16\theta^4}, 1 < \theta$.
- 8.2.3** $1 - \Phi\left(\frac{3-5\theta}{2}\right)$.
- 8.2.4** About 54; 5.6.
- 8.2.7** Reject H_0 if $\bar{x} \geq 77.564$.
- 8.2.8** About 27; reject H_0 if $\bar{x} \leq 24$.
- 8.2.10** $\Gamma(n, \theta)$;
 Reject H_0 if $\sum_{i=1}^n x_i \geq c$.
- 8.2.12** (b) $\frac{6}{32}$; (c) $\frac{1}{32}$.
 (d) reject if $y = 0$;
 if $y = 1$, reject with probability $\frac{1}{5}$.
- 8.3.1** (b) $t = -2.2854, p = 0.02393$;
 (c) $(-0.5396 - 0.0388)$.
- 8.3.5** (d) $n = 90$.
- 8.3.6** 78; 0.7608.
- 8.3.10** Under H_1 , $(\theta_4/\theta_3)F$ has an $F(n-1, m-1)$ distribution.
- 8.3.12** Reject H_0 if $|y_3 - \theta_0| \geq c$.
- 8.3.14** (a) $\prod_{i=1}^n (1-x_i) \geq c$.
- 8.3.17** (b) $F = 1.34; p = 0.088$.
- 8.4.1** $5.84n - 32.42; 5.84n + 41.62$.
- 8.4.2** $0.04n - 1.66; 0.04n + 1.20$.
- 8.4.4** 0.025, 29.7, -29.7.
- 8.5.5** $(9y - 20x)/30 \leq c \Rightarrow (x, y) \in \text{2nd}$.
- 8.5.7** $2w_1^2 + 8w_2^2 \geq c \Rightarrow (w_1, w_2) \in \text{II}$.
- Chapter 9**
- 9.2.3** 6.39.
- 9.2.6** (b) $F = 1.1433, p = 0.3451$.
- 9.2.7** $7.875 > 4.26$; reject H_0 .
- 9.2.8** $10.224 > 4.26$; reject H_0 .

9.3.2 $2r + 4\theta$.**9.3.3** (a) $5m/3$; (b) 0.6174; 0.9421;
(c) 7**9.4.1** None. For $B - C$: $(-0.199, 10.252)$.**9.4.2** No significant differences.**9.4.3** (a) CI's of form: (4.2.14) using α/k .**9.4.4** (a) $(-0.103, 0.0214)$
(b) $\chi^2 = 24.4309$, $p = 0.00367$,
 $(-0.103, 0.021)$.**9.5.6** 7.00; 9.98.**9.5.8** 4.79; 22.82; 30.73.**9.5.10** (a) $7.624 > 4.46$, reject H_A ;

(zeroes were excluded).**10.8.10** $r_N = 0.835$; $z = 3.734$.**10.9.4** Cases: $t < y$ and $t > y$.**10.9.5** (c) $y^2 - \sigma^2$.**10.9.7** (a) $n^{-1} \sum_{i=1}^n (Y_i - \bar{Y})^2$;
(c) $y^2 - \sigma^2$.

10.9.9 0; $[4f^2(\theta)]^{-1}$.

10.9.14 $\hat{y}_{LS} = 3.14 + .028x$;
 $\hat{y}_W = 0.214 + .020x$.

Chapter 11

11.1.1 0.45; 0.55.

11.1.3 $[y\tau^2 + \mu\sigma^2/n]/(\tau^2 + \sigma^2/n)$.

11.1.4 $\beta(y + \alpha)/(n\beta + 1)$.

11.1.6 $\frac{y_1 + \alpha_1}{n + \alpha_1 + \alpha_2 + \alpha_3}; \frac{y_2 + \alpha_2}{n + \alpha_1 + \alpha_2 + \alpha_3}$.

11.1.8 (a) $(\theta - \frac{10+30\theta}{45})^2 + (\frac{1}{45})^2 30\theta(1-\theta)$.

11.1.9 $\sqrt[6]{2}, y_4 < 1; \sqrt[6]{2}y_4, 1 \leq y_4$.

11.2.1 (a) $\frac{\theta_2^2}{[\theta_2^2 + (x_1 - \theta_1)^2][\theta_2^2 + (x_2 - \theta_1)^2]}$.

11.2.3 (a) 76.84; (b) (76.25, 77.43).

11.2.5 (a) $I(\theta) = \theta^{-2}$; (d) $\chi^2(2n)$.

11.2.8 (a) beta($n\bar{x} + 1, n + 1 - n\bar{x}$).

11.3.1 (a) Let U_1 and U_2 be iid uniform(0,1):

1. Draw $Y = -\log(1 - U_1)$
2. Draw $X = Y - \log(1 - U_2)$.

11.3.3 (b) $F_X^{-1}(u) = -\log(1 - \sqrt{u})$,
 $0 < u < 1$.

11.3.7 (b) $f(x|y)$ is a $b(n, y)$ pmf;
 $f(y|x)$ is a beta($x + \alpha, n - x + \beta$) pdf.

11.4.1 (b) $\hat{\beta} = \frac{1}{2\bar{x}}$; (d) $\hat{\theta} = \frac{1}{\bar{x}}$.

11.4.2 (a) $\delta(y) = \frac{\int_0^1 \left[\frac{a}{1-a \log p} \right]^2 p^y (1-p)^{n-y} dp}{\int_0^1 \left[\frac{a}{1-a \log p} \right]^2 p^{y-1} (1-p)^{n-y} dp}$.
